Part I.

Sentences, Sets, and Order

Chapter 1.

Sentences

1.1. Basic Characteristics of Sentences

Colloquially, we observe the occurrences in nature via our senses and brain, possibly aided by instruments. The concepts we have about the world enable us to specify and communicate via speech or exposition the various phenomena. The current exposition contains *constants* (representing specific things within a specified context) in form of symbols and words which have a generally understood meaning by themselves, and *variables*, which do not have sufficient meaning by themselves.

Example 1.1. We will treat the number π as a mathematical constant.

Example 1.2. The symbol x in 'x pebbles' and the symbol φ in 'We say that φ.' are variables.

In this exposition, we typically include mathematical constants in a *sentence* (such as the one in Example 1.1), and we will require sentences to satisfy *two-valued logic* in the following sense.

Principle 1.1 (Principle of Bivalence, truth value, true, false). "[T]he *principle of bivalence* [...] allows only two *truth values*, namely *true*[1] and *false*" (Rautenberg, 2009, p.2).

We will use the symbol T for *true* and F for *false*. In contrast to a sentence, a *formula* contains one[2] or more variables, and thus does not have enough meaning by itself to be discernible as true or false. Writing the formula

$$\varphi(x, y, \ldots),$$

[1] A more thorough characterization of the concept of *truth* requires a theory far more fundamental than the one stated in this exposition (see, for instance, Kirkham, 1995).

[2] Until the definition of the numbers 0,1,2 in Section 4, we will use 'one' in the sense of 'a' and 'two' in the sense of 'a [something] and another [something]'

we thus express that x, y, etc. are variables, and $\varphi(x, y, \ldots)$ becomes a sentence (which we then also write as φ) when these variables are replaced by constants.

Example 1.3. Within the context of physics, the formula 'After throwing x in the air, it fell to the ground.' becomes a sentence after replacing x by the specific object *the pebble in my hand.*

We say that $\alpha(\varphi, \psi, \ldots)$ is a *scheme* in case

1. $\alpha(\varphi, \psi, \ldots)$ is a formula with variables φ,ψ, etc. and
2. φ,ψ, etc. are to be replaced by sentences.

Example 1.4. In order for the formula 'After throwing the pebble in the air, φ.' to become a meaningful sentence it is evidently necessary to replace the variable φ by a sentence, such as 'it fell to the ground'.

We will frequently encounter a specific formula $\varphi(x, y, \ldots)$, which becomes a true sentence no matter by which conceivable constants its variables x, y, etc. are replaced. In this connection, we call

$$\forall x\, \forall y, \ldots\ (\varphi(x, y, \ldots)) \tag{1.1}$$

a *universal sentence* in case

1. $\varphi(x, y, \ldots)$ is a formula and
2. $\forall x\, \forall y, \ldots\ (\varphi(x, y, \ldots))$ is a sentence which states that φ is a true sentence for any constants replacing x, y, etc. Here, $\forall$ abbreviates *for any* (alternatively, *for all*), which symbol we call the *universal quantifier*.

When a universal quantifier occurs within a sentence, we also speak of *universal quantification.* We write the universal sentence (1.1) also as

$$\begin{aligned} &\forall x, y, \ldots\ (\varphi(x, y, \ldots)),\\ &\forall x\, (\forall y\, (\cdots (\varphi(x, y, \ldots)) \cdots)). \end{aligned}$$

It may happen that a given formula becomes a true sentence when its variables are replaced by certain constants, and that it may become a false sentence when the variables are replaced by other constants. We say that

$$\exists x\, \exists y, \ldots\ (\varphi(x, y, \ldots)) \tag{1.2}$$

is an *existential sentence* in case

1. $\varphi(x, y, \ldots)$ is a formula and

2. $\exists x\,\exists y, \ldots\,(\varphi(x, y, \ldots))$ is a sentence which states that φ is a true sentence for some constants replacing x, y, etc. Here, $\exists$ abbreviates *for some* (alternatively, *there exists a* or *there is a*), which symbol we refer to as the *existential quantifier*.

When using an existential quantifier within a sentence, we also speak of *existential quantification*. We write the existential sentence (1.2) also as

$$\exists x, y, \ldots\,(\varphi(x, y, \ldots)),$$
$$\exists x\,(\exists y\,(\cdots(\varphi(x, y, \ldots))\cdots)).$$

Variables are usually replaced by constants of a certain type and occurring thus within a certain context, which we will refer to as the *domain of discourse*[3].

It is possible for universal and/or existential quantifiers to occur within a formula, which thus contains one or more variables not being replaced by constants (from the domain of discourse) in connection with the universal/existential quantification. We say that a variable is *bound* in case it occurs in connection with a universal or existential quantifier. Otherwise, we will call the variable *free*.

Example 1.5. Let $\varphi(a, x, y, \ldots)$ be a given formula. Then, the following two formulas have the bound variables x, y and the free variable a.

$$\forall x, y\,(\varphi(a, x, y))$$
$$\forall x\,\exists y\,(\varphi(a, x, y))$$

Once the free variable a is replaced by a constant (from the domain of discourse), these formulas become sentences.

We end this first section with two rules about the application of multiple universal and of multiple existential quantifiers.

Principle 1.2 (Commutativity of universal & of existential quantification). "From the meaning of the universal quantifier it follows that in an expression $\forall x\,\forall y\,(\varphi(x, y))$ the two universal quantifiers may be interchanged without altering the sense of the sentence. This also holds for the existential quantifiers in an expression such as $\exists x\,\exists y\,(\varphi(x, y))$." (Hilbert and Ackermann, 2008, p.60)[4].

[3] We will further characterize this concept after introducing the notion of a *set* in Chapter 2.

[4] In this citation, we omitted the original italic type of the first sentence and replaced the originally stated expressions $(x)(y)A(x, y)$ as well as $(Ex)(Ey)A(x, y)$ by $\forall x\,\forall y\,(\varphi(x, y))$ and $\exists x\,\exists y\,(\varphi(x, y))$, respectively.

When universal and existential quantifiers are applied jointly, their interchange may alter the meaning and the truth value of the sentence.

Example 1.6. To demonstrate the truth of the principle of commutativity with respect to universal quantification, we first consider the two sentences

$$\forall x \, \forall y \, (\varphi(x, y))$$
$$\forall y \, \forall x \, (\varphi(x, y))$$

where the domain of discourse concerning the variable x is given by the list of all planets of the Solar System, where the domain of discourse regarding the variable y is the list of all natural satellites within the Solar System, and where the formula $\varphi(x, y)$ stands for 'x as well as y orbits the Sun'. Evidently, the sentences 'Any planet as well as any moon orbits the Sun' and 'Any moon as well as any planet orbits the Sun' express the same (true) fact.

To verify that the principle of commutativity does not necessarily apply to a combination of universal and existential quantification, let us consider now the two sentences

$$\forall x \, \exists y \, (\psi(x, y))$$
$$\exists y \, \forall x \, (\psi(x, y))$$

where the domain of discourse concerning x is modified to be now the list of all outer planets of the Solar System, and where the formula $\psi(x, y)$ represents 'y orbits x'. The first of the considered sentences may be colloquially written as 'Every outer planet has a moon that revolves it', which is true. The second sentence may be stated as 'There is a moon which revolves all outer planets', which is false.

Note that using the original context of all planets of the Solar System (regarding x) leads to the false sentence 'Every planet has a moon that revolves it'; the second sentence reads then 'There is a moon which revolves all planets', which is also false. Although both sentences have the same truth value, their meanings are qualitatively different.

1.2. Combination of Sentences

In this section we will see how certain connective symbols can be used to obtain a new sentence from one or more given sentences. The following principle lays the foundation for establishing the truth value of a newly assembled sentence.

Principle 1.3 (Two-value logic, Principle of Extensionality). "*Two-valued logic* is based on two foundational principles: the principle of bivalence [...] and the *principle of extensionality*, according to which the truth value of a connected sentence depends only on the truth values of its parts, not on their meaning." (Rautenberg, 2009, p.2)[5].

Before considering mechanisms for combining two (or multiple) sentences, we inspect a natural method for altering the meaning and truth value of a single given sentence.

Definition 1.1 (Negation, not). We form the *negation* of an arbitrary given sentence φ by writing

$$\neg\varphi, \tag{1.3}$$

for which expression we say '*not* φ' or 'it is not true that φ'. In case φ is true, we will take its negation to be a false sentence, and in case φ is false, we consider $\neg\varphi$ as true (thus, the truth value of $\neg\varphi$ depends only on the truth value of φ, in accordance with the principle of extensionality). This definition is encoded concisely in the following table.

φ	$\neg\varphi$
T	F
F	T

The first column of this so-called *truth table* contains all possible truth values that the original sentence φ can attain according to the principle of bivalence, *viz.* T (in the second row) and F (in the third row); the second column then contains the assigned truth values with respect to the negation of the original sentence, according to the two possible cases, *viz.* φ is true (second row) so that $\neg\varphi$ is false, and φ is false (third row) so that $\neg\varphi$ is true.

Example 1.7. Letting φ stand for 'The feather fell to the ground', we could express the negation $\neg\varphi$ verbally as 'It is not true that the feather fell to the ground' or as 'The feather didn't fall to the ground'.

[5] We changed the italic formatting of the original citation.

In the following, we will consider various ways of combining two given sentences φ and ψ. A simple way is to use the word *and* to fuse two sentences.

Definition 1.2 (Conjunction, and). We form the *conjunction* of two given sentences φ and ψ by writing

$$\varphi \wedge \psi, \tag{1.4}$$

for which expression we say 'φ *and* ψ'. We take the conjunction of φ and ψ to be a true sentence only in case both φ is true and ψ is true, as shown in the following truth table.

φ	ψ	$\varphi \wedge \psi$
T	T	T
T	F	F
F	T	F
F	F	F

Notice that a truth value for the new sentence is defined for all possible combinations of truth values that the original sentences can take by themselves.

Example 1.8. We consider, as the domain of discourse, the collection of all objects in my left hand, consisting of a pebble and a feather. Moreover, we let $\varphi(O)$ stand for the formula 'I threw O in the air'. Then, the universal sentence $\forall O\,(\varphi(O))$ may be stated as 'I threw all objects (in my left hand) in the air'. Since there are only two objects in my left hand ('one object and another object'), we may also say that 'I threw the pebble in the air and I threw the feather in the air'. Thus, the preceding universal sentence may also be written in the form of the conjunction $\varphi_p \wedge \varphi_f$ where φ_p stands for the sentence 'I threw the pebble in the air' and where φ_f stands for the sentence 'I threw the feather in the air'.

A third basic method is based on fusing two sentences with the word *or* in the following sense.

Definition 1.3 (Disjunction, or). We form the *disjunction* of two given sentences φ and ψ by writing

$$\varphi \vee \psi, \tag{1.5}$$

for which expression we say 'φ *or* ψ'. This conjunction is defined to be true in case at least one of the original sentences φ and ψ is true, according to the following truth table.

φ	ψ	$\varphi \vee \psi$
T	T	T
T	F	T
F	T	T
F	F	F

The fourth basic method is the logical counterpart of an 'entailment'.

Definition 1.4 (Implication/conditional sentence, if ... then, antecedent/premise/hypothesis, consequent/conclusion). We form an *implication* (alternatively, a *conditional sentence*) based on two given sentences φ and ψ by writing

$$\varphi \Rightarrow \psi, \tag{1.6}$$

for which expression we say '*if* φ, *then* ψ'. This implication is to be considered as false only in in case φ is true and ψ false, as shown by the following truth table.

φ	ψ	$\varphi \Rightarrow \psi$
T	T	T
T	F	F
F	T	T
F	F	T

Here, we call φ the *antecedent* (alternatively, the *premise* or the *hypothesis*) and ψ the *consequent* (alternatively, the *conclusion*).

The truth table for the implication shows that, whenever a given implication $\varphi \Rightarrow \psi$ is true and the antecedent φ happens to be also true, the consequent ψ must be true as well (see the second row, where all three truth values are T). We will refer to this characteristic feature of an implication as the *law of detachment* or as *Modus Ponens*. This law allows us to state a first method for establishing the truth of a sentence (we will encounter further methods in Section 1.3).

Method 1.1 (Inference). In case a given implication $\varphi \Rightarrow \psi$ and its antecedent φ are true, we may in view of the Law of Detachment *infer* (the truth of) ψ from (the truth of) φ. We alternatively say that 'φ implies ψ', or that '(the truth of) ψ follows from (the truth of) φ' (or simply that 'ψ follows to be true').

Example 1.9. The sentence

$$\forall P\,(P \text{ is an outer planet } \Rightarrow \exists S\,(S \text{ orbits } P)),$$

where the universal quantification is with respect to the listed planets within the Solar System and the existential quantification with respect to the listed natural satellites (also within the Solar System) involves an implication and could be phrased as 'If a planet (within the Solar System) is an outer planet, then it has a moon'.

The fifth basic method extends an entailment to form a *bidirectional entailment*.

Definition 1.5 (Equivalence, if and only if/iff, equivalent sentences, necessary and sufficient condition, brackets). We form an *equivalence* of two given sentences φ and ψ by writing

$$\varphi \Leftrightarrow \psi, \tag{1.7}$$

for which we say 'φ *if, and only if* ψ' (or shorter 'φ *iff* ψ'). This implication is defined to be true when the conjunction

$$(\varphi \Rightarrow \psi) \wedge (\psi \Rightarrow \varphi) \tag{1.8}$$

is true, and defined to be false when the preceding conjunction is false. Here, we use *brackets*[6] to indicate which sentences are connected first (here the implications); the unbracketed connection (i.e., the conjunction) is formed last. We then call φ and ψ *equivalent sentences*, and we say that φ is a *necessary and sufficient condition* for ψ and vice versa.

Proposition 1.1. *The equivalence $\varphi \Leftrightarrow \psi$ of two given sentences φ and ψ has the following truth table.*

φ	ψ	$\varphi \Leftrightarrow \psi$
T	T	T
T	F	F
F	T	F
F	F	T

Proof. To construct the truth table given below, we write down all possible combinations of truth values of the sentences φ and ψ (in the first and the second column), determine then row by row for each combination the truth values of the implication $\varphi \Rightarrow \psi$ according to the truth table for an implication (in the third column), similarly the truth values for the second implication $\psi \Rightarrow \varphi$ (in the fourth column), and finally the truth values of the conjunction of the two previously evaluated implications according to the truth table for a conjunction (see the fifth column). Since the equivalence

[6] We will also the bracket symbols [...] and {...}

$\varphi \Leftrightarrow \psi$ was defined to take the same truth values as that conjunction, we immediately obtain the last column, which shows that the proposed truth table applies indeed to the stated equivalence.

φ	ψ	$\varphi \Rightarrow \psi$	$\psi \Rightarrow \varphi$	$(\varphi \Rightarrow \psi) \wedge (\psi \Rightarrow \varphi)$	$\varphi \Leftrightarrow \psi$
T	T	T	T	T	T
T	F	F	T	F	F
F	T	T	F	F	F
F	F	T	T	T	T

$\square$

Note 1.1*.* The truth table in Proposition 1.1 shows that an equivalence turns out to be true in case the original sentences are both true or both false. Moreover, an equivalence is false when one of the original sentences is false and the other true. We also notice that an equivalence is true only in the case that both implications are true; in this case each of the sentences implies the other one.

We are now in a position to define a general *combination of sentences*.

Definition 1.6 (Combination of sentences, logical connectives). We say that α is a *combination of sentences* in case α is a sentence consisting of other given sentences φ, ψ, etc. (including sentences negated by means of $\neg$) that are connected by means of any of the so-called *logical connectives* $\wedge$, $\vee$, $\Rightarrow$, $\Leftrightarrow$ (where brackets are used whenever necessary).

Let us now summarize the symbols previously introduced to aid the formulation of sentences.

Notation 1.1 (Logical symbols)*.* The following symbols are called the *logical symbols*:

- x, y, O, P, S, ... (the variables),
- $\forall$, $\exists$ (the quantifiers),
- $=$ (the equality symbol),
- $\neg$ (the negation symbol),
- $\wedge$, $\vee$, $\Rightarrow$ and $\Leftrightarrow$ (the logical connectives), and
- (...),[...], {...} (the brackets).

1.3. Establishment of True Sentences

In this section we will encounter methods for establishing a newly formed sentence as being true. There are various ways for doing this: For instance, we will frequently 'define', 'assume' or 'prove' a sentence. To bring out the distinction between these 'activities' more clearly, we first characterize different types of sentences.

1.3.1. Types of true sentences

A *definition*, which will always be considered as a true sentence, is characteristically stated in a form such as

$$\text{For any } x \text{ we say that } \varphi(x) \text{ iff } \psi(x). \tag{1.9}$$

Here, x is a variable with respect to a certain domain of discourse (bound via universal quantification), $\varphi(x)$ is a formula which contains besides the bound variable x a new concept (i.e., a new kind of constant in form of a symbol, word or phrase), and $\psi(x)$ is a formula which explains the new concept in terms only of previously introduced concepts/constants.

Example 1.10. Let us take the list of all planets within the Solar System as the domain of discourse, and let us assume that we have previously established (at least) the concepts of a 'planet', the Solar System, and the Asteroid Belt. Then, the following sentence may serve as a (true) definition of an *outer planet*.

$$\begin{aligned}&\text{For any } P \text{ we say that } P \text{ is an outer planet iff}\\ &\quad P \text{ is beyond the Asteroid Belt.}\end{aligned}$$

We could evidently find various other ways of expressing this definition, for instance, 'All planets (of the Solar System) beyond the Asteroid Belt are called outer planets'. Although such formulations may appear to be more concise or elegant, they could obscure the logical structure and thus obstruct their use in subsequent 'logical activities'. We will therefore usually stick to the more formalized structure.

The next kind of true sentence is the *principle* (recall, for instance, the Principle of Bivalence stated in Section 1.1), which we consider as a description of the way that a mathematical method or theory 'works'.

Note 1.2. Recall that the principles of Bivalence and of Extensionality determined the 'working' of a truth table.

Whereas a principle is invariably taken to be a true sentence, an *assumption* is a sentence whose truth is not assigned absolutely, but only temporarily or tentatively within a line of reasoning. By contrast, an *axiom* will be regarded as an 'invariably true assumption'. Thus, an axiom is often quite similar to a principle, but the reason for establishing an axiom is usually less obvious than the reason for adopting a principle.

We will now consider types of sentences whose truth follows necessarily from other facts. To demonstrate the truth of such sentences, we formulate a line of arguments and express it by means of true sentences. We will call such a piece of writing a *proof*. The most relevant results proved throughout this exposition will be called *theorems*. A *lemma* is utilized in a much narrower context than a theorem, usually as a significant stepping stone towards proving a (more widely applied) theorem. Whereas theorems and lemmas are well-known results, regarded to be of such relevance as to deserve their own name (e.g., the *Recursion Theorem*), the *propositions* and *corollaries* represent more ordinary and less standardized stepping stones in developing the mathematical exposition. Whereas the proof of a proposition may be intricate and long (i.e., 'technical'), the proof of a corollary is typically accomplished in a direct, easy-to-follow way by applying a small number of arguments.

1.3.2. Proof techniques for logical connectives and basic sentential laws

In this section we review some standardized procedures for establishing a proof of a given (supposedly true) sentence, which methods we will apply frequently. We first consider combinations of sentences which do not involve quantification.

Definition 1.7 (Tautology, contradiction).

(1) Given an arbitrary combination α of sentences, we say that α is a *tautology* iff α is true irrespective of the truth values that the connected sentences take.

(2) Given an arbitrary combination β of sentences, we say that β is a *contradiction* iff β is false irrespective of the truth values that the connected sentences have.

The following basic technique makes use in particular of the definition of a tautology and of the truth tables regarding the negation and regarding the logical connectives.

Method 1.2 (Proof via truth table). To establish the truth of a given sentence α which is combined of other given sentences φ, ψ, etc. by means of any of the logical connectives, the negation symbol and the brackets, we may show that α is a tautology. To do this, we write down in a systematic way all possible combinations of truth values that the connected sentences φ, ψ, etc. may take according to the Principle of Bivalence. We then determine for each of these combinations of truth values the resulting truth value of α. We may do this successively by considering within one step only one of the negations or logical connectives used to form α, beginning with the innermost bracketed expression(s) and ending with the unbracketed expression.

Example 1.11. Let φ be the sentence 'Today is Monday'. Then, the disjunction

$$\varphi \vee \neg\varphi \tag{1.10}$$

('Today is Monday or today isn't Monday.') should be logically true, irrespective of whether it is actually true or false that today is Monday. Thus, we may anticipate that (1.10) is a law in the form of a tautology. Similarly, the conjunction

$$\varphi \wedge \neg\varphi \tag{1.11}$$

('Today is Monday and today isn't Monday.') should be logically false, again irrespective of whether it is actually true or false that today is Monday. Therefore, we expect (1.11) to be a contradiction. Let us now construct the corresponding truth table(s). In the first column we write down the two possible truth values that φ can have (viz. T and F according to the Principle of Bivalence). In a first step, we use the truth table that characterizes the negation to write down the column of truth values regarding $\neg\varphi$. In a second step, we apply the truth table for the disjunction to determine the truth values of the suspected law (1.10). Since (1.10) turns out to be true for both possible combinations of truth values that φ and $\neg\varphi$ may simultaneously take, (1.10) is a tautology by definition and thus a true sentence. Similarly, we obtain the column of truth values for (1.11), which sentence indeed turns out to be a contradiction.

φ	$\neg\varphi$	$\varphi \vee \neg\varphi$	$\varphi \wedge \neg\varphi$
T	F	T	F
F	T	T	F

Since the law (1.10) we just established will be frequently applied, we state it again as the following theorem.

Theorem 1.2 (Law of the Excluded Middle). *The following disjunction is true for an arbitrary given sentence* φ.

$$\varphi \vee \neg\varphi. \tag{1.12}$$

Note 1.3. The procedure for establishing the truth of the disjunction $\varphi \vee \neg\varphi$ via the preceding truth table simply consists in the demonstration that (at least) one part of the disjunction is true.

We may apply this approach to establish the truth of an arbitrary disjunction $\varphi \vee \psi$.

Method 1.3 (Proof of a disjunction). To prove that the disjunction $\varphi \vee \psi$ of two given sentences φ and ψ is true, we may show that one of the two sentences is true by itself. After this demonstration, we may argue that the disjunction is true, because it is defined to be true when (at least) one of its parts is true.

We now establish further useful facts about tautologies and contradictions, using again the method of truth table.

Theorem 1.3 (Tautology & Contradiction Laws). *The following equivalences are true for an arbitrary given sentence* φ, *an arbitrary tautology* α, *and an arbitrary contradiction* β.

a) **Tautology Law for the conjunction:**

$$\varphi \;\Leftrightarrow\; (\alpha \wedge \varphi). \tag{1.13}$$

b) **Tautology Law for the implication:**

$$\varphi \Leftrightarrow (\alpha \Rightarrow \varphi). \tag{1.14}$$

c) **Contradiction Law:**

$$\varphi \Leftrightarrow (\beta \vee \varphi). \tag{1.15}$$

Proof. Concerning a) – c), we obtain the following truth table, taking account of the definitions of a tautology and of a contradiction, so that the columns of truth values for α and β contains only Ts and Fs, respectively.

φ	α	β	$\alpha \wedge \varphi$	(1.13)	$\alpha \Rightarrow \varphi$	(1.14)	$\beta \vee \varphi$	(1.15)
T	T	F	T	T	T	T	T	T
F	T	F	F	T	F	T	F	T

□

We now demonstrate Method 1.2 by proving the following more intricate theorem.

Theorem 1.4 (Law of the Hypothetical Syllogism). *The following implication is true for arbitrary given sentences α, φ and ψ.*

$$[(\varphi \Rightarrow \alpha) \wedge (\alpha \Rightarrow \psi)] \;\Rightarrow\; [\varphi \Rightarrow \psi]. \tag{1.16}$$

Proof. We form the first three columns of the truth table (given at the end of this paragraph) by writing down all possible combinations of truth values that the three given sentences α, φ and ψ can take. In the fourth and fifth column, we determine the truth values of the innermost logical connections $\varphi \Rightarrow \alpha$ and $\alpha \Rightarrow \psi$, respectively, using the truth table that defines an implication. In the sixth column, we evaluate the conjunction of the previous two implications (using now the truth table regarding the conjunction). At the same level of bracketing is the subsequently evaluated implication $\varphi \Rightarrow \psi$ (second last column). Finally, we write in the last column the truth values of the proposed implication (1.16), based on the various combinations of truth values regarding the previously evaluated antecedent (sixth column) and consequent (seventh column).

φ	α	ψ	$\varphi \Rightarrow \alpha$	$\alpha \Rightarrow \psi$	$(.) \wedge (.)$	$\varphi \Rightarrow \psi$	(1.16)
T	T	T	T	T	T	T	T
T	T	F	T	F	F	F	T
T	F	T	F	T	F	T	T
T	F	F	F	T	F	F	T
F	T	T	T	T	T	T	T
F	T	F	T	F	F	T	T
F	F	T	T	T	T	T	T
F	F	F	T	T	T	T	T

Since the last column with respect to the implication to be proven contains only Ts, we see that this implication is true for any combination of truth values that the connected sentences α, φ and ψ can take. Notice that the truth values of the newly formed connections in Columns 4 – 8 depend only on the truth values of the connected parts and on the kind of connective used, and not on the specific meaning of the connected sentences. Thus, the proof is consistent with the Principle of Extensionality. □

Note 1.4. The preceding truth table hints at a general method for proving a conjunction. Let us observe that the occurrence of the truth value T in the sixth column regarding $(.) \wedge (.)$ stems from the fact that we previously established (within the fourth and the fifth column) the truth value T for both parts $\varphi \Rightarrow \alpha$ and $\alpha \Rightarrow \psi$ of that conjunction.

Method 1.4 (Proof of a conjunction). To prove that a conjunction $\varphi \wedge \psi$ of two given sentences φ and ψ is true, we may show by separate proofs that each of the sentences φ and ψ is true by itself. After this demonstration, we may argue that the conjunction is true, because it is defined to be true precisely when both of its parts are true.

Since an equivalence is defined as a conjunction, this method may be applied for the purpose of establishing the truth of an equivalence.

Method 1.5 (Proof of an equivalence). To prove an equivalence $\varphi \Leftrightarrow \psi$ for given sentences φ and ψ, we may carry out a proof of the conjunction

$$(\varphi \Rightarrow \psi) \wedge (\psi \Rightarrow \varphi),$$

where each of the two parts of this conjunction involves a proof of an implication.

Since implications frequently occur within combinations of sentences, we now describe various ways of proving them. The truth table regarding the proof of the Law of the Hypothetical Syllogism constitutes a suitable starting point for these tasks.

Note 1.5. In the truth table regarding the proof of the Law of the Hypothetical Syllogism, we evaluated four different implications. In view of the definition of an implication, these evaluations can be carried out quite economically. Since an implication is defined to take the truth value T whenever the antecedent is false, we need not care about the truth value of the consequent. Thus, in all four instances in which $(\varphi \Rightarrow \alpha) \wedge (\alpha \Rightarrow \psi)$ takes the value F (within the sixth column), we obtain the truth value T in the corresponding rows for the implication (1.16) (within the last column). In the other four instances in which the antecedent $(\varphi \Rightarrow \alpha) \wedge (\alpha \Rightarrow \psi)$ takes the value T, we actually need to inspect the truth values of the consequent $\varphi \Rightarrow \psi$ in the corresponding rows (within the seventh column). As these values are all T, the implication (1.16) also takes the value T in these instances.

Thus, the definition of an implication gives rise to the following technique for establishing the truth of an implication.

Method 1.6 (Direct proof of an implication). To prove in a direct manner that an implication $\varphi \Rightarrow \psi$ based on two given sentences φ and ψ is true, we may begin by assuming the antecedent φ to be a true (since the implication is automatically true when the antecedent φ is false, so that nothing is to be shown in that case). Then, as an implication is only true in case the consequent is also true, it remains to demonstrate that ψ is true.

Since the Law of the Hypothetical Syllogism states that an implication $\varphi \Rightarrow \psi$ (which we intend to prove) is true precisely when the equivalent sentence $(\varphi \Rightarrow \alpha) \wedge (\alpha \Rightarrow \psi)$ is true, this law may be applied to carry out a direct proof of an implication in two consecutive steps.

Method 1.7 (Direct proof of an implication in steps). To prove in a direct manner that an implication $\varphi \Rightarrow \psi$ based on two given sentences φ and ψ is true, we may carry out a proof of the equivalent conjunction

$$(\varphi \Rightarrow \alpha) \wedge (\alpha \Rightarrow \psi),$$

which then involves two separate proofs of the implications $\varphi \Rightarrow \alpha$ and $\alpha \Rightarrow \psi$.

In situations where the previously established sentences and the antecedent φ of an implication $\varphi \Rightarrow \psi$ to be proven do not provide enough information to demonstrate in the course of a direct proof that the consequent ψ is true, we may introduce a new sentence α jointly with its negation $\neg\alpha$ as additional *case assumptions*. Due to the Law of the Excluded Middle, such two cases are *exhaustive* in the sense that one these cases is necessarily true. The next exercise shows that a given implication may indeed be written equivalently in a form with additional cases and thus justifies the subsequent method.

Exercise 1.1. The following equivalence is true for arbitrary given sentences φ, ψ and α.

$$[\varphi \Rightarrow \psi] \;\Leftrightarrow\; [([\varphi \wedge \alpha] \Rightarrow \psi) \wedge ([\varphi \wedge \neg\alpha] \Rightarrow \psi)]. \tag{1.17}$$

(Hint: Apply a proof via truth table.)

Method 1.8 (Proof of an implication by cases). To prove that an implication $\varphi \Rightarrow \psi$ for given sentences φ and ψ is true, we may establish the equivalent conjunction

$$[(\varphi \wedge \alpha) \Rightarrow \psi] \wedge [(\varphi \wedge \neg\alpha) \Rightarrow \psi].$$

To do this, we assume first $\varphi \wedge \alpha$ (the *first case*) to prove the first implication directly, then $\varphi \wedge \neg\alpha$ (the *second case*) to prove the second implication directly.

We may also consider *cases* to establish the truth of a given sentence ψ which is not in the form of an implication.

Exercise 1.2. Verify the following implication for arbitrary given sentences ψ, α and β.

$$[\alpha \vee \beta] \;\Rightarrow\; [\psi \Leftrightarrow ([\alpha \Rightarrow \psi] \wedge [\beta \Rightarrow \psi])]. \tag{1.18}$$

(Hint: Construct a truth table.)

Since the truth of a given disjunction $\alpha \vee \beta$ implies with (1.18) that a given sentence ψ is equivalent to the conjunction of the implications $\alpha \Rightarrow \psi$ and $\beta \Rightarrow \psi$, we may apply the following method.

Method 1.9 (Proof of a sentence by cases). To show that a given sentence ψ is true, where we have already established the truth of the disjunction $\alpha \vee \beta$ of given sentences α and β, we may carry out a proof of the conjunction

$$(\alpha \Rightarrow \psi) \wedge (\beta \Rightarrow \psi).$$

For this purpose, we assume first α (the *first case*) to prove the first implication directly, then β (the *second case*) to prove the second implication directly.

The following law motivates and justifies an indirect way of proving an implication.

Theorem 1.5 (Law of Contraposition). *The following equivalence is true for arbitrary given sentences φ and ψ.*

$$[\varphi \Rightarrow \psi] \Leftrightarrow [(\neg\psi) \Rightarrow (\neg\varphi)]. \tag{1.19}$$

Proof. We evidently obtain the following truth table by using the truth tables that characterize the negation, the implication, and the equivalence.

φ	ψ	$\neg\psi$	$\neg\varphi$	$(\neg\psi) \Rightarrow (\neg\varphi)$	$\varphi \Rightarrow \psi$	$[\varphi \Rightarrow \psi] \Leftrightarrow [(\neg\psi) \Rightarrow (\neg\varphi)]$
T	T	F	F	T	T	T
T	F	T	F	F	F	T
F	T	F	T	T	T	T
F	F	T	T	T	T	T

The proposed equivalence is seen to be true since it takes the truth value T for all possible combinations of truth values that the connected given sentences φ and ψ can have. $\square$

Method 1.10 (Proof by contraposition). To prove that an implication $\varphi \Rightarrow \psi$ for given sentences φ and ψ is true, we may establish the equivalent implication

$$(\neg\psi) \Rightarrow (\neg\varphi).$$

A second widely applied indirect procedure for establishing implications is prepared by the next exercise.

Exercise 1.3. Show that the following equivalence holds for arbitrary given sentences φ, ψ and β, where β is a contradiction.

$$[\varphi \Rightarrow \psi] \Leftrightarrow [(\varphi \wedge \neg\psi) \Rightarrow \beta]. \tag{1.20}$$

(Hint: Apply a proof via truth table.)

Method 1.11 (Proof of an implication by contradiction). To prove that an implication $\varphi \Rightarrow \psi$ for given sentences φ and ψ is true, we may choose an arbitrary contradiction β and establish the implication

$$(\varphi \wedge \neg\psi) \Rightarrow \beta.$$

Before proceeding with a variant of the proof by contradiction, we establish four more laws.

Theorem 1.6 (Substitution Rules for sentences). *The following sentences are true for arbitrary given sentences φ, ψ and δ.*

a) **Substitution Rule for negations:***:*

$$[\varphi \Leftrightarrow \psi] \;\Rightarrow\; [(\neg\varphi) \Leftrightarrow (\neg\psi)]. \tag{1.21}$$

b) **Substitution Rules for conjunctions:***:*

$$(\varphi \Leftrightarrow \psi) \;\Rightarrow\; ([\delta \wedge \varphi] \Leftrightarrow [\delta \wedge \psi]). \tag{1.22}$$
$$(\varphi \Leftrightarrow \psi) \;\Rightarrow\; ([\varphi \wedge \delta] \Leftrightarrow [\psi \wedge \delta]). \tag{1.23}$$

c) **Substitution Rules for disjunctions:***:*

$$(\varphi \Leftrightarrow \psi) \;\Rightarrow\; ([\delta \vee \varphi] \Leftrightarrow [\delta \vee \psi]). \tag{1.24}$$
$$(\varphi \Leftrightarrow \psi) \;\Rightarrow\; ([\varphi \vee \delta] \Leftrightarrow [\psi \vee \delta]). \tag{1.25}$$

d) **Substitution Rules for implications:***:*

$$(\varphi \Leftrightarrow \delta) \;\Rightarrow\; ([\varphi \Rightarrow \psi] \Leftrightarrow [\delta \Rightarrow \psi]). \tag{1.26}$$
$$(\psi \Leftrightarrow \delta) \;\Rightarrow\; ([\varphi \Rightarrow \psi] \Leftrightarrow [\varphi \Rightarrow \delta]). \tag{1.27}$$

e) **Substitution Rules for equivalences:***:*

$$[(\varphi \Leftrightarrow \delta) \wedge (\psi \Leftrightarrow \delta)] \;\Rightarrow\; [\varphi \Leftrightarrow \psi]. \tag{1.28}$$
$$[(\varphi \Leftrightarrow \delta) \wedge (\delta \Leftrightarrow \psi)] \;\Rightarrow\; [\varphi \Leftrightarrow \psi]. \tag{1.29}$$

Exercise 1.4. Prove the Substitution Rules for sentences.

Note 1.6. The Substitution Rules for sentences show that we may always replace within a given true negation, conjunction, disjunction, implication or equivalence one of the involved sentences by an equivalent sentence to obtain again a true negation, conjunction, disjunction, implication and equivalence, respectively. These rules should be within our grasp, so that we will usually not mention them in applications.

Corollary 1.7. *The following equivalence is true for an arbitrary sentence ψ and an arbitrary tautology α.*

$$\psi \;\Leftrightarrow\; [(\neg\psi) \Rightarrow (\neg\alpha)]. \tag{1.30}$$

Proof. On the one hand, the equivalence $\psi \Leftrightarrow [\alpha \Rightarrow \psi]$ holds according to the Tautology Law for the implication. On the other hand, the equivalence $[\alpha \Rightarrow \psi] \Leftrightarrow [(\neg\psi) \Rightarrow (\neg\alpha)]$ is true because of the Law of Contraposition. Thus, the conjunction

$$(\psi \Leftrightarrow [\alpha \Rightarrow \psi]) \wedge ([\alpha \Rightarrow \psi] \Leftrightarrow [(\neg\psi) \Rightarrow (\neg\alpha)])$$

is also true. Then, this conjunction implies the truth of (1.30) with the Substitution Law for equivalences (1.29). □

The preceding corollary shows that we may demonstrate the truth of a given sentence ψ by carrying out a direct proof of the equivalent implication $(\neg\psi) \Rightarrow (\neg\alpha)$, where α is a sentence known to be true.

Method 1.12 (Proof of a sentence by contradiction). To prove that a given sentence ψ is true, we may assume $\neg\psi$ to be true, choose an arbitrary tautology α (i.e., an already established true sentence), and show then that $\neg\alpha$ is also true.

In the remainder of the current Section 1.3.2, we state further necessary laws, which we may all be proved by means of truth tables. To begin with, we see that an implication may be explained solely by means of a negation and a disjunction.

Theorem 1.8 (Conditional Laws). *The following equivalences are true for arbitrary given sentences φ and ψ.*

$$[\varphi \Rightarrow \psi] \;\Leftrightarrow\; [(\neg\varphi) \vee \psi]. \tag{1.31}$$
$$[\neg(\varphi \Rightarrow \psi)] \;\Leftrightarrow\; [\varphi \wedge (\neg\psi)]. \tag{1.32}$$

Proof. Regarding (1.31), we evidently obtain the following truth table by using the truth tables that characterize the negation, the implication, and the equivalence.

φ	ψ	$\neg\varphi$	$(\neg\varphi) \vee \psi$	$\varphi \Rightarrow \psi$	$[\varphi \Rightarrow \psi] \Leftrightarrow [(\neg\varphi) \vee \psi]$
T	T	F	T	T	T
T	F	F	F	F	T
F	T	T	T	T	T
F	F	T	T	T	T

The proposed equivalence is seen to be true since it takes the truth value T for all possible combinations of truth values that the connected given sentences φ and ψ can have. $\square$

Exercise 1.5. Prove (1.32) via truth table.

Combining a sentence with itself via conjunction or disjunction, we see that one of the two is redundant.

Theorem 1.9 (Idempotent Laws for sentences). *The following equivalences are true for an arbitrary given sentence φ.*

a) **Idempotent Law for the conjunction:**

$$(\varphi \wedge \varphi) \ \Leftrightarrow \ \varphi. \tag{1.33}$$

b) **Idempotent Law for the disjunction:**

$$(\varphi \vee \varphi) \ \Leftrightarrow \ \varphi. \tag{1.34}$$

Proof. Since the given sentence φ is combined with itself, we duplicate for greater clarity the column of truth values that φ may take when constructing the truth table.

φ	φ	$\varphi \wedge \varphi$	$(\varphi \wedge \varphi) \Leftrightarrow \varphi$	$\varphi \vee \varphi$	$(\varphi \vee \varphi) \Leftrightarrow \varphi$
T	T	T	T	T	T
F	F	F	T	F	T

The proposed equivalences are true since they invariably take the truth value T for both possible combinations of truth values that φ may take. $\square$

We obtain an equivalent version of a sentence by negating it twice.

Theorem 1.10 (Double Negation Law). *The following equivalence holds for an arbitrary given sentence φ.*

$$\varphi \ \Leftrightarrow \ \neg(\neg\varphi). \tag{1.35}$$

Exercise 1.6. Prove the Double Negation Law via truth table.

The following commutative laws show that, in case two sentences are combined via conjunction, disjunction or equivalence, we may interchange the sentences without altering the truth value of the combination.

Theorem 1.11 (Commutative Laws for sentences). *The following equivalences are true for arbitrary given sentences φ and ψ.*

a) **Commutative Law for the conjunction:**

$$(\varphi \wedge \psi) \Leftrightarrow (\psi \wedge \varphi). \tag{1.36}$$

b) **Commutative Law for the disjunction:**

$$(\varphi \vee \psi) \;\Leftrightarrow\; (\psi \vee \varphi). \tag{1.37}$$

c) **Commutative Law for the equivalence:**

$$(\varphi \Leftrightarrow \psi) \;\Leftrightarrow\; (\psi \Leftrightarrow \varphi). \tag{1.38}$$

Exercise 1.7. Verify the Commutative Laws for sentences.

The subsequent associative laws indicate that it is irrelevant in which order we combine three sentences via conjunctions/disjunctions.

Theorem 1.12 (Associative Laws for sentences). *The following equivalences are true for arbitrary given sentences φ, ψ and ϑ.*

a) **Associative Law for the conjunction:**

$$[(\varphi \wedge \psi) \wedge \vartheta] \;\Leftrightarrow\; [\varphi \wedge (\psi \wedge \vartheta)]. \tag{1.39}$$

b) **Associative Law for the disjunction:**

$$[(\varphi \vee \psi) \vee \vartheta] \;\Leftrightarrow\; [\varphi \vee (\psi \vee \vartheta)]. \tag{1.40}$$

Exercise 1.8. Prove the Associative Laws for sentences.

Notation 1.2. The Associative Laws for sentences show that the truth value of the conjunction or disjunction of three sentences does not depend on the position of the brackets (.). We will therefore usually write for the left-hand and the right-hand side of (1.39) and of (1.40)

$$\varphi \wedge \psi \wedge \vartheta, \tag{1.41}$$

$$\varphi \vee \psi \vee \vartheta. \tag{1.42}$$

This notation allows for a straightforward modification of the method for proving a sentence by cases.

Exercise 1.9. Verify the following implication for arbitrary given sentences ψ, α, β and γ.

$$[\alpha \vee \beta \vee \gamma] \;\Rightarrow\; [\psi \Leftrightarrow ([\alpha \Rightarrow \psi] \wedge [\beta \Rightarrow \psi] \wedge [\gamma \Rightarrow \psi])]. \tag{1.43}$$

Method 1.13 (Proof by three cases). To show that a given sentence ψ is true, where we have already established the truth of the disjunction $\alpha \vee \beta \vee \gamma$ of given sentences α, β and γ, we may prove that each of the three parts of the multiple conjunction

$$(\alpha \Rightarrow \psi) \wedge (\beta \Rightarrow \psi) \wedge (\gamma \Rightarrow \psi)$$

is true. For this purpose, we assume first α (the *first case*) to prove the first implication directly, then β (the *second case*) to prove the second implication directly, and finally γ (the *third case*) to prove the third implication directly.

There are various useful distributive laws regarding the formation of sentences, which involve two different logical connectives.

Theorem 1.13 (Distributive Laws for sentences). *The following equivalences are true for arbitrary given sentences α, β and φ.*

a) **Distributivity of the conjunction over the disjunction:**

$$[\varphi \wedge (\alpha \vee \beta)] \;\Leftrightarrow\; [(\varphi \wedge \alpha) \vee (\varphi \wedge \beta)]. \tag{1.44}$$

b) **Distributivity of the disjunction over the conjunction:**

$$[\varphi \vee (\alpha \wedge \beta)] \;\Leftrightarrow\; [(\varphi \vee \alpha) \wedge (\varphi \vee \beta)]. \tag{1.45}$$

c) **Distributivity of the implication over the conjunction:**

$$[\varphi \Rightarrow (\alpha \wedge \beta)] \;\Leftrightarrow\; [(\varphi \Rightarrow \alpha) \wedge (\varphi \Rightarrow \beta)]. \tag{1.46}$$

d) **Distributivity of the implication over the disjunction:**

$$[\varphi \Rightarrow (\alpha \vee \beta)] \;\Leftrightarrow\; [(\varphi \Rightarrow \alpha) \vee (\varphi \Rightarrow \beta)]. \tag{1.47}$$

Exercise 1.10. Establish the Distributive Laws for sentences.

Proof. □

The following frequently applied laws do not strictly fit into the preceding scheme of distributivity, which we therefore state separately.

Exercise 1.11. Establish the following equivalences for arbitrary given sentences α, β and φ.

$$[(\alpha \wedge \beta) \Rightarrow \varphi] \;\Leftrightarrow\; [(\alpha \Rightarrow \varphi) \vee (\beta \Rightarrow \varphi)]. \tag{1.48}$$

$$\Leftrightarrow\; [\alpha \Rightarrow (\beta \Rightarrow \varphi)]. \tag{1.49}$$

$$[(\alpha \vee \beta) \Rightarrow \varphi] \;\Leftrightarrow\; [(\alpha \Rightarrow \varphi) \wedge (\beta \Rightarrow \varphi)]. \tag{1.50}$$

De Morgan's laws show that negating a conjunction yields a disjunction and vice versa.

Theorem 1.14 (De Morgan's Laws for sentences). *The following equivalences are true for arbitrary given sentences φ and ψ.*

a) **De Morgan's Law for the conjunction:**

$$[\neg(\varphi \wedge \psi)] \ \Leftrightarrow \ [(\neg\varphi) \vee (\neg\psi)]. \tag{1.51}$$

b) **De Morgan's Law for the disjunction:**

$$[\neg(\varphi \vee \psi)] \ \Leftrightarrow \ [(\neg\varphi) \wedge (\neg\psi)]. \tag{1.52}$$

Exercise 1.12. Prove De Morgan's Laws for sentences via truth table.

1.3.3. Basic laws for existential and universal quantification

Theorem 1.15 (Quantifier Negation Laws). *The following equivalences are true for an arbitrary given formula $\varphi(y)$.*

a) **Negation Law for universal sentences:**

$$\neg\forall y\,(\varphi(y)) \ \Leftrightarrow \ \exists y\,(\neg\varphi(y)). \tag{1.53}$$

b) **Negation Law for existential sentences:**

$$\neg\exists y\,(\varphi(y)) \ \Leftrightarrow \ \forall y\,(\neg\varphi(y)). \tag{1.54}$$

Proof. Concerning a), we notice that the negation $\neg\forall y\,(\varphi(y))$ means that

- it is not true that $\varphi(y)$ holds for all y, that is,
- there is a y for which $\varphi(y)$ does not hold, that is,
- there is a y for which it is not true that $\varphi(y)$,

which means $\exists y\,(\neg\varphi(y))$. Since all of these sentences have the same meaning, they are either all false or all true. Thus, the two sentences $\neg\forall y\,(\varphi(y))$ and $\exists y\,(\neg\varphi(y))$ either both take the truth value T or both the truth value F, so that they are indeed equivalent.

Concerning b), the negation $\neg\exists y\,(\varphi(y))$ means that

- it is not true that $\varphi(y)$ holds for some (i.e., at least one) y, that is,

- $\varphi(y)$ does not hold for any y, that is,
- for any y it is not true that $\varphi(y)$,

which means $\forall y\,(\neg\varphi(y))$. Because all of these sentences mean the same thing and thus share the same truth value, we have in particular that the two sentences $\neg\exists y\,(\varphi(y))$ and $\forall y\,(\neg\varphi(y))$ are equivalent. □

Corollary 1.16. *The following equivalences hold for an arbitrary formula* $\varphi(x, y)$*.*

$$\neg\forall x, y\,(\varphi(x, y)) \;\Leftrightarrow\; \exists x, y\,(\neg\varphi(x, y)), \tag{1.55}$$

$$\neg\exists x, y\,(\varphi(x, y)) \;\Leftrightarrow\; \forall x, y\,(\neg\varphi(x, y)). \tag{1.56}$$

Proof. We obtain the following equivalences immediately with the notations for universal/existential sentences and with the Quantifier Negation Laws.

$$\begin{aligned}
\neg\forall x, y\,(\varphi(x, y)) &\Leftrightarrow \neg\forall x\,(\forall y\,(\varphi(x, y)))\\
&\Leftrightarrow \exists x\,(\neg\forall y\,(\varphi(x, y)))\\
&\Leftrightarrow \exists x\,(\exists y\,(\neg\varphi(x, y)))\\
&\Leftrightarrow \exists x, y\,(\neg\varphi(x, y)),
\end{aligned}$$

$$\begin{aligned}
\neg\exists x, y\,(\varphi(x, y)) &\Leftrightarrow \neg\exists x\,(\exists y\,(\varphi(x, y)))\\
&\Leftrightarrow \forall x\,(\neg\exists y\,(\varphi(x, y)))\\
&\Leftrightarrow \forall x\,(\forall y\,(\neg\varphi(x, y)))\\
&\Leftrightarrow \forall x, y\,(\neg\varphi(x, y)).
\end{aligned}$$

The proposed equivalences follow then to be true with the Substitution Rule for equivalences (1.29). □

We were able to reveal the truth of the previous two relationships (1.53) and (1.54) between universal and existential sentences by analyzing the meanings of universal and existential quantification in connection with negation. We now formulate a method for establishing the truth of a universal sentence based on the following logical connection between the words 'for any' and 'for an arbitrary'. The idea will be to demonstrate that a given formula $\varphi(x)$ becomes a true sentence no matter which constant we take from the universe to replace the variable x. The practical approach to doing this will be to take an arbitrary constant $\bar{x}$, or in other words, to 'let $\bar{x}$ be arbitrary', and to prove then the sentence $\varphi(\bar{x})$. Having accomplished this task, $\varphi(\bar{x})$ thus holds for an arbitrary constant $\bar{x}$, which means that we may just as well take any of the other constants to obtain that true sentence. We therefore infer from the truth of $\varphi(\bar{x})$ for the arbitrary $\bar{x}$ the truth of $\varphi(x)$ for any x.

Method 1.14 (Proof of a universal sentence). To prove that a universal sentence $\forall x\,(\varphi(x))$ is true, we take an arbitrary constant $\bar{x}$ from the domain of discourse and show that $\varphi(\bar{x})$ is a true sentence in that particular instance. Then, since $\varphi(\bar{x})$ is true for an arbitrary $\bar{x}$, we may conclude that $\varphi(x)$ holds for any x, i.e. that the universal sentence $\forall x\,(\varphi(x))$ is true.

The idea for proving an existential sentence is less intricate.

Method 1.15 (Proof of an existential sentence). To prove that an existential sentence $\exists x\,(\varphi(x))$ is true, we seek within the given domain of discourse a particular constant, say $\bar{x}$, for which we can show that $\varphi(\bar{x})$ is true. After this demonstration, we may argue that $\varphi(x)$ is true for some x.

The proofs of the following sentences demonstrate the application of some of the previously established proof techniques.

Theorem 1.17 (Neutrality Laws for quantification). *The following sentences are true for an arbitrary formula $\psi(y)$.*

a) *The conjunction involving an arbitrary given sentence φ is neutral with respect to existential quantification in the sense that*

$$[\varphi \wedge \exists y\,(\psi(y))] \;\Leftrightarrow\; \exists y\,(\varphi \wedge \psi(y)), \tag{1.57}$$

$$[\exists y\,(\psi(y)) \wedge \varphi] \;\Leftrightarrow\; \exists y\,(\psi(y) \wedge \varphi). \tag{1.58}$$

b) *The disjunction involving an arbitrary given sentence φ is neutral with respect to existential quantification in the sense that*

$$[\varphi \vee \exists y\,(\psi(y))] \;\Leftrightarrow\; \exists y\,(\varphi \vee \psi(y)), \tag{1.59}$$

$$[\exists y\,(\psi(y)) \vee \varphi] \;\Leftrightarrow\; \exists y\,(\psi(y) \vee \varphi). \tag{1.60}$$

c) *The conjunction involving an arbitrary given sentence φ is neutral with respect to universal quantification in the sense that*

$$[\varphi \wedge \forall y\,(\psi(y))] \;\Leftrightarrow\; \forall y\,(\varphi \wedge \psi(y)), \tag{1.61}$$

$$[\forall y\,(\psi(y)) \wedge \varphi] \;\Leftrightarrow\; \forall y\,(\psi(y) \wedge \varphi). \tag{1.62}$$

d) *The disjunction involving an arbitrary given sentence φ is neutral with respect to universal quantification in the sense that*

$$[\varphi \vee \forall y\,(\psi(y))] \;\Leftrightarrow\; \forall y\,(\varphi \vee \psi(y)), \tag{1.63}$$

$$[\forall y\,(\psi(y)) \vee \varphi] \;\Leftrightarrow\; \forall y\,(\psi(y) \vee \varphi) \tag{1.64}$$

e) The implication involving an arbitrary given antecedent φ is neutral with respect to universal quantification in the sense that

$$[\varphi \Rightarrow \forall y\,(\psi(y))] \;\Leftrightarrow\; \forall y\,(\varphi \Rightarrow \psi(y)). \tag{1.65}$$

Proof. Concerning a), we prove the equivalence (1.57) with two direct proofs of an implication, the first of these in combination with a proof of an existential sentence, the second in combination with a proof of a conjunction. To prove the first implication ('$\Rightarrow$') directly, we assume that

$$\varphi \,\wedge\, \exists y(\psi(y)) \tag{1.66}$$

is true. On the one hand, the second part $\exists y(\psi(y))$ of this conjunction is thus true in particular, which means that there exists some y within the domain of discourse, say $\bar{y}$, such that $\psi(\bar{y})$ holds. On the other hand, the conjunction (1.66) implies in particular the truth of φ, so that φ and $\psi(\bar{y})$ are both true. Thus, the conjunction $\varphi \wedge \psi(\bar{y})$ holds, which shows that $\varphi \wedge \psi(y)$ is true for some y. This finding establishes the truth of the existential sentence $\exists y(\varphi \wedge \psi(y))$, so that the proof of the first implication is complete.

To prove the second implication ('$\Leftarrow$') directly, we now assume the existential sentence $\exists y(\varphi \wedge \psi(y))$, which means that there is some y, say $\bar{y}$, such that

$$\varphi \,\wedge\, \psi(\bar{y}) \tag{1.67}$$

is true. This conjunction implies, on the one hand, especially $\psi(\bar{y})$, which shows that $\psi(y)$ holds for some y, so that the existential sentence $\exists y(\psi(y))$ is true. On the other hand, the conjunction (1.67) implies especially φ. Thus, φ and $\exists y(\psi(y))$ are both true, so that the conjunction $\varphi \wedge \exists y(\psi(y))$ holds, which proves the second implication. Consequently, the equivalence (1.57) is true.

Concerning b), we prove the first implication ('$\Rightarrow$') of (1.59) directly, assuming

$$\varphi \,\vee\, \exists y(\psi(y)) \tag{1.68}$$

to be true. In case the first part φ of this disjunction is true, we replace the variable y in $\psi(y)$ by an arbitrary $\bar{y}$ from the domain of discourse and form the disjunction $\varphi \vee \psi(\bar{y})$; since the first part of this disjunction is true, the disjunction itself is also true, irrespective of the truth value of $\psi(\bar{y})$. In case the second part $\exists y(\psi(y))$ of the disjunction (1.68) is true, there is some y, say $\bar{y}$, such that $\psi(\bar{y})$ holds; then, the disjunction $\varphi \vee \psi(\bar{y})$ is also true, irrespective of the truth value of φ. Thus, the disjunction $\varphi \vee \psi(\bar{y})$ is true in any case, and the truth of this disjunction shows that there is some

y for which $\varphi \vee \psi(y)$ becomes true. This means that $\exists y(\varphi \vee \psi(y))$ holds, so that the proof of the first part of the equivalence (1.59) is complete.

To prove the second part ('$\Leftarrow$') directly, we now assume the existential sentence $\exists y(\varphi \vee \psi(y))$ to be true, so that there is some y, say $\bar{y}$, satisfying

$$\varphi \ \vee \ \psi(\bar{y}). \tag{1.69}$$

If the first part φ of this disjunction is true, then the disjunction $\varphi \vee \exists y(\psi(y))$ also holds (irrespective of the truth value of $\exists y(\psi(y))$). If the second part $\psi(\bar{y})$ of the disjunction (1.69) is true, then there evidently is some y such that $\psi(y)$ holds, which means that the existential sentence $\exists y(\psi(y))$ is true. Then, the disjunction $\varphi \vee \exists y(\psi(y))$ holds again (irrespective of the truth value of φ), so that the proof of the second implication is complete. Thus, the equivalence (1.59) is true.

Concerning c), we prove the first part ('$\Rightarrow$') of the equivalence (1.61) directly, assuming

$$\varphi \ \wedge \ \forall y\,(\psi(y)) \tag{1.70}$$

to hold. We now take an arbitrary $\bar{y}$. As the preceding conjunction implies especially $\forall y\,(\psi(y))$, we have that $\psi(\bar{y})$ is true in particular. Moreover, the conjunction (1.70) implies especially also the truth of φ. Thus, φ and $\psi(\bar{y})$ are both true, so that the conjunction $\varphi \wedge \psi(\bar{y})$ holds (for the arbitrary $\bar{y}$). We may therefore conclude that the conjunction $\varphi \wedge \psi(y)$ is true for any y, which means $\forall y(\varphi \wedge \psi(y))$. Thus, the first part of the equivalence (1.61) holds.

Regarding the second part ('$\Leftarrow$'), we now assume $\forall y(\varphi \wedge \psi(y))$ to be true. Taking an arbitrary constant $\bar{y}$ from the domain of discourse, we then have that $\varphi \wedge \psi(\bar{y})$ is true in particular, which conjunction in turn implies especially the truth of φ. Next, we establish the universal sentence $\forall y(\psi(y))$ and let $\bar{\bar{y}}$ be arbitrary. In view of the assumed universal sentence, we see that $\varphi \wedge \psi(\bar{\bar{y}})$ is then true in particular, and that this conjunction now further implies the truth especially of $\psi(\bar{\bar{y}})$. Since $\bar{\bar{y}}$ is arbitrary, we may therefore conclude that the universal sentence $\forall y(\psi(y))$ is true, besides φ. Thus, the conjunction $\varphi \wedge \forall y(\psi(y))$ holds, which proves the implication '$\Leftarrow$', so that the proof of the first equivalence in c) is complete.

Concerning d), we prove the first part ('$\Rightarrow$') of the equivalence (1.63) directly, making the assumption that

$$\varphi \ \vee \ \forall y\,(\psi(y)) \tag{1.71}$$

is true. To prove the universal sentence on the right-hand side of the equivalence (1.63), we let $\bar{y}$ be arbitrary within the domain of discourse. On the one hand, in case the first part φ of the preceding disjunction is true, the disjunction $\varphi \vee \psi(\bar{y})$ is then also true (irrespective of the truth value of $\psi(\bar{y})$). On the other hand, in case the second part $\forall y(\psi(y))$ of the disjunction (1.71) is true, then $\psi(\bar{y})$ is in particular true for the arbitrarily selected $\bar{y}$, so that the disjunction $\varphi \vee \psi(\bar{y})$ is also true (irrespective of the truth value of φ). We thus showed that $\varphi \vee \forall y(\psi(y))$ implies $\varphi \vee \psi(\bar{y})$ for an arbitrary $\bar{y}$, so that we may conclude that this disjunction is true for any y. Thus, $\forall y(\varphi \vee \psi(y))$ holds, completing the proof of the first implication.

We prove the second part ('$\Leftarrow$') of the equivalence by contraposition, i.e. we prove (directly) the implication

$$\neg[\varphi \vee \forall y\,(\psi(y))] \Rightarrow \neg\forall y\,(\varphi \vee \psi(y)).$$

For this purpose we assume that the antecedent $\neg[\varphi \vee \forall y(\psi(y))]$ is true, which then implies the conjunction $\neg\varphi \wedge \neg\forall y(\psi(y))$ with De Morgan's Law for sentences (1.52), and therefore especially $\neg\varphi$ as well as $\neg\forall y(\psi(y))$. The latter negation now further implies $\exists y(\neg\psi(y))$ with the Quantifier Negation Law (1.53). Since $\neg\varphi$ is also true, the conjunction $\neg\varphi \wedge \exists y(\neg\psi(y))$ holds. This in turn implies $\exists y(\neg\varphi \wedge \neg\psi(y))$ with a), so that there exists some y, say $\bar{y}$, such that $\neg\varphi \wedge \neg\psi(\bar{y})$ holds. Applying now again De Morgan's Law for sentences (1.52), we obtain the true negation $\neg[\varphi \vee \psi(\bar{y})]$, which shows that $\neg[\varphi \vee \psi(y)]$ is true for some y. This means $\exists y(\neg[\varphi \vee \psi(y)])$, which implies the desired consequent $\neg\forall y(\varphi \vee \psi(y))$ with the Quantifier Negation Law (1.53). This completes the proof of the second part of the proposed equivalence, which is therefore true.

Concerning e), we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $\varphi \Rightarrow \forall y(\psi(y))$ to be true, which implication implies with the Conditional Law (1.31) the true disjunction $\neg\varphi \vee \forall y(\psi(y))$, which in turn implies $\forall y(\neg\varphi \vee \psi(y))$ with d). To establish the right-hand side $\forall y(\varphi \Rightarrow \psi(y))$ of the equivalence (1.65), we let $\bar{y}$ be arbitrary, so that the previously obtained universal sentence gives in particular the true sentence $\neg\varphi \vee \psi(\bar{y})$, which implies $\varphi \Rightarrow \psi(\bar{y})$ again with the Conditional Law (1.31). Since $\bar{y}$ is arbitrary, we may therefore conclude that the universal sentence $\forall y(\varphi \Rightarrow \psi(y))$ holds, which completes the proof of the first part of the proposed equivalence e).

To prove the second part ('$\Leftarrow$'), we now assume the universal sentence $\forall y(\varphi \Rightarrow \psi(y))$ to be true. To show that this implies the implication $\varphi \Rightarrow \forall y(\psi(y))$, we assume that φ holds and demonstrate that $\forall y(\psi(y))$ follows to be true. For this purpose, we take an arbitrary $\bar{y}$, so that the assumed universal sentence yields in particular $\varphi \Rightarrow \psi(\bar{y})$. Since φ is by assumption true, this implies $\psi(\bar{y})$ with the preceding implication. As $\bar{y}$ was arbitrary, we may therefore conclude that the universal sentence $\forall y(\psi(y))$ is indeed true. This in turn proves the implication $\varphi \Rightarrow \forall y(\psi(y))$ and thus the second part of the equivalence e). Consequently, (1.65) is also true. $\square$

Exercise 1.13. Prove (1.58), (1.60), (1.62), and (1.64).
(Hint: Proceed in analogy to the proofs of (1.57), (1.59), (1.61) and (1.63).)

Strict neutrality of the implication with respect to universal quantification does not hold in case the sentence φ appears as the consequent.

Exercise 1.14. Verify the following sentences for an arbitrary sentence φ and an arbitrary formula $\psi(y)$.

$$[\exists y\,(\psi(y)) \Rightarrow \varphi] \;\Leftrightarrow\; \forall y\,(\psi(y) \Rightarrow \varphi). \tag{1.72}$$

$$\exists y\,(\psi(y)) \;\Rightarrow\; [\varphi \Leftrightarrow \forall y\,(\psi(y) \Rightarrow \varphi)]. \tag{1.73}$$

(Hint: regarding (1.72), prove both parts of the equivalence directly. Prove the implication (1.73) and both parts of the equivalence therein directly.)

Theorem 1.18 (Distributive Laws for quantification). *The following sentences are true for arbitrary formulas $\varphi(y)$ and $\psi(y)$.*

a) Universal quantification distributes over the conjunction in the sense that

$$\forall y\,(\varphi(y) \,\wedge\, \psi(y)) \;\Leftrightarrow\; [\forall y\,(\varphi(y)) \,\wedge\, \forall y\,(\psi(y))]. \tag{1.74}$$

b) Existential quantification distributes over the disjunction in the sense that

$$\exists y\,(\varphi(y) \,\vee\, \psi(y)) \;\Leftrightarrow\; [\exists y\,(\varphi(y)) \,\vee\, \exists y\,(\psi(y))]. \tag{1.75}$$

Proof. Regarding a), we carry out a proof of an equivalence by proving the two implications directly, the first in combination with a proof of a conjunction, the second in combination with a proof of a universal sentence. To prove the first implication ('$\Rightarrow$'), we make the assumption that $\forall y(\varphi(y) \wedge \psi(y))$ is true. To prove the universal sentence on the right-hand side of the equivalence (1.74), we let $\bar{y}$ be arbitrary. Because of the assumed universal sentence,

$$\varphi(\bar{y}) \wedge \psi(\bar{y}) \tag{1.76}$$

is then in particular true. This conjunction implies, on the one hand, that $\varphi(\bar{y})$ is especially true (for the arbitrary $\bar{y}$), so that we may conclude that the universal sentence $\forall y(\varphi(y))$ holds. On the other hand, the conjunction (1.76) implies especially that $\psi(\bar{y})$ is true (for the arbitrary $\bar{y}$), from which we may infer that the universal sentence $\forall y(\psi(y))$ holds as well. Since $\forall y(\varphi(y))$ and $\forall y(\psi(y))$ are both true, the conjunction $\forall y(\varphi(y)) \wedge \forall y(\psi(y))$ holds, which proves the first part of the proposed equivalence.

To prove the second implication ('$\Leftarrow$') directly, we now assume that $\forall y(\varphi(y)) \wedge \forall y(\psi(y))$ is true, which means that $\forall y\,(\varphi(y))$ and $\forall y\,(\psi(y))$ are both true. To prove the universal sentence on the left-hand side of the equivalence (1.74), we take an arbitrary $\bar{y}$. In view of the previous two universal sentences, we then see that $\varphi(\bar{y})$ and $\psi(\bar{y})$ are both true in particular, which means that the conjunction $\varphi(\bar{y}) \wedge \psi(\bar{y})$ holds. As $\bar{y}$ was arbitrary, we therefore conclude that $\forall y(\varphi(y) \wedge \psi(y))$ is true, which proves the second part of the equivalence. As both implications are true, the proposed equivalence a) holds.

Concerning b), we first prove ('$\Rightarrow$') directly, by assuming $\exists y\,(\varphi(y) \vee \psi(y))$, which means that there is some y, say $\bar{y}$, such that

$$\varphi(\bar{y}) \;\vee\; \psi(\bar{y}) \tag{1.77}$$

is true. If, on the one hand, $\varphi(\bar{y})$ is true, we have that $\varphi(y)$ holds for some y, which means that $\exists y(\varphi(y))$ holds; then, the disjunction $\exists y(\varphi(y)) \vee \exists y(\psi(y))$ is also true, irrespective of the truth value of $\exists y(\psi(y))$. If, on the other hand, the second part $\psi(\bar{y})$ of the disjunction (1.77) is true, then $\psi(y)$ holds for some y, which means that $\exists y(\psi(y))$ holds; consequently, the disjunction $\exists y(\varphi(y)) \vee \exists y(\psi(y))$ is true as well, irrespective of the truth value of $\exists y(\psi(y))$. Thus, the first part of the equivalence holds.

To prove ('$\Leftarrow$'), we now assume

$$\exists y(\varphi(y)) \vee \exists y(\psi(y)). \tag{1.78}$$

On the one hand, if $\exists y(\varphi(y))$ is true, this means that there is some y, say $\bar{y}$, such that $\varphi(\bar{y})$ holds, which gives the true disjunction $\varphi(\bar{y}) \vee \psi(\bar{y})$ (irrespective of the truth value of $\psi(\bar{y})$); this shows that $\varphi(y) \vee \psi(y)$ holds for some y, so that $\exists y(\varphi(y) \vee \psi(y))$ holds. On the other hand, if the second part $\exists y(\psi(y))$ of the disjunction in (1.78) is true, there is some y, say $\bar{y}$, such that $\psi(\bar{y})$ holds, which yields again the true disjunction $\varphi(\bar{y}) \vee \psi(\bar{y})$ (irrespective of the truth value of $\varphi(\bar{y})$); as before, this means that $\exists y(\varphi(y) \vee \psi(y))$ is true, so that we proved the second implication and thus the equivalence. $\square$

Note 1.7. We see in (1.74) that $\forall$ is in a certain sense 'compatible' with $\wedge$, and similarly in (1.75) that $\exists$ is compatible with $\vee$. These kinds of compatibility are also reflected by the fact that, on the one hand, $\forall y(\varphi(y))$ means that $\varphi(y)$ is true for a constant $\bar{a}$ of the domain of discourse, and is true also for another constant $\bar{b}$, and for another $\bar{c}$, etc., so that $\forall$ connects all the true sentences $\varphi(\bar{a})$, $\varphi(\bar{b})$, $\varphi(\bar{c})$, etc., with conjunctions.

Similarly, $\exists y(\varphi(y))$ means that $\varphi(y)$ may be found to be true after replacing the variable y by some particular constant $\bar{a}$, or $\bar{b}$, or $\bar{c}$, etc., so that

$\exists$ connects the possibly true sentences $\varphi(\bar{a})$, $\varphi(\bar{b})$, $\varphi(\bar{c})$, etc., by means of disjunctions.

Thus, we consider the equivalences

$$\forall y\,(\varphi(y)) \;\Leftrightarrow\; [\varphi(\bar{a}) \,\wedge\, \varphi(\bar{b}) \,\wedge\, \varphi(\bar{c}) \,\wedge\, \cdots], \tag{1.79}$$

$$\exists y\,(\varphi(y)) \;\Leftrightarrow\; [\varphi(\bar{a}) \,\vee\, \varphi(\bar{b}) \,\vee\, \varphi(\bar{c}) \,\vee\, \cdots] \tag{1.80}$$

to be true.

Theorem 1.19 (Negation Law for existential conjunctions & for universal implications). *The following equivalences are true for arbitrary formulas $\varphi(y)$ and $\vartheta(y)$.*

a) **Negation Law for existential conjunctions:**

$$\neg\exists y\,(\varphi(y) \,\wedge\, \vartheta(y)) \;\Leftrightarrow\; \forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y)). \tag{1.81}$$

b) **Negation Law for universal implications:**

$$\neg\forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y)) \;\Leftrightarrow\; \exists y\,(\varphi(y) \,\wedge\, \vartheta(y)). \tag{1.82}$$

Proof. Concerning (1.81), we first observe that $\neg\exists y(\varphi(y) \wedge \vartheta(y))$ is equivalent to

$$\forall y\,(\neg[\varphi(y) \,\wedge\, \vartheta(y)]) \tag{1.83}$$

because of the Quantifier Negation Law (1.54). We now prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $\neg\exists y(\varphi(y) \wedge \vartheta(y))$ to be true, which then implies the truth of (1.83). To establish the universal sentence

$$\forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y)) \tag{1.84}$$

on the right-hand side of the proposed equivalence (1.81), we take an arbitrary $\bar{y}$, so that the previously established universal sentence (1.83) yields in particular the true sentence

$$\neg[\varphi(\bar{y}) \,\wedge\, \vartheta(\bar{y})], \tag{1.85}$$

which in turn implies

$$\neg\varphi(\bar{y}) \,\vee\, \neg\vartheta(\bar{y}) \tag{1.86}$$

with De Morgan's Law for sentences (1.51). This disjunction now further implies

$$\varphi(\bar{y}) \Rightarrow \neg\vartheta(\bar{y}) \tag{1.87}$$

with the Conditional Law (1.31), and since $\bar{y}$ was arbitrary, we may therefore conclude that the universal sentence (1.84) is true. Thus, the proof of the first part of the equivalence (1.81) is complete.

To prove the second part ('$\Leftarrow$'), we now assume the universal sentence (1.84) holds, and we show that the universal sentence (1.83) follows then to be true. To do this, we let $\bar{y}$ be arbitrary, so that the assumption (1.84) gives the true sentence (1.87). This implication then implies (1.86) with the Conditional Law (1.31), and furthermore (1.85) with De Morgan's Law for sentences (1.51). Because $\bar{y}$ is arbitrary, we may therefore conclude that the universal sentence (1.83) is indeed true, which in turn implies the truth of the equivalent negation $\neg\exists y(\varphi(y) \wedge \vartheta(y))$. This completes the proof of the second part of the equivalence, which is thus true.

Concerning (1.82), we observe in light of the true equivalence (1.81) that the implications

$$\neg\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))\ \Rightarrow\ \forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y))$$
$$\forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y))\ \Rightarrow\ \neg\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))$$

are true. Next, we apply the Law of Contraposition to both implications and obtain the true implications

$$\neg\forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y))\ \Rightarrow\ \neg\neg\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))$$
$$\neg\neg\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))\ \Rightarrow\ \neg\forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y)),$$

so that the equivalence

$$\neg\forall y\,(\varphi(y) \Rightarrow \neg\vartheta(y))\ \Leftrightarrow\ \neg\neg\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))$$

holds. Since the equivalence

$$\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))\ \Leftrightarrow\ \neg\neg\exists y\,(\varphi(y)\ \wedge\ \vartheta(y))$$

also holds because of the Double Negation Law, it follows with the Substitution Rule for equivalences (1.28) that the proposed equivalence (1.82) is true. $\square$

Exercise 1.15. Establish the following equivalences for arbitrary formulas $\varphi(x, y)$ and $\vartheta(x, y)$.

$$\neg\exists x, y\,(\varphi(x,y)\ \wedge\ \vartheta(x,y))\ \Leftrightarrow\ \forall x, y\,(\varphi(x,y) \Rightarrow \neg\vartheta(x,y)), \tag{1.88}$$
$$\neg\forall x, y\,(\varphi(x,y) \Rightarrow \neg\vartheta(x,y))\ \Leftrightarrow\ \exists x, y\,(\varphi(x,y)\ \wedge\ \vartheta(x,y)). \tag{1.89}$$

(Hint: Proceed in analogy to the proof of Theorem 1.19.)

Exercise 1.16. Prove the following equivalence for arbitrary formulas $\varphi(x)$, $\psi(y)$ and $\vartheta(x, y)$.

$$\forall x, y\,([\varphi(x)\ \wedge\ \psi(y)] \Rightarrow \vartheta(x,y))\ \Leftrightarrow\ \forall x\,(\varphi(x) \Rightarrow \forall y\,(\psi(y) \Rightarrow \vartheta(x,y))). \tag{1.90}$$

(Hint: Prove both parts of the equivalence directly.)

1.3.4. Equality

The following notion of 'sameness' will be fundamental.

Principle 1.4 (Leibniz' Law). Two given things x and y are equal or identical, symbolically

$$x = y, \tag{1.91}$$

iff x has every property that y has and y has every property that x has.

Definition 1.8 (Equation, inequality). For any x and y we call the sentence $x = y$ an *equation*. Furthermore, we say that x and y are *unequal* iff $\neg x = y$ is true, in which case we also write

$$x \neq y. \tag{1.92}$$

We then call this sentence an *inequality*.

We may consider the equality symbol $=$ as establishing a kind of *relation*[7] between x and y. The following notation is convenient in case there is another thing z besides y that related to x by equality.

Notation 1.3. We will also write

$$x = y = z \tag{1.93}$$

instead of

$$x = y \land y = z. \tag{1.94}$$

When an equation is given we may apply the fundamental method of *substitution*.

Method 1.16 (Substitution). Let $x = y$ be a true equation and $\varphi(x)$ a given sentence containing the constant x. Then we may substitute for x the identical y in $\varphi(x)$ and write $\varphi(y)$. Similarly, when $\psi(y)$ is another given sentence containing y, we may substitute for y the equal x in $\psi(y)$ and write $\psi(x)$.

The formation of equations follows four frequently applied rules, which are so basic that we will usually not refer to them explicitly.

Exercise 1.17. Show that the following sentences are true.

a) $=$ is *reflexive* in the sense that

$$\forall x\, (x = x), \tag{1.95}$$

[7] This notion will be given a formal definition in Chapter 3.

b) $=$ is *symmetrical* in the sense that

$$\forall x, y \,(x = y \Leftrightarrow y = x), \tag{1.96}$$

c) $=$ is *Euclidean* in the sense that

$$\forall x, y, z \,([x = z \,\wedge\, y = z] \Rightarrow x = y), \tag{1.97}$$

d) $=$ is *transitive* in the sense that

$$\forall x, y, z \,([x = y \,\wedge\, y = z] \Rightarrow x = z), \tag{1.98}$$

(Hint: Apply Method 1.14 and Method 1.16.)

Exercise 1.18. Show that the following sentence is true.

$$\forall x, y, z \,([x = y \Leftrightarrow x = z] \Leftrightarrow y = z). \tag{1.99}$$

(Hint: To prove '$\Rightarrow$', apply (1.8) and Method 1.11)

Exercise 1.19. Show that $\neq$ is *symmetrical* in the sense that

$$\forall x, y \,(x \neq y \Leftrightarrow y \neq x). \tag{1.100}$$

1.3.5. Unique existence

We will frequently encounter existential sentences which are true for *precisely one* constant.

Definition 1.9 (There exists a unique/there is a unique, uniquely existential sentence). For an arbitrary formula $\varphi(X)$, we say that *there exists a unique* (or that *there is a unique*) X such that $\varphi(X)$ holds, symbolically

$$\exists! X \,(\varphi(X)) \tag{1.101}$$

iff there exists a set X such that φ holds and there is no constant which also satisfies φ but is different from X, that is,

$$\exists X \,(\varphi(X) \,\wedge\, \neg\exists X^* \,(\varphi(X^*) \,\wedge\, X^* \neq X)). \tag{1.102}$$

In this case, we speak of a *uniquely existential sentence*.

Based on the following proposition, we will see how such a sentence can be proved conveniently.

Theorem 1.20 (Criterion for unique existence). *The following equivalence is true for an arbitrary formula $\varphi(X)$.*

$$\exists! X\,(\varphi(X)) \;\Leftrightarrow\; [\exists X\,(\varphi(X)) \;\wedge\; \forall X, X'\,([\varphi(X) \;\wedge\; \varphi(X')] \Rightarrow X = X')]\,. \tag{1.103}$$

Proof. To prove the first part ('$\Rightarrow$') of the proposed equivalence directly, we assume $\exists! X\,(\varphi(X))$, so that the existential sentence (1.102) holds by definition of a uniquely existential sentence. Thus, there exists a constant, say $\bar{X}$, such that the conjunction

$$\varphi(\bar{X}) \;\wedge\; \neg\exists X^*\,(\varphi(X^*) \;\wedge\; X^* \neq \bar{X})$$

is true. This means that the sentence $\varphi(\bar{X})$ and the negation

$$\neg\exists X^*\,(\varphi(X^*) \;\wedge\; X^* \neq \bar{X})$$

both hold. Here, we may write the latter equivalently as

$$\forall X^*\,(\varphi(X^*) \Rightarrow \neg X^* \neq \bar{X}) \tag{1.104}$$

by applying (1.81). The truth of $\varphi(\bar{X})$ shows that the first part of the conjunction in (1.103) to be proven is true. We now establish the second part

$$\forall X, X'([\varphi(X) \;\wedge\; \varphi(X')] \Rightarrow X = X'). \tag{1.105}$$

To do this, we let X and X' be arbitrary, and we prove the implication in (1.104) directly, assuming the conjunction $\varphi(X) \wedge \varphi(X')$ to be true. On the one hand, this conjunction implies the truth of $\varphi(X)$, which in turn implies $\neg X \neq \bar{X}$ with (1.104), and therefore $X = \bar{X}$ with the Double Negation Law. On the other hand, the preceding conjunction implies in particular $\varphi(X')$ and then $\neg X' \neq \bar{X}$ with (1.104), so that $X' = \bar{X}$ $[= X]$ follows to be true with the Double Negation Law. These equations yield $X = X'$, which proves the implication in (1.105). Since X and X' are arbitrary, we may therefore conclude that the universal sentence (1.105) holds, completing the proof of the conjunction in (1.103) and completing thus the proof of the first part of the proposed equivalence.

Next, we prove the second part ('$\Leftarrow$') of the equivalence (1.103) directly. For this purpose, we assume

$$\exists X\,(\varphi(X)) \;\wedge\; \forall X, X'\,([\varphi(X) \;\wedge\; \varphi(X')] \Rightarrow X = X')$$

is true. Then, both parts of this conjunction, $\exists X\,(\varphi(X))$ and (1.105) are true by themselves. Thus, there is a constant, say $\bar{\bar{X}}$, such that $\varphi(\bar{\bar{X}})$ is true. Let us now prove the universal sentence

$$\forall X^*\,(\varphi(X^*) \Rightarrow \neg X^* \neq \bar{\bar{X}}). \tag{1.106}$$

To do this, we take an arbitrary X^* and assume that $\varphi(X^*)$ holds. Thus, the conjunction $\varphi(X^*) \wedge \varphi(\bar{\bar{X}})$ is true, which further implies $X^* = \bar{\bar{X}}$ with the second part of the assumed conjunction. This equation gives with the Double Negation Law $\neg X^* \neq \bar{\bar{X}}$, which negation proves the implication in (1.106). Since X^* is arbitrary, we therefore conclude that the universal sentence (1.106) holds indeed, which in turn implies

$$\neg \exists X^* \, (\varphi(X^*) \wedge X^* \neq \bar{\bar{X}}))$$

with (1.81). Together with the true sentence $\varphi(\bar{\bar{X}})$, this shows that the conjunction

$$\varphi(\bar{\bar{X}}) \wedge \neg \exists X^* \, (\varphi(X^*) \wedge X^* \neq \bar{\bar{X}})$$

holds, so that the existential sentence

$$\exists X \, (\varphi(X) \wedge \neg \exists X^* \, (\varphi(X^*) \wedge X^* \neq X))$$

is evidently true. This means by definition of a uniquely existential sentence that $\exists! X \, (\varphi(X))$ holds, so that the proof of the equivalence (1.103) is complete. $\square$

The Criterion for unique existence yields the following proof technique.

Method 1.17 (Proof of a uniquely existential sentence). To carry out a proof of a uniquely existential sentence (1.102), we may in light of the Criterion for unique existence show by two separate proofs that

1. there exists a constant X for which $\varphi(X)$ is a true sentence, i.e.

$$\exists X \, (\varphi(X)), \tag{1.107}$$

   which we call the so-called *existential part*), and that

2. whenever two constants X and X' turn the given formula into true sentences they follow to be identical, i.e.

$$\forall X, X' \, ([\varphi(X) \wedge \varphi(X')] \Rightarrow X = X'), \tag{1.108}$$

   which we call the *uniqueness part*.

We demonstrate the application of this method by establishing another basic property of '='.

Proposition 1.21. *For any y there exists a unique x which is identical with y holds, that is,*

$$\forall y \, (\exists! x \, (x = y)). \tag{1.109}$$

Proof. To prove the universal sentence, we let $\bar{y}$ be arbitrary and apply then Method 1.17, letting $\varphi(x)$ be the formula $x = \bar{y}$. Regarding the existential part, we observe that $\bar{y}$ satisfies $\bar{y} = \bar{y}$ due to the reflexivity (1.95) of '='; thus, the existential sentence $\exists y(\varphi(y))$ is true. Regarding the uniqueness part, we verify

$$\forall x, x' \left([\varphi(x) \wedge \varphi(x')] \Rightarrow x = x' \right). \tag{1.110}$$

To do this, we let x and x' be arbitrary and prove the implication directly, assuming $\varphi(x) \wedge \varphi(x')$ to be true sentences, which mean that the equations $x = \bar{y}$ and $x' = \bar{y}$ are both true. This conjunction implies the desired $x = x'$ since '=' is Euclidean according to (1.97). Since x and x' are arbitrary, we may therefore conclude that the universal sentence (1.110) is true, so that the uniqueness part holds as well. Thus, the proof of the uniquely existential sentence (1.109) is true, and as Y was arbitrary, it follows that the proposition is true. □

If a certain constant X^* turns a given formula $\varphi(X)$ into a true sentence and if we can demonstrate that any other constant X for which $\varphi(X)$ is true turns out to be identical with X^*, we would naturally say that X^* is the only constant for which that sentence holds. Evidently then, such a demonstration should be a suitable method for proving a uniquely existential sentence.

Proposition 1.22. *The following implication is true for an arbitrary given formula $\varphi(X)$ and an arbitrary given constant $\bar{X}$.*

$$[\varphi(\bar{X}) \wedge \forall X \left(\varphi(X) \Rightarrow \bar{X} = X \right)] \;\Rightarrow\; \exists! X \, \varphi(X). \tag{1.111}$$

Proof. We prove the implication directly, assuming that $\varphi(\bar{X})$ and

$$\forall X \left(\varphi(X) \Rightarrow \bar{X} = X \right) \tag{1.112}$$

are true sentences. The first of these two assumptions shows that the existential sentence $\exists X \, \varphi(X)$ holds, which proves the existential part of the proof of the uniquely existential sentence $\exists! X \, \varphi(X)$. To prove the uniqueness part, we verify

$$\forall X, X' \left([\varphi(X) \wedge \varphi(X')] \Rightarrow X = X' \right). \tag{1.113}$$

For this purpose, we take arbitrary constants X and X' and assume $\varphi(X) \wedge \varphi(X')$ to be true. This conjunction implies, on the one hand, especially the truth of $\varphi(X)$, which in turn implies

$$\bar{X} = X \tag{1.114}$$

with the assumption (1.112). On the other hand, the preceding conjunctions shows that the sentence $\varphi(X')$ holds, which further implies

$$\bar{X} = X' \tag{1.115}$$

with (1.112). Clearly, combining the equations (1.114) and (1.115) via substitution yields $X = X'$, which finding proves the implication in (1.113). Then, as X and X' were arbitrary, we may therefore conclude that the universal sentence (1.113) holds. Thus, the proof of the uniquely existential sentence $\exists! X\, \varphi(X)$ is complete, and the truth of this sentence establishes the proposed implication. □

Method 1.18 (Proof of a uniquely existential sentence (variant)). To carry out a proof of a uniquely existential sentence $\exists! X\, \varphi(X)$ for a given formula $\varphi(X)$, we may find a particular constant $\bar{X}$ for which $\varphi(X)$ becomes a true sentence and prove then the universal sentence

$$\forall X' \,(\varphi(X') \Rightarrow \bar{X} = X'). \tag{1.116}$$

We define uniquely an existential sentence involving two variables in analogy to the Criterion for unique existence (for a single variable).

Notation 1.4. We will also write

$$\exists! X, Y\, (\varphi(X, Y)) \tag{1.117}$$

instead of

$$\begin{aligned} &\exists X, Y\, (\varphi(X, Y)) \\ &\quad \wedge\ \forall X, Y, X', Y'\, ([\varphi(X, Y)\ \wedge\ \varphi(X', Y')] \Rightarrow [X = X'\ \wedge\ Y = Y']). \end{aligned} \tag{1.118}$$

Exercise 1.20. Establish the equivalence of the existential sentence

$$\exists X, Y\, (\varphi(X, Y)\ \wedge\ \neg\exists X^*, Y^*\, (\varphi(X^*, Y^*)\ \wedge\ [X^* \neq X\ \vee\ Y^* \neq Y]))$$

and the conjunction (1.118).

(Hint: Use similar arguments as in the proof of Theorem 1.20, replacing (1.35) by (1.52) and replacing (1.81) by (1.88).)

Chapter 2.

Sets

2.1. Basic Characteristics of Sets

Definition 2.1 (Set, element, set system). In Georg Cantor's words:

> Unter einer 'Menge' verstehen wir jede Zusammenfassung M von bestimmten wohlunterschiedenen Objecten m unsrer Anschauung oder unseres Denkens (welche die 'Elemente' von M genannt werden) zu einem Ganzen. (Cantor, 1895, p.481).

That is, we understand a *set* to be any aggregation M of certain and clearly distinct objects within our perception or conception (which are called the *elements* of M) to a whole.

We also say that a set *contains* elements. More specifically, we say that a set *consists of* certain elements in case the set contains precisely these elements and no other elements. To express that y is an element of a set A, we write

$$y \in A \tag{2.1}$$

In case we consider multiple elements x, y, etc. of A, we write instead of $(y \in A \land z \in A) \land \cdots$ the shorter sentence

$$y, z, \ldots \in A \tag{2.2}$$

Furthermore, we write

$$y \notin A \tag{2.3}$$

iff it is false that y is in A, that is, iff $\neg y \in A$ is true.

In certain situations, we wish to highlight the fact that a given set consists itself of certain sets, in which case we will also speak of a *set system*.

We may use the concept of non-membership '$\notin$' to characterize distinctness '$\neq$'.

Proposition 2.1. *If x is an element of a set A and if y is not in A, then x and y are distinct, that is,*

$$\forall A, x, y\,([x \in A \,\wedge\, y \notin A] \Rightarrow x \neq y). \tag{2.4}$$

Proof. We let x and y be arbitrary and prove the implication by contradiction, assuming that the conjunction of $x \in A$, $y \notin A$ and $x = y$ holds. Because of the equation, we may substitute y for x in $x \in A$, which gives $y \in A$. Thus, $y \in A$ and the assumption $y \notin A$ are both true, so that we have a contradiction according to (1.11). This completes the proof by contradiction of the implication in (2.4). As x and y were arbitrary, we therefore conclude that the universal sentence (2.4) is true. □

Conversely, we may characterize non-membership '$\notin$' by means of distinctness '$\neq$'.

Proposition 2.2. *A y is not an element of a set A iff any x in A is different from y, that is,*

$$\forall A, y\,(y \notin A \Leftrightarrow \forall x\,(x \in A \Rightarrow x \neq y)). \tag{2.5}$$

Proof. We let A and y be arbitrary and assume first $y \notin A$ to be true. To show that this implies

$$\forall x\,(x \in A \Rightarrow x \neq y), \tag{2.6}$$

we let x be arbitrary and assume $x \in A$ to be true. The conjunction of this assumption and the initially assumed $y \notin A$ then implies the desired consequent $x \neq y$ with (2.4). Since x is arbitrary, we may therefore conclude that the universal sentence (2.6) is true, so that the first part ('$\Rightarrow$') of the proposed equivalence holds. We now prove the second part ('$\Leftarrow$') by contradiction, assuming (2.6) and $\neg y \notin A$ to be both true. The latter assumption yields with the Double Negation Law $y \in A$, which in turn implies with the assumed (2.6) that $y \neq y$, in contradiction to the fact that $y = y$ holds. Thus, the proof of the equivalence is complete, and since A and y were arbitrary, we may therefore conclude that the proposed universal sentence (2.5) is true. □

Notation 2.1. We will generally use calligraphic letters (e.g. $\mathcal{A}$, $\mathcal{X}$) to denote set systems, upper case letters (e.g. A, X) to represent either the set elements of a set system or just sets without reference to a set system, and lower case letters (e.g. a, x, etc.) for elements of a set.

We now describe the situation in which all elements of a given set can be found in another set.

Definition 2.2 (Subset). For any sets A and B we say that A is a *subset* of B, symbolically

$$A \subseteq B, \tag{2.7}$$

if, and only if,

$$\forall y\,(y \in A \Rightarrow y \in B). \tag{2.8}$$

We then also say that B *includes* A.

Proposition 2.3. *If an y is not element of a set B, then y is not element of any subset of B either, that is,*

$$\forall A, B, y\,([A \subseteq B \,\wedge\, y \notin B] \Rightarrow y \notin A). \tag{2.9}$$

Proof. We let A, B and y be arbitrary, assume that A is a subset of B, and we further assume that y is not in B. Here, the assumption $A \subseteq B$ implies with the definition of a subset

$$\forall x\,(x \in A \Rightarrow x \in B),$$

so that $y \in A \Rightarrow y \in B$ is true in particular. We may write this implication equivalently as $y \notin B \Rightarrow y \notin A$, so that the initial assumption $y \notin B$ implies $y \notin A$. This proves the implication in (2.9), and since A, B and y were arbitrary, we may therefore conclude that the proposed universal sentence (2.9) is true. □

Proposition 2.4. *Any set is a subset of itself, that is,*

$$\forall B\,(B \subseteq B). \tag{2.10}$$

Proof. We let B be an arbitrary set and prove $B \subseteq B$ by verifying the equivalent universal sentence (using the definition of a subset)

$$\forall y\,(y \in B \Rightarrow y \in B). \tag{2.11}$$

For this purpose, we let y be arbitrary and observe then the truth of the disjunction $y \in B \,\vee\, y \notin B$. If $y \in B$ is true, both the antecedent and the consequent of the implication in (2.11) are true, so that the implication itself also holds. If $y \notin B$ is true, then the antecedent of the implication is false, and therefore the implication itself is again true. Since y was arbitrary, we may therefore conclude that the universal sentence (2.11) holds, which means $B \subseteq B$ by definition of a subset. As B was an arbitrary set, we may then further conclude that the proposed universal sentence (2.10) is true. □

The concepts of a subset and equality of sets involve universal quantification, requiring the specification of a domain of discourse. From now on, this domain will consist only of sets and, for maximum flexibility, consist of all conceivable sets.

Definition 2.3 (Universe). We say that U is the *universe* iff U is the domain of discourse consisting of all possible sets[1], symbolically

$$U = \{A : A = A\}. \tag{2.12}$$

Note 2.1. Since $A = A$ is a tautology, the sets within the universe do not have any specific and thereby limiting property.

Proposition 2.5. *The inclusion $\subseteq$ is transitive in the sense that*

$$\forall A, B, C\,([A \subseteq B \,\wedge\, B \subseteq C] \Rightarrow A \subseteq C). \tag{2.13}$$

Proof. To prove the stated universal sentence (using Method 1.14) we let A, B, C be arbitrary sets within the universe. Then, to prove the implication directly (applying Method 1.6), we assume $A \subseteq B \,\wedge\, B \subseteq C$, which means that

$$\forall y\,(y \in A \Rightarrow y \in B) \tag{2.14}$$

and

$$\forall y\,(y \in B \Rightarrow y \in C) \tag{2.15}$$

are both true by Definition 2.2. To show that this implies $A \subseteq C$, that is,

$$\forall y\,(y \in A \Rightarrow y \in C), \tag{2.16}$$

we let y be arbitrary and and prove the implication directly, assuming $y \in A$ to be true. This assumption implies with (2.14) the truth of $y \in B$, which in turn implies $y \in C$ with (2.15). Thus, the direct proof of the implication in (2.16) is complete, so that the inclusion $A \subseteq C$ follows to be by definition of a subset true. This finding completes the direct proof of the implication in (2.13), and since A, B, C were arbitrary sets, we may conclude that the proposed universal sentence (2.13) is true. $\square$

Note 2.2. Proposition 2.5 may be viewed as a set-theoretical analog to the Law of the Hypothetical Syllogism.

[1] It can be shown by means of a proof by contradiction that this domain of all possible sets is itself not a set, which is known as *Russel's paradox*. Such an 'improper' set is sometimes called a *class*.

We now apply the principle of equality of general things specifically to sets. In case every element of set A is in a set B and also every element of B is in A, we clearly have two sets consisting of the same elements. The following axiom states that we then consider the two sets to be equal (so that there are no other properties that A and B must share in order to be identical).

Axiom 2.1 (Axiom of Extension). For any sets A and B (within the universe) it is true that, if A is a subset of B and also B a subset of A, then A and B are equal, i.e.,

$$\forall A, B\,([A \subseteq B \,\land\, B \subseteq A] \Rightarrow A = B). \tag{2.17}$$

The following proposition includes this implication and also shows that we do not need another assumption to justify the reversed implication.

Theorem 2.6 (Equality Criterion for sets). *Any two sets A and B are identical if, and only if, every element of A is also an element of B and each element in B is also in A, i.e.*

$$\forall A, B\,(A = B \Leftrightarrow \forall y\,(y \in A \Leftrightarrow y \in B)). \tag{2.18}$$

Proof. To prove the universal sentence, we let A and B be arbitrary sets (within the universe). To verify the equivalence, we first prove the implication ('$\Rightarrow$')

$$A = B \;\Rightarrow\; \forall y\,(y \in A \Leftrightarrow y \in B) \tag{2.19}$$

directly, assuming $A = B$. To show that the consequent

$$\forall y\,(y \in A \Leftrightarrow y \in B) \tag{2.20}$$

holds, we let y be arbitrary and observe in light of Principle 1.4 that $A = B$ means that A and B share all of their properties, in particular that of consisting of certain elements. Clearly, this means that y is an element of A if, and only if, y is also an element of B. Since y is arbitrary, we may therefore conclude that the universal sentence (2.20) is true, so that the first implication (2.19) holds.

To prove the second implication ('$\Leftarrow$')

$$\forall y\,(y \in A \Leftrightarrow y \in B) \;\Rightarrow\; A = B \tag{2.21}$$

directly, we now assume the universal sentence (2.20) to be true. Let us now observe the truth of the equivalences

$$\begin{aligned} A \subseteq B \,\land\, B \subseteq A \;&\Leftrightarrow\; \forall y\,(y \in A \Rightarrow y \in B) \,\land\, \forall y\,(y \in B \Rightarrow y \in A) \\ &\Leftrightarrow\; \forall y\,([y \in A \Rightarrow y \in B] \,\land\, [y \in A \Rightarrow y \in B]). \end{aligned}$$

in light of the definition of a subset in connection with the Substitution Rules for conjunctions and the Distributive Law for quantification (1.74). Evidently, the preceding universal sentence

$$\forall y\,([y \in A \Rightarrow y \in B] \wedge [y \in A \Rightarrow y \in B])$$

is equivalent to the antecedent in (2.21) due to (1.8), since the conjunction

$$[y \in A \Rightarrow y \in B] \wedge [y \in A \Rightarrow y \in B]$$

defines for an arbitrary y the equivalence $y \in A \Leftrightarrow y \in B$. In view of the previously established equivalences, the conjunction $A \subseteq B \wedge B \subseteq$ is then according to the Substitution Rules for equivalences also equivalent to the antecedent in (2.21). Therefore, the assumed truth of the latter implies the truth of the former, i.e. the truth of $A \subseteq B \wedge B \subseteq$, which in turn implies $A = B$ with the Axiom of Extension. This completes the proof of the second part ('$\Leftarrow$') of the equivalence in (2.18).

Since both parts of the equivalence in (2.18) are true and since A and B are arbitrary sets, we may finally conclude that the proposition holds. □

Method 2.1 (Verification that two given sets are identical). To verify that two given sets A and B are equal, we may show that $y \in A$ implies $y \in B$ and that $y \in B$ implies $y \in A$ for any y.

Corollary 2.7. *Two sets A and B are identical iff A is a subset of B and B a subset of A, that is,*

$$\forall A, B\,(A = B \Leftrightarrow [A \subseteq B \wedge B \subseteq A]). \tag{2.22}$$

Proof. We let A and B be arbitrary sets and recall from the proof of the Equality Criterion for sets that the equivalence

$$\forall y\,(y \in A \Leftrightarrow y \in B) \Leftrightarrow [A \subseteq B \wedge B \subseteq A]$$

holds. Since the equivalence

$$A = B \Leftrightarrow \forall y\,(y \in A \Leftrightarrow y \in B)$$

is also true according to the Equality Criterion for sets, we obtain the equivalence in (2.22) by applying the Substitution Rule for equivalences (1.29). As A and B are arbitrary, we may therefore conclude that the corollary is true. □

Exercise 2.1. Show that two sets A and B are unequal iff there is an element which is in A but not in B or in B but not in A, that is,

$$\forall A, B\,(A \neq B \Leftrightarrow \exists y\,([y \in A \wedge y \notin B] \vee [y \in B \wedge y \notin A])). \tag{2.23}$$

(Hint: Use Definition 1.8, (2.18), (1.53), (1.8), (1.51), (1.32), and (2.1).)

We will occasionally apply the concept of a subset in a version which excludes the possibility that the two sets are equal.

Definition 2.4 (Proper subset). For any sets A and B we say that A is a *proper subset* of B, symbolically

$$A \subset B, \tag{2.24}$$

iff A is a subset of but not equal to B, that is,

$$A \subseteq B \wedge A \neq B. \tag{2.25}$$

We may then characterize a subset also

Proposition 2.8. *A is a subset of B iff A is a proper subset of or equal to B, that is,*

$$\forall A, B\,(A \subseteq B \Leftrightarrow [A \subset B \vee A = B]). \tag{2.26}$$

Proof. We let A and B be arbitrary sets and observe first the truth of the equivalences

$$\begin{aligned}
A \subset B \vee A = B \;&\Leftrightarrow\; (A \subseteq B \wedge A \neq B) \vee A = B \\
&\Leftrightarrow\; A = B \vee (A \subseteq B \wedge A \neq B) \\
&\Leftrightarrow\; (A = B \vee A \subseteq B) \wedge (A = B \vee A \neq B) \\
&\Leftrightarrow\; A = B \vee A \subseteq B
\end{aligned}$$

using (2.25) in connection with the Substitution Rule for disjunctions (1.25), the Commutative Law for the disjunction, the Distributive Law for sentences (1.45), and (1.13) in connection with the fact that the disjunction $A = B \vee A \neq B$ is a tautology according to (1.10). Consequently, the equivalence

$$[A \subset B \vee A = B] \Leftrightarrow [A = B \vee A \subseteq B] \tag{2.27}$$

follows to be true with the Substitution Rule for equivalences (1.29).

We now prove the first part ('$\Rightarrow$') of the equivalence in (2.26) directly, assuming that $A \subseteq B$ holds. Then, the disjunction $A = B \vee A \subseteq B$ is also true (irrespective of the truth value of $A = B$), which in turn implies $A \subset B \vee A = B$ with (2.27), so that the proof of ('$\Rightarrow$') is complete.

To prove the second part ('$\Leftarrow$') directly, we assume now the disjunction $A \subset B \vee A = B$ to be true, which implies with (2.27) the disjunction $A = B \vee A \subseteq B$. If the first part $A = B$ holds, then it follows with the Equality Criterion for sets that $A \subseteq B \wedge B \subseteq A$ is also true, which conjunction implies in particular the desired inclusion $A \subseteq B$. If the second part $A \subseteq B$ of the preceding disjunction holds, then we arrived already at the desired consequent. Thus, $A \subseteq B$ holds in any case, and the proof of ('$\Leftarrow$') is complete.

Therefore, the equivalence in (2.26) is true, and since A and B were arbitrary, we may therefore conclude that the proposition holds, as claimed. $\square$

Note 2.3. We see clearly in (2.26) that the fact $B = B$ implies $B \subseteq B$ for any set B, which we established already in Proposition 2.4.

In the remainder of this section, we will introduce two key concepts which, applied together, allow us to define sets with particular properties. First, we give the concept of a property of a general thing a narrower set-theoretical meaning.

Definition 2.5 (Definite property). Letting $\varphi(X, Y, \ldots)$ be an arbitrary formula where the variables X, Y, etc., are sets, we say that $\varphi(X, Y, \ldots)$ is a *definite property* of X iff X is a free variable and $Y, \ldots$ are bound variables.

Example 2.1. The formula

$$\forall y, A\,([y \in A \,\wedge\, A \in \mathcal{S}] \Rightarrow y \in \mathcal{S}) \tag{2.28}$$

is a definite property of the set system $\mathcal{S}$; in this instance $\mathcal{S}$ is said to have the definite property of being a 'transitive set'.

The second concept for defining a particular set claims the existence of a set obtained by 'picking out' all those elements from a given set which have a certain property.

Axiom 2.2 (Axiom of Specification/comprehension scheme). For an arbitrary formula $\varphi(y, G, A, B, \ldots)$ and for any sets G, A, B, etc., there exists a set X which contains all the elements of G for which φ is a true sentence, that is,

$$\exists X\, \forall y(y \in X \Leftrightarrow [y \in G \,\wedge\, \varphi(y, G, A, B, \ldots)]). \tag{2.29}$$

Note 2.4. (2.29) constitutes a scheme when φ is not fixed beforehand.

In the following section we will apply the previously introduced concepts to define various basic types of sets. Our main goal will be the construction of the 'set of natural numbers', which set will allow us to count computational quantities such as numerical observations.

2.2. The Empty Set $\emptyset$

Let us now apply the Axiom of Specification in connection with the Equality Criterion for sets (which is essentially based on the Axiom of Extension), to establish the concept of an 'empty set'.

Theorem 2.9 (Unique existence of a set without elements). *There exists a unique set which does not contain any elements, that is,*

$$\exists! X\, \forall y\, (y \notin X), \tag{2.30}$$

Proof. First, we establish the uniqueness part and prove accordingly

$$\exists X\, \forall y\, (y \notin X). \tag{2.31}$$

For this purpose, we let $\varphi(y)$ be the formula

$$y \neq y$$

and let G be an arbitrary set within the universe. We may then apply the Axiom of Specification to obtain the true sentence

$$\exists X\, \forall y\, (y \in X \Leftrightarrow [y \in G \,\wedge\, \varphi(y)]).$$

Thus, there exists a set, say $\bar{X}$, which contains every element of G for which $\varphi(y)$ is true, which means that the set $\bar{X}$ satisfies

$$\forall y\, (y \in \bar{X} \Leftrightarrow [y \in G \,\wedge\, y \neq y]). \tag{2.32}$$

We now prove that the set $\bar{X}$ satisfies also

$$\forall y\, (y \notin \bar{X}). \tag{2.33}$$

To do this, we let $\bar{y}$ be arbitrary, so that the equivalence

$$\bar{y} \in \bar{X} \Leftrightarrow [\bar{y} \in G \,\wedge\, \bar{y} \neq \bar{y}]$$

holds in view of (2.32). Since $\bar{y} \neq \bar{y}$ is false due to (1.95), the conjunction

$$\bar{y} \in G \,\wedge\, \bar{y} \neq \bar{y}$$

is then also false. Consequently, the preceding equivalence shows that $\bar{y} \in \bar{X}$ is also false, which we may also write as $\bar{y} \notin \bar{X}$ because of (2.3). As $\bar{y}$ was arbitrary, we may therefore conclude that the universal sentence (2.33) is true. We thus showed that there exists a set X satisfying $\forall y\, (y \notin X)$, which proves the existential sentence (2.31) and thus the existential part of the uniquely existential sentence to be proven.

To establish the uniqueness part, we now prove

$$\forall X, X' \, ([\forall y \, (y \notin X) \, \wedge \, \forall y \, (y \notin X')] \Rightarrow X = X'). \tag{2.34}$$

For this purpose, we let X and X' be arbitrary and prove the implication in (2.34) directly, assuming the antecedent

$$\forall y \, (y \notin X) \, \wedge \, \forall y \, (y \notin X')$$

to be true. As a conjunction is only true when both of its parts are true, we have that

$$\forall y \, (y \notin X) \tag{2.35}$$

and

$$\forall y \, (y \notin X') \tag{2.36}$$

both hold. To show that this implies $X = X'$, we verify

$$\forall y \, (y \in X \Leftrightarrow y \in X'). \tag{2.37}$$

To prove this universal sentence, we let $\bar{y}$ be arbitrary, so that $\bar{y} \notin X$ is true because of (2.35), and futhermore $\bar{y} \notin X'$ holds due to (2.36). Thus, the negations $\neg \bar{y} \in X$ and $\neg \bar{y} \in X'$ are both true, which means that $\bar{y} \in X$ and $\bar{y} \in X'$ are both false. Therefore, the equivalence in (2.37) takes the truth value 'T', and since $\bar{y}$ was arbitrary, we may further conclude that this equivalence holds for any y. This completes the proof of the universal sentence (2.37), which in turn implies $X = X'$ with (2.18). This equation proves the implication in (2.34), and as X and X' were arbitrary, we may therefore conclude that the universal sentence (2.34) is also true. This completes the proof of the uniqueness part of the proposed uniquely existential sentence (2.30), which is thus true. □

Note 2.5. The reason for choosing the formula $y \neq y$ is that it becomes a false sentence for any y, so that the sentence $y \in \bar{X}$ in (2.32) is also false, as desired. It is therefore possible to replace $y \neq y$ by any other formula which turns into a false sentence for any y.

Definition 2.6 (Empty set). For any set A we say that A is the *empty set*, symbolically

$$A = \emptyset \quad \text{or} \quad A = \{\,\} \quad \text{or} \quad A = \{y : y \neq y\}, \tag{2.38}$$

iff A does not contain any elements, that is, iff

$$\forall y \, (y \notin A). \tag{2.39}$$

Note 2.6. "We say that a set A (...)" abbreviates "For any set A we say that A (...)".

Note 2.7. Clearly, the equation $\emptyset = \emptyset$ holds, so that the preceding definition implies

$$\forall y\,(y \notin \emptyset). \tag{2.40}$$

Corollary 2.10. *There exists no element in the empty set, that is,*

$$\neg \exists y\,(y \in \emptyset). \tag{2.41}$$

Proof. Since $\forall y\,(y \notin \emptyset)$ holds by definition of the empty set, which we may also write as $\forall y\,(\neg y \in \emptyset)$, we may apply the Quantifier Negation Law (1.54) to obtain the equivalently true sentence (2.41). □

Proposition 2.11. *A set A is nonempty iff there is an y in A, that is,*

$$\forall A\,(A \neq \emptyset \Leftrightarrow \exists y\,(y \in A)). \tag{2.42}$$

Proof. We let A be an arbitrary set and first observe the truth of the equivalences

$$\begin{aligned} A \neq \emptyset \;&\Leftrightarrow\; \neg A = \emptyset \\ &\Leftrightarrow\; \neg \forall y\,(y \notin A) \\ &\Leftrightarrow\; \neg(\neg \exists y\,(y \in A)) \\ &\Leftrightarrow\; \exists y\,(y \in A) \end{aligned}$$

due to the definition of an inequality, the definition of the empty set, the Quantifier Negation Law (1.54), and the Double Negation Law. Then, the Substitution Rule for equivalences (1.29) gives the desired equivalence in (2.42), and since A is arbitrary, we may therefore conclude that the proposition holds. □

Proposition 2.12. *The empty set is included any set, that is,*

$$\forall A\,(\emptyset \subseteq A). \tag{2.43}$$

Proof. We let A be arbitrary and prove the inclusion $\emptyset \subseteq A$ by verifying the equivalent (using the definition of a subset)

$$\forall y\,(y \in \emptyset \Rightarrow y \in A). \tag{2.44}$$

Letting y be arbitrary, we now see that $\neg y \in \emptyset$ holds by definition of the empty set, so that $y \in \emptyset$ is false. Thus, the implication in (2.44) has a false antecedent and is therefore true. Since y is arbitrary, we may therefore conclude that the universal sentence (2.44) is true. Then, $\emptyset \subseteq A$ follows to be true by definition of a subset, and as A was also arbitrary, we may further conclude that the proposed universal sentence (2.43) holds. □

Note 2.8. The preceding Proposition 2.12 shows in particular that the empty set is included in itself, that is,

$$\emptyset \subseteq \emptyset. \tag{2.45}$$

Proposition 2.13. *Any subset of the empty set is identical with the empty set, that is,*

$$\forall A \, (A \subseteq \emptyset \Leftrightarrow A = \emptyset). \tag{2.46}$$

Proof. We let A be an arbitrary set and prove the first implication '$\Rightarrow$' directly, assuming $A \subseteq \emptyset$ to be true. Since $\emptyset \subseteq A$ also holds according to (2.43), we see that the conjunction $A \subseteq \emptyset \wedge \emptyset \subseteq A$ is true. It then follows with the Axiom of Extension that the desired equation $A = \emptyset$ holds. Assuming conversely $A = \emptyset$ to be true, we obtain from the (2.45) via substitution the desired consequent $A \subseteq \emptyset$ also of the second implication '$\Leftarrow$', so that the proof of the equivalence in (2.46) is complete. Since A was an arbitrary set, we may therefore conclude that the proposition is true. $\square$

Proposition 2.14. *There is no proper subset of the empty set, that is,*

$$\neg \exists A \, (A \subset \emptyset). \tag{2.47}$$

Proof. We first observe that (2.47) is equivalent to

$$\forall A \, (\neg A \subset \emptyset) \tag{2.48}$$

due to the Quantifier Negation Law (1.54). To prove that universal sentence, we now let A be arbitrary and prove the negation $\neg A \subset \emptyset$ by contradiction, assuming $A \subset \emptyset$ to be true. By definition of a proper subset, this means that the conjunction $A \subseteq \emptyset \wedge A \neq \emptyset$ holds. This implies in particular $A \subseteq \emptyset$, which in turn implies $A = \emptyset$ with (2.46). Thus, $A = \emptyset$ and $A \neq \emptyset$ are both true, so that we obtained a contradiction according to (1.11), and the proof of $\neg A \subset \emptyset$ is complete. As A was arbitrary, we therefore conclude that the universal sentence (2.48) is true, which means that the equivalent negated existential sentence (2.47) also holds. $\square$

We use the empty set to define our first *number*.

Definition 2.7 (Zero). We say that a set A is the (*number*) *zero*, symbolically $A = 0$, iff $A = \emptyset$.

Note 2.9. The fact that $A = 0 \Leftrightarrow A = \emptyset$ (for any A) is equivalent to $0 = \emptyset$ due to (1.99) justifies the following alternative, shorter definition of 0.
"We call

$$0 = \emptyset. \tag{2.49}$$

the number zero."

2.3. Intersections of Sets

With the Axiom of Specification and the Equality Criterion for sets, we may also form a unique set by extracting from two given sets all elements that they have in common. Such a set may be viewed as the 'overlap' of two sets.

Theorem 2.15. *For any sets A and B there exists a unique set X such that an element y is in X iff y is in A and in B, i.e.*

$$\exists! X\, \forall y\, (y \in X \Leftrightarrow [y \in A \,\wedge\, y \in B]). \tag{2.50}$$

Proof. We let A and B be arbitrary sets and define $\varphi(y)$ to be the formula

$$y \in B.$$

Then, the Axiom of Specification yields the true existential sentence

$$\exists X\, \forall y\, (y \in X \Leftrightarrow [y \in A \,\wedge\, \varphi(y)]),$$

which proves the existential part of the uniquely existential sentence (2.50) to be proven. Regarding the uniqueness part, we now prove

$$\begin{aligned}&\forall X, X' \, ([\forall y\, (y \in X \Leftrightarrow [y \in A \,\wedge\, y \in B]) \,\wedge\, \forall y\, (y \in X' \Leftrightarrow [y \in A \,\wedge\, y \in B])] \\ &\quad \Rightarrow X = X').\end{aligned} \tag{2.51}$$

For this, purpose, we let X and X' be arbitrary and prove the implication directly, assuming that

$$\forall y\, (y \in X \Leftrightarrow [y \in A \,\wedge\, y \in B]) \,\wedge\, \forall y\, (y \in X' \Leftrightarrow [y \in A \,\wedge\, y \in B])$$

holds. Thus, the two parts

$$\forall y\, (y \in X \Leftrightarrow [y \in A \,\wedge\, y \in B]) \tag{2.52}$$

and

$$\forall y\, (y \in X' \Leftrightarrow [y \in A \,\wedge\, y \in B]) \tag{2.53}$$

of the preceding conjunction are true. Next, we establish the truth of

$$\forall y\, (y \in X \Leftrightarrow y \in X'), \tag{2.54}$$

letting $\bar{y}$ be arbitrary. Then, in view of (2.52) and (2.53), the equivalences

$$\bar{y} \in X \Leftrightarrow [\bar{y} \in A \,\wedge\, \bar{y} \in B]$$

and

$$\bar{y} \in X' \Leftrightarrow [\bar{y} \in A \wedge \bar{y} \in B]$$

are both true. Consequently, the conjunction of these two equivalences implies with the Substitution Rule for equivalences the truth of

$$\bar{y} \in X \Leftrightarrow \bar{y} \in X'.$$

As $\bar{y}$ was arbitrary, the universal sentence (2.54) follows therefore to be true, which then further implies $X = X'$ with the Equality Criterion for sets. Then, since X and X' were also arbitrary, we may therefore conclude that (2.51) holds, which proves the uniqueness part. Thus, the proof of the uniquely existential sentence (2.50) is complete. Finally, because the sets A and B were arbitrary as well, we may finally conclude that the proposed universal sentence is true. □

Note 2.10. Thus, the set X is (for any A and any B) uniquely specified by

$$\forall y \, (y \in X \Leftrightarrow [y \in A \wedge y \in B]),$$

which property we will use in the following definition.

Definition 2.8 (Intersection of two sets). For any sets A and B we say that a set X is the *intersection* of A and B, symbolically

$$X = A \cap B \quad \text{or} \quad X = \{y : y \in A \wedge y \in B\}, \tag{2.55}$$

iff X contains precisely all the elements in A and B in the sense that

$$\forall y \, (y \in X \Leftrightarrow [y \in A \wedge y \in B]). \tag{2.56}$$

Note 2.11. For any sets A and B, the evident truth of the equation $A \cap B = A \cap B$ implies by definition of the intersection of two sets

$$\forall y \, (y \in A \cap B \Leftrightarrow [y \in A \wedge y \in B]). \tag{2.57}$$

Theorem 2.16 (Commutative Law for the intersection of two sets). *The intersection of a set A and a set B is identical with the intersection of B and A, that is,*

$$\forall A, B \, (A \cap B = B \cap A). \tag{2.58}$$

Proof. We let A and B be arbitrary sets and prove the stated equation by verifying

$$\forall y \, (y \in A \cap B \Leftrightarrow y \in B \cap A). \tag{2.59}$$

To do this, we let y be arbitrary and observe the truth of the equivalences

$$\begin{aligned} y \in A \cap B &\Leftrightarrow (y \in A \wedge y \in B) \\ &\Leftrightarrow (y \in B \wedge y \in A) \\ &\Leftrightarrow y \in B \cap A, \end{aligned}$$

applying (2.57), then the Commutative Law for the conjunction, and then again (2.57). Thus, the Substitution Rule for equivalences (1.29) yields the desired equivalence $y \in A \cap B \Leftrightarrow y \in B \cap A$. Since y is arbitrary, we may therefore conclude that the universal sentence (2.59) is true, which then yields the desired equation $A \cap B = B \cap A$ with the Equality Criterion for sets. As A and B were also arbitrary, we may then further conclude that the proposed commutative law is indeed true. □

Theorem 2.17 (Idempotent Law for the intersection of two sets). *The pairwise intersection is idempotent in the sense that*

$$\forall A\,(A \cap A = A). \tag{2.60}$$

Proof. We let A be an arbitrary set and prove the stated equation by verifying

$$\forall y\,(y \in A \cap A \Leftrightarrow y \in A). \tag{2.61}$$

To do this, we let y be arbitrary and observe the truth of the equivalences

$$\begin{aligned} y \in A \cap A &\Leftrightarrow (y \in A \wedge y \in A) \\ &\Leftrightarrow y \in A, \end{aligned}$$

applying (2.57) and then the Idempotent Law for the conjunction. Thus, the Substitution Rule for equivalences (1.29) yields the desired equivalence $y \in A \cap A \Leftrightarrow y \in A$. Since y is arbitrary, we may therefore conclude that the universal sentence (2.61) is true, which then yields the desired equation $A \cap A = A$ with the Equality Criterion for sets. As A was also arbitrary, we may then further conclude that the proposed law is indeed true. □

Proposition 2.18. *The intersection of any set and the empty set as well as the intersection of the empty set and any set is empty, that is,*

$$\forall A\,(A \cap \emptyset = \emptyset \wedge \emptyset \cap A = \emptyset). \tag{2.62}$$

Proof. Letting A be an arbitrary set, we prove the first part of the conjunction by verifying

$$\forall y\,(y \notin A \cap \emptyset). \tag{2.63}$$

To do this, we take an arbitrary y and apply a proof by contradiction, assuming $y \in A \cap \emptyset$ to be true. This assumption implies the conjunction $y \in A \wedge y \in \emptyset$ with (2.57) and thus in particular $y \in \emptyset$. Since $y \notin \emptyset$ is also true according to (2.40), we obtained a contradiction according to (1.11), completing the proof of $y \notin A \cap \emptyset$. As y was arbitrary, we therefore conclude that (2.63) holds, which then further implies the desired equation $A \cap \emptyset = \emptyset$ by definition of the empty set.

To prove the second part of the conjunction in (2.62), we observe the truth of the equation

$$\emptyset \cap A = A \cap \emptyset \ (= \emptyset)$$

in light of the Commutative Law for the intersection of two sets, so that $\emptyset \cap A = \emptyset$ also holds. Since A was arbitrary, the proposed universal sentence (2.62) follows then to be true. □

Clearly, replacing the variable A in the preceding proposition by the constant $\emptyset$ gives the following equation.

Corollary 2.19. *The intersection of the empty set and the empty set is also empty, that is,*

$$\emptyset \cap \emptyset = \emptyset. \tag{2.64}$$

Since it happens frequently that the intersection of two given sets is empty, the following definition will be useful.

Definition 2.9 (Disjoint sets). We say that sets A and B are *disjoint* iff the intersection of the two sets is empty, that is, iff

$$A \cap B = \emptyset. \tag{2.65}$$

Corollary 2.20. *Any disjoint sets A and B where A is nonempty are distinct sets, that is,*

$$\forall A, B \, (A \neq \emptyset \Rightarrow [A \cap B = \emptyset \Rightarrow A \neq B]). \tag{2.66}$$

Proof. Letting A and B be arbitrary sets such that A is nonempty, we use the Law of Contraposition to prove the implication $A \cap B = \emptyset \Rightarrow A \neq B$, by assuming $\neg A \neq B$ to be true and by demonstrating that $A \cap B \neq \emptyset$ also holds. The preceding assumption implies now $A = B$ with the Double Negation Law, so that we obtain

$$A \cap B = A \cap A = A \quad (\neq \emptyset)$$

by applying substitution and the Idempotent Law for the intersection of two sets (and recalling the initial assumption $A \neq \emptyset$). We thus find $A \cap B \neq \emptyset$, as desired. Since A and B are arbitrary, we may infer from this finding the truth of the stated universal sentence. □

Proposition 2.21. *If two sets A and B are disjoint and if a set C is included in B, then A and C are also disjoint, that is,*

$$\forall A, B, C\,([A \cap B = \emptyset \,\wedge\, C \subseteq B] \Rightarrow A \cap C = \emptyset). \tag{2.67}$$

Proof. Letting A, B and C be arbitrary sets, we assume the equation $A \cap B = \emptyset$ and the inclusion $C \subseteq B$ to be true. Thus,

$$\forall y\,(y \notin A \cap B) \tag{2.68}$$

holds by definition of the empty set, and

$$\forall y\,(y \in C \Rightarrow y \in B) \tag{2.69}$$

holds by definition of a subset. We use the former definition also to establish now $A \cap C = \emptyset$, by verifying according the universal sentence

$$\forall y\,(y \notin A \cap C). \tag{2.70}$$

We let y be arbitrary, and we prove the negation $y \notin A \cap C$ by establishing the contradiction

$$y \in A \cap B \,\wedge\, y \notin A \cap B, \tag{2.71}$$

assuming the negation of $y \notin A \cap C$ to be true. Then, $y \in A \cap C$ follows to be true with the Double Negation Law. Consequently, the definition of the intersection of two sets gives us $y \in A$ and $y \in C$. The latter implies with (2.69) $y \in B$, and since $y \in A$ is also true, we thus find $y \in A \cap B$ (using again the definition of the intersection of two sets). Because y satisfies also $y \notin A \cap B$ in view of (2.68), we arrived at the desired contradiction (2.71). We thus proved $y \notin A \cap C$, so that the equivalent $A \cap C = \emptyset$ is also true. This finding in turn proves the implication in (2.67), in which the sets A, B and C are arbitrary. We may therefore conclude that the proposed universal holds. □

The Associative Law for sentences regarding the conjunction constitutes the foundation for the following

Theorem 2.22 (Associative Law for the intersection of two sets). *The intersection of two sets is associative in the sense that*

$$\forall A, B, C\,(A \cap [B \cap C] = [A \cap B] \cap C). \tag{2.72}$$

Proof. We let A, B and C be arbitrary sets and verify first

$$\forall y\,(y \in A \cap [B \cap C] \Leftrightarrow y \in [A \cap B] \cap C). \tag{2.73}$$

Letting y be arbitrary, we now obtain the true equivalences

$$\begin{aligned} y \in A \cap [B \cap C] &\Leftrightarrow (y \in A \wedge y \in B \cap C) \\ &\Leftrightarrow (y \in A \wedge [y \in B \wedge y \in C]) \\ &\Leftrightarrow ([y \in A \wedge y \in B] \wedge y \in C) \\ &\Leftrightarrow (y \in A \cap B \wedge y \in C) \\ &\Leftrightarrow (y \in [A \cap B] \cap C) \end{aligned}$$

by applying (2.57), again (2.57) in connection with the Substitution Rule for conjunctions (1.22), the Associative Law for the conjunction, again (2.57) in connection with the Substitution Rule for conjunctions (1.23) and the Commutative Law for the conjunction, and finally again (2.57). Consequently, the equivalence in (2.73) follows to be true with the Substitution Rule for equivalences (1.29). Because y is arbitrary, we may therefore conclude that (2.73) is true, so that the desired equation $A \cap [B \cap C] = [A \cap B] \cap C$ also holds in view of the Equality Criterion for sets. Then, as A, B and C were also arbitrary, it follows that the proposed universal sentence (2.72) is true, as claimed. □

Proposition 2.23. *The intersection of two sets is included in each of the two sets, i.e.*

$$\forall A, B\, (A \cap B \subseteq A \wedge A \cap B \subseteq B). \tag{2.74}$$

Proof. We let A and B be arbitrary sets and first observe the truth of the disjunction

$$A \cap B = \emptyset \vee A \cap B \neq \emptyset.$$

In the first case that $A \cap B = \emptyset$ is true, we notice that $\emptyset \subseteq A$ and $\emptyset \subseteq B$ because of (2.43). Therefore, substitution based on the preceding equation yields the inclusions $A \cap B \subseteq A$ and $A \cap B \subseteq B$, so that the conjunction in (2.74) is true in the first case.

In the second case that $A \cap B \neq \emptyset$ is true, we now see that there exists an element in $A \cap B$, according to (2.42). Let us next observe that the conjunction in (2.74) is equivalent to

$$\forall y\, (y \in A \cap B \Rightarrow y \in A) \wedge \forall y\, (y \in A \cap B \Rightarrow y \in B)$$

because of the definition of a subset and the Substitution Rules for conjunctions. Then, this conjunction is also equivalent to

$$\forall y\, ([y \in A \cap B \Rightarrow y \in A] \wedge [y \in A \cap B \Rightarrow y \in B])$$

according to the Distributive Law for quantification (1.74), and moreover equivalent to

$$\forall y\, (y \in A \cap B \Rightarrow [y \in A \wedge y \in B]) \tag{2.75}$$

due to the Distributive Law for sentences (1.46). To prove this universal sentence, we let y be arbitrary. We may now prove the implication directly, assuming $y \in A \cap B$ to be true, since $A \cap B$ is not empty in the current second case. Then, the assumed antecedent $y \in A \cap B$ immediately implies the truth of the consequent $y \in A \wedge y \in B$ by definition of the intersection of two sets. As y is arbitrary, we may therefore conclude that (2.75) holds, which in turn implies the truth of the equivalent conjunction in (2.74) also for the second case.

Since A and B were arbitrary sets, it then follows that the proposed universal sentence (2.74) holds. □

Exercise 2.2. Establish the following universal sentence.

$$\forall A, B, C \, (B \subseteq C \Rightarrow A \cap B \subseteq A \cap C). \tag{2.76}$$

(Hint: Use the definition of a subset in connection with the definition of the intersection of two sets.)

Proposition 2.24. *The intersection of a set B with a subset of B is identical with that subset, that is,*

$$\forall A, B \, (A \subseteq B \Rightarrow A \cap B = A). \tag{2.77}$$

Proof. We let A and B be arbitrary and prove the implication by cases.

In the first case, we assume $A \subseteq B \wedge A = \emptyset$ to be true, which implies in particular $A = \emptyset$ and therefore

$$A \cap B = \emptyset \cap B = \emptyset$$

by applying substitution and (2.62). These equations yield $A \cap B = \emptyset$ and then the desired $A \cap B = A$ via substitution.

In the second case, we assume now that $A \subseteq B \wedge A \neq \emptyset$ holds. The second part of this conjunction shows in light of (2.42) that there exists an element in A, say $\bar{y}$. Since the first part $A \subseteq B$ of the assumed conjunction means by definition of a subset that

$$\forall y \, (y \in A \Rightarrow y \in B) \tag{2.78}$$

holds, we have that $\bar{y} \in A$ implies $\bar{y} \in B$. Thus, the conjunction $\bar{y} \in A \wedge \bar{y} \in B$ holds, which in turn implies $\bar{y} \in A \cap B$ by definition of the intersection of two sets, so that there exists an element in the intersection $A \cap B$. Based on these findings, we now verify

$$\forall y \, (y \in A \cap B \Leftrightarrow y \in A), \tag{2.79}$$

by letting y be arbitrary and by proving both parts of the equivalence directly. Regarding the first part ('$\Rightarrow$'), we may assume $y \in A \cap B$ (recalling that $A \cap B$ is not empty), and therefore $y \in A$ follows in particular to be true by definition of the intersection of two sets. Regarding the second part ('$\Leftarrow$'), we may now assume $y \in A$ to be true (since A is also nonempty), which then implies $y \in B$ with (2.78). Therefore, the conjunction $y \in A \wedge y \in B$ is also true, which now gives $y \in A \cap B$ (using again the definition of the intersection of two sets). This completes the proof of the equivalence in (2.79), and since y is arbitrary, we therefore conclude that (2.79) holds.

This universal sentence in turn implies $A \cap B = A$ with the Equality Criterion for sets, completing the proof of the implication in (2.77) by cases. As A and B were arbitrary, we may now finally conclude that the proposed sentence is true. □

Proposition 2.25. *If a set A is included in a set C and a set B included in a set D, then the intersection of the two subsets A and B is included in the intersection of C and D, that is,*

$$\forall A, B, C, D\,([A \subseteq C \wedge B \subseteq D] \Rightarrow A \cap B \subseteq C \cap D). \tag{2.80}$$

Proof. We let A, B, C and D be arbitrary sets and prove the implication directly, assuming that the conjunction of $A \subseteq C$ and $B \subseteq D$ holds. We now prove the inclusion $A \cap B \subseteq C \cap D$ by verifying the equivalent (using the definition of a subset)

$$\forall y\,(y \in A \cap B \Rightarrow y \in C \cap D). \tag{2.81}$$

Letting y be arbitrary, we assume that $y \in A \cap B$ holds, so that $y \in A$ and $y \in B$ follow to be both true by definition of the intersection of two sets. We notice in light of the definition of a subset that the initial assumptions $A \subseteq C$ and $B \subseteq D$ are equivalent to, respectively,

$$\forall y\,(y \in A \Rightarrow y \in C) \tag{2.82}$$

and

$$\forall y\,(y \in B \Rightarrow y \in D). \tag{2.83}$$

Thus, the previously established $y \in A$ implies $y \in C$ with (2.82), and $y \in B$ implies $y \in D$ with (2.83). Since $y \in C$ and $y \in D$ are both true, it follows (again by definition of the intersection of two sets) that $y \in C \cap D$ holds, proving the implication in (2.81).

As y is arbitrary, we may therefore conclude that the universal sentence (2.81) holds, which then further implies $A \cap B \subseteq C \cap D$ by definition of a subset. This in turn proves the implication in (2.80), and since A, B, C and D were arbitrary, we may finally conclude that the proposition is true. □

Corollary 2.26. *If a set A is subset both of a set C and a set D, then A is subset of the intersection of C and D, that is,*

$$\forall A, C, D\,([A \subseteq C \,\wedge\, A \subseteq D] \Rightarrow A \subseteq C \cap D). \tag{2.84}$$

Proof. Letting A, C and D be arbitrary and assuming $A \subseteq C \,\wedge\, A \subseteq D$ to be true, it follows with (2.80) that $A \cap A \subseteq C \cap D$ holds. Since $A \cap A$ is identical with A according to the Idempotent Law for the intersection of two sets, substitution yields the desired $A \subseteq C \cap D$. As A, C and D were arbitrary, we may therefore conclude that (2.84) is true. □

Exercise 2.3. Show that if two sets A and B are both included in a set C, then the intersection of A and B is also included in X, that is,

$$\forall A, B, C\,([A \subseteq C \,\wedge\, B \subseteq C] \Rightarrow A \cap B \subseteq C). \tag{2.85}$$

Proposition 2.27. *If a nonempty set A and a set B are disjoint, then A is not included in B, that is,*

$$\forall A, B\,([A \neq \emptyset \,\wedge\, A \cap B = \emptyset] \Rightarrow \neg A \subseteq B). \tag{2.86}$$

Proof. We let A and B be arbitrary sets and prove then the implication by contradiction, assuming $A \neq \emptyset$, $A \cap B = \emptyset$ and $\neg(\neg A \subseteq B)$ to be true. The latter implies $A \subseteq B$ with the Double Negation Law and then

$$\forall y\,(y \in A \Rightarrow y \in B) \tag{2.87}$$

by definition of a subset. Furthermore, the initial assumption $A \neq \emptyset$ implies with (2.42) that there exists an element in A, say $\bar{y}$. Now, $\bar{y} \in A$ further implies $\bar{y} \in B$ with (2.87), so that $\bar{y} \in A$ and $\bar{y} \in B$ are both true. Consequently, $\bar{y} \in A \cap B$ holds by definition of the intersection of two sets, so that the existential sentence $\exists y\,(y \in A \cap B)$ is true, which then yields $A \cap B \neq \emptyset$ with (2.42). As we assumed $A \cap B = \emptyset$ to be also true, we evidently obtained a contradiction, which proves the implication in (2.86). Since A and B were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

The idea of specifying the intersection to two sets is readily generalized to the intersection of an arbitrary (nonempty) system of sets.

Theorem 2.28. *The following sentences are true for any set system $\mathcal{S} \neq \emptyset$ and any set $\bar{A} \in \mathcal{S}$.*

a) *There exists a unique set $\bigcap \mathcal{S}$ such that an element y is in $\bigcap \mathcal{S}$ iff y is element of $\bar{A}$ and moreover element of all sets in $\mathcal{S}$, i.e.*

$$\exists! \bigcap \mathcal{S}\, \forall y\,(y \in \bigcap \mathcal{S} \Leftrightarrow [y \in \bar{A} \,\wedge\, \forall A\,(A \in \mathcal{S} \Rightarrow y \in A)]). \tag{2.88}$$

b) The set $\bigcap \mathcal{S}$ *satisfies also*

$$\forall y\,(y \in \bigcap \mathcal{S} \Leftrightarrow \forall A\,(A \in \mathcal{S} \Rightarrow y \in A)). \tag{2.89}$$

Proof. We let $\mathcal{S}$ be an arbitrary set system and assume then that $\mathcal{S} \neq \emptyset$ holds, so that there exists an element in the set system $\mathcal{S}$, according to (2.42). We now let $\bar{A} \in \mathcal{S}$ be arbitrary.

Concerning a), we now define $\varphi(y)$ to be the formula

$$\forall A\,(A \in \mathcal{S} \Rightarrow y \in A).$$

Then, we may apply the Axiom of Specification to obtain the true existential sentence

$$\exists \bigcap \mathcal{S}\, \forall y\,(y \in \bigcap \mathcal{S} \Leftrightarrow [y \in \bar{A} \,\wedge\, \varphi(y)]),$$

which proves the existential part regarding the uniquely existential sentence (2.88). The uniqueness part is established by applying the Equality Criterion for sets. Thus, the proof of the uniquely existential sentence (2.88) is complete, and a) is therefore true.

Concerning b), we let y be arbitrary and observe in light of (2.88) that the set $\bigcap \mathcal{S}$ and y satisfy

$$y \in \bigcap \mathcal{S} \Leftrightarrow [y \in \bar{A} \,\wedge\, \forall A\,(A \in \mathcal{S} \Rightarrow y \in A)]. \tag{2.90}$$

To prove the first part ('$\Rightarrow$') of the equivalence in (2.89) directly, we now assume $y \in \bigcap \mathcal{S}$ to be true, which implies with (2.90) in particular the universal sentence with respect to A in (2.89), as desired. Thus, the proof of the first part of the equivalence in (2.89) is complete. To prove the second part ('$\Leftarrow$'), we assume that

$$\forall A\,(A \in \mathcal{S} \Rightarrow y \in A)$$

is true and observe in view of the previously established $\bar{A} \in \mathcal{S}$ that this gives $y \in \bar{A}$. Thus, the conjunction in (2.90) holds, so that $y \in \bigcap \mathcal{S}$ follows to be true, which already proves the second part of the equivalence in (2.89). Since y is arbitrary, we may therefore conclude that the set $\bigcap \mathcal{S}$ satisfies the universal sentence (2.89).

As the set $\mathcal{S}$ was arbitrary in the proof of a) and b), the theorem follows then to be true. $\square$

Exercise 2.4. Prove the uniqueness part of (2.88).

(Hint: Proceed in analogy to the proof of (2.50).)

Since it is clear from the preceding proposition that $\bigcap \mathcal{S}$ represents the uniquely specified set with the characteristic definite property (2.89), we provide a simplified form of definition.

Definition 2.10 (Intersection of a set system). For any set system $\mathcal{S} \neq \emptyset$ we call the set $\bigcap \mathcal{S}$ consisting of those elements which are in all sets in $\mathcal{S}$, in the sense that

$$\forall y\,(y \in \bigcap \mathcal{S} \Leftrightarrow \forall A\,(A \in \mathcal{S} \Rightarrow y \in A)),$$

the *intersection of* $\mathcal{S}$. This set is also symbolized by

$$\bigcap_{A \in \mathcal{S}} A \quad \text{or} \quad \{y : \forall A\,(A \in \mathcal{S} \Rightarrow y \in A)\}. \tag{2.91}$$

Proposition 2.29. *The intersection of a set system $\mathcal{S}$ is included in all of the sets in $\mathcal{S}$, that is,*

$$\forall \mathcal{S}, A\,(A \in \mathcal{S} \Rightarrow \bigcap \mathcal{S} \subseteq A)). \tag{2.92}$$

Proof. We let $\mathcal{S}$ be an arbitrary set system, we let A be an arbitrary set, and we assume that $A \in \mathcal{S}$ is true. To show that this implies $\bigcap \mathcal{S} \subseteq A$, we verify

$$\forall y\,(y \in \bigcap \mathcal{S} \Rightarrow y \in A). \tag{2.93}$$

Letting y be arbitrary, we assume $y \in \bigcap \mathcal{S}$ to be true, which assumption implies with (2.89) that

$$\forall A\,(A \in \mathcal{S} \Rightarrow y \in A)$$

holds. Therefore, the initially assumed $A \in \mathcal{S}$ implies $y \in A$, proving the implication in (2.93). As y is arbitrary, we may therefore conclude that (2.93) is true, which means $\bigcap \mathcal{S} \subseteq A$ by definition of a subset. This in turn proves the implication in (2.92), and since A was also arbitrary, we may then further conclude that (2.92) holds. Finally, because $\mathcal{S}$ and $\bar{A}$ were arbitrary, the proposed sentence follows then to be true. □

Definition 2.11 (System of pairwise disjoint sets, pairwise disjoint sets). We say for any set system $\mathcal{S}$ that $\mathcal{S}$ is a *system of pairwise disjoint sets* (alternatively, that $\mathcal{S}$ has *pairwise disjoint sets*) iff any two distinct sets in $\mathcal{S}$ are disjoint, i.e. iff

$$\forall A, B\,([A, B \in \mathcal{S} \land A \neq B] \Rightarrow A \cap B = \emptyset). \tag{2.94}$$

2.4. Set Differences

Another straightforward utilization of the Axiom of Specification in combination with the Equality Criterion for sets consists in the definition of a unique set which contains precisely every element which is in a given set A but not in another set B.

Theorem 2.30. *For any sets A and B there exists a unique set $A \setminus B$ such that an element y is in $A \setminus B$ iff y is element of A and not element of B, i.e.*

$$\exists! A \setminus B \, \forall y \, (y \in A \setminus B \Leftrightarrow [y \in A \, \wedge \, y \notin B]). \tag{2.95}$$

Exercise 2.5. Prove Theorem 2.30.

(Hint: Proceed in analogy to the proof of Theorem 2.15.)

Definition 2.12 (Set difference). For any sets A and B we call the set $A \setminus B$ containing precisely all elements in A which are not in B, in the sense that

$$\forall y \, (y \in A \setminus B \Leftrightarrow [y \in A \, \wedge \, y \notin B]), \tag{2.96}$$

the *set difference* of A and B. This set is also symbolized by

$$\{y : y \in A \, \wedge \, y \notin B\}. \tag{2.97}$$

The definition of the difference of two sets now gives rise to a variety of useful relationships with the previously established types of sets. We begin with two basic results

Proposition 2.31. *The set difference of a set A and a set B is identical with the set difference of A and the intersection of A and B, that is,*

$$\forall A, B \, (A \setminus B = A \setminus [A \cap B]). \tag{2.98}$$

Proof. Letting A and B be arbitrary sets, we verify

$$\forall y \, (y \in A \setminus B \Leftrightarrow y \in A \setminus [A \cap B]). \tag{2.99}$$

Letting y be arbitrary, we obtain the true equivalences

$$\begin{aligned}
y \in A \setminus (A \cap B) &\Leftrightarrow y \in A \, \wedge \, \neg y \in A \cap B \\
&\Leftrightarrow y \in A \, \wedge \, \neg(y \in A \, \wedge \, y \in B) \\
&\Leftrightarrow y \in A \, \wedge \, (y \notin A \, \vee \, y \notin B) \\
&\Leftrightarrow (y \in A \, \wedge \, y \notin A) \, \vee \, (y \in A \, \wedge \, y \notin B) \\
&\Leftrightarrow y \in A \, \wedge \, y \notin B \\
&\Leftrightarrow y \in A \setminus B
\end{aligned}$$

using the definition of a set difference together with Definition 2.1 concerning $\notin$, the definition of the intersection of two sets, De Morgan's Law for sentences (1.51), the Distributive Law for sentences (1.44), (1.15) together with the fact that $y \in A \wedge y \notin A$ is a contradiction as in (1.11), and finally again the definition of a set difference. As y is arbitrary, we may therefore conclude that (2.99) is true, which in turn implies the equation in (2.98) with the Equality Criterion of sets. Since A and B are also arbitrary, we may finally conclude that the universal sentence (2.98) holds. □

The following exercise shows that the definitions of the intersection of two sets and of the set difference are in a certain sense compatible, since both are specified in terms of a conjunction.

Exercise 2.6. Verify that the intersection of a set A with the set difference of a set B and a set C can be written as the set difference of the intersection of A with B and C, that is,

$$\forall A, B, C\,(A \cap [B \setminus C] = [A \cap B] \setminus C). \tag{2.100}$$

(Hint: Proceed similarly as in the proof of Proposition 2.31, and apply in particular (1.39).)

Proposition 2.32. *The pairwise intersection is distributive over the set difference in the sense that*

$$\forall A, B, C\,(A \cap [B \setminus C] = [A \cap B] \setminus [A \cap C]). \tag{2.101}$$

Proof. Letting A, B and C be arbitrary, we obtain for an arbitrary y the true equivalences

$$\begin{aligned}
y \in (A \cap B) \setminus (A \cap C) &\Leftrightarrow y \in A \cap B \,\wedge\, y \notin A \cap C \\
&\Leftrightarrow (y \in A \,\wedge\, y \in B) \,\wedge\, \neg(y \in A \,\wedge\, y \in C) \\
&\Leftrightarrow (y \in A \,\wedge\, y \in B) \,\wedge\, (y \notin A \,\vee\, y \notin C) \\
&\Leftrightarrow ([y \in A \,\wedge\, y \in B] \,\wedge\, y \notin A) \\
&\qquad \vee\, ([y \in A \,\wedge\, y \in B] \,\wedge\, y \notin C) \\
&\Leftrightarrow (y \in B \,\wedge\, [y \in A \,\wedge\, y \notin A]) \\
&\qquad \vee\, (y \in A \,\wedge\, [y \in B \,\wedge\, y \notin C]) \\
&\Leftrightarrow (y \in A \,\wedge\, [y \in B \,\wedge\, y \notin C]) \\
&\Leftrightarrow y \in A \,\wedge\, y \in B \setminus C \\
&\Leftrightarrow y \in A \cap (B \setminus C)
\end{aligned}$$

using the definition of a set difference, the definition of the intersection of two sets, De Morgan's Law for the conjunction, the Distributivity of the conjunction over the disjunction, the Commutative Law for the intersection together with the Associative Law for the intersection, then the Contradiction Law with the fact that $y \in A \wedge y \notin A$ is a contradiction and consequently also $y \in B \wedge [y \in A \wedge y \notin A]$, subsequently the definition of a set difference, and finally the definition of the intersection of two sets. Because y is arbitrary, we may apply the Equality Criterion for sets to infer from the truth of the preceding equivalences the truth of the equation in (2.101). Since A, B and C are also arbitrary, we may therefore conclude that the proposed universal sentence holds. □

2.4.1. Basic relationships of set differences with the empty set

Proposition 2.33. *The difference of a set and the empty set is the set itself, that is,*

$$\forall A\,(A \setminus \emptyset = A). \tag{2.102}$$

Proof. Letting A be an arbitrary set, we apply the Equality Criterion for sets and prove the equation by verifying the equivalent

$$\forall y\,(y \in A \setminus \emptyset \Leftrightarrow y \in A). \tag{2.103}$$

For this purpose, we let y be arbitrary and observe that $y \in A \setminus \emptyset$ is equivalent to the conjunction $y \in A \wedge y \notin \emptyset$ according to (2.96). Since $y \notin \emptyset$ is a tautology by definition of the empty set, the preceding conjunction is equivalent to $y \in A$ because of (1.13). Consequently, $y \in A \setminus \emptyset$ is equivalent to $y \in A$, and since y is arbitrary, we may therefore conclude that the universal sentence (2.103) holds, which gives the equation $A \setminus \emptyset = A$ with the Equality Criterion for sets. Because the set A was also arbitrary, we may then further conclude that the proposed universal sentence (2.102) is also true. □

Exercise 2.7. Show for any set A that

a) the difference of A and A itself is empty, that is,

$$\forall A\,(A \setminus A = \emptyset). \tag{2.104}$$

b) the difference of the empty set and A is empty, that is,

$$\forall A\,(\emptyset \setminus A = \emptyset). \tag{2.105}$$

(Hint: Take the same approach as in the proof of Proposition 2.18, using (2.39) and (2.96).)

Exercise 2.8. Show for any sets A and B that the set difference of A and B and the set difference of B and A are disjoint, that is,

$$\forall A, B\,([A \setminus B] \cap [B \setminus A] = \emptyset). \tag{2.106}$$

Proposition 2.34. *Two sets A and B are disjoint iff the set difference of A and B is identical with A, that is,*

$$\forall A, B\,(A \cap B = \emptyset \Leftrightarrow A \setminus B = A). \tag{2.107}$$

Proof. We let A and B be arbitrary sets and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $A \cap B = \emptyset$ to be true, which equation implies by definition of the empty set

$$\forall y\,(y \notin A \cap B). \tag{2.108}$$

To establish the truth of $A \setminus B = A$, we apply the Equality Criterion for sets and prove the equivalent

$$\forall y\,(y \in A \setminus B \Leftrightarrow y \in A). \tag{2.109}$$

For this purpose, we take an arbitrary y, so that $\neg y \in A \cap B$ holds in view of (2.108). This negation further implies $\neg(y \in A \wedge y \in B)$ with the definition of the intersection of two sets, and then De Morgan's Law for sentences (1.51) gives the true disjunction

$$y \notin A \vee y \notin B. \tag{2.110}$$

In case that $y \notin A$ holds, we have that $y \in A$ is false, and the conjunction of $y \in A$ and $y \notin B$ is then also false. In light of the definition of a set difference, we now see that $y \in A \cap B$ is false. Together with the false $y \in A$, this shows that both sides of the equivalence in (2.109) are false, so that the equivalence itself is true.

In case that the second part $y \notin B$ of the disjunction (2.110) holds, we notice that the conjunction $y \in A \wedge y \notin B$ is equivalent to $y \in A$ because of (1.13) in connection with the fact that $y \notin B$ is then a tautology. Since $y \in A \setminus B$ is equivalent to $y \in A \wedge y \notin B$ (by definition of a set difference), it follows with the Substitution Rule for equivalences (1.29) that $y \in A \setminus B$ is equivalent to A.

Thus, the equivalence in (2.109) holds in any case, and as y was arbitrary, we therefore conclude that (2.109) is true. This universal sentence yields then $A \setminus B = A$ with the Equality Criterion for sets, so that the proof of the first part of the equivalence in (2.107) is complete.

We now prove the second part ('$\Leftarrow$') of the equivalence by contradiction, assuming $A \setminus B = A$ and $A \cap B \neq \emptyset$ to be true. The former assumption implies (2.109) again with the Function Criterion for sets, and the latter assumption implies with (2.42) that there exists an element in $A \cap B$, say $\bar{y}$. Here, $\bar{y} \in A \cap B$ means (by definition of the intersection of two sets) that $\bar{y} \in A$ and $\bar{y} \in B$ are both true. Let us now observe that (2.109) yields the true equivalence

$$\bar{y} \in A \setminus B \Leftrightarrow \bar{y} \in A.$$

Because $\bar{y} \in A$ is true, the left-hand side $\bar{y} \in A \setminus B$ of this equivalence also holds, which means (by definition of a set difference) that $\bar{y} \in A$ and $\bar{y} \notin B$ are both true. The latter contradicts the previously established $\bar{y} \in B$, which completes the proof of the second part of the equivalence in (2.107). Since A and B were arbitrary, we may therefore conclude that the proposed universal sentence holds, as claimed. □

We will occasionally apply the following lemma as a tool to turn two given sets A and B into disjoint sets by removing all the elements from B which are in A.

Lemma 2.35 (Generation of two disjoint sets). *Any set A and the difference of a set B and A are disjoint, that is,*

$$\forall A, B\,(A \cap [B \setminus A] = \emptyset). \tag{2.111}$$

Proof. We let A and B be arbitrary sets and prove

$$\forall y\,(y \notin A \cap [B \setminus A]). \tag{2.112}$$

Letting y be arbitrary, we now obtain the equivalences

$$\begin{aligned} y \in A \cap [B \setminus A] &\Leftrightarrow y \in A \wedge y \in B \setminus A \\ &\Leftrightarrow y \in A \wedge (y \in B \wedge \neg y \in A) \\ &\Leftrightarrow y \in A \wedge (\neg y \in A \wedge y \in B) \\ &\Leftrightarrow (y \in A \wedge \neg y \in A) \wedge y \in B, \end{aligned}$$

using the definition of the intersection of two sets, the definition of a set difference, the Commutative Law for sentences (1.36), and the Associative Law for sentences (1.39). Since $y \in A \wedge \neg y \in A$ is a contradiction as in (1.11), the multiple conjunction on the right-hand side is false. Consequently, the left-hand side $y \in A \cap (B \setminus A)$ is also false. Thus, the negation $y \notin A \cap [B \setminus A]$ is true, and since y is arbitrary, we may therefore conclude that (2.112) holds. This universal sentence then implies $A \cap [B \setminus A] = \emptyset$ by definition of the empty set, and as A and B were arbitrary sets, we may finally conclude that the proposed universal sentence (2.111) is true. □

Proposition 2.36. *If a set A is not included in a set B, then the set difference of A and B is nonempty, that is,*

$$\forall A, B\,(\neg A \subseteq B \Rightarrow A \setminus B \neq \emptyset). \tag{2.113}$$

Proof. We let A and B be arbitrary sets and observe the truth of the equivalences

$$\begin{aligned}
\neg A \subseteq B \;&\Leftrightarrow\; \neg\forall y\,(y \in A \Rightarrow y \in B) \\
&\Leftrightarrow\; \neg\forall y\,(y \in A \Rightarrow \neg y \notin B) \\
&\Leftrightarrow\; \exists y\,(y \in A \,\wedge\, y \notin B) \\
&\Leftrightarrow\; \exists y\,(y \in A \setminus B) \\
&\Leftrightarrow\; A \setminus B \neq \emptyset,
\end{aligned}$$

using the definition of a subset, the Double Negation Law, (1.82), the definition of a set difference, and finally (2.42). Therefore, the equivalence in (2.113) holds. Since A and B are arbitrary, we therefore conclude that the proposed universal sentence is true. □

Note 2.12. The proof of Proposition 2.36 shows that, if a set A is not included in a set B, then there exists an element in the set difference of A and B, i.e., we may write (2.113) equivalently as

$$\forall A, B\,(\neg A \subseteq B \Rightarrow \exists y\,(y \in A \setminus B)). \tag{2.114}$$

Corollary 2.37. *If a nonempty set A and a set B are disjoint, then the set difference of A and B is nonempty, and thus there exists an element in the set difference of A and B, that is,*

$$\forall A, B\,([A \neq \emptyset \,\wedge\, A \cap B = \emptyset] \Rightarrow A \setminus B \neq \emptyset), \tag{2.115}$$

$$\forall A, B\,([A \neq \emptyset \,\wedge\, A \cap B = \emptyset] \Rightarrow \exists y\,(y \in A \setminus B)). \tag{2.116}$$

Proof. Letting A and B be arbitrary sets such that $A \neq \emptyset$ and $A \cap B = \emptyset$ are true, we obtain $\neg A \subseteq B$ with (2.86). This negation then implies on the one hand $A \setminus B \neq \emptyset$ with (2.113), and on the other hand $\exists y\,(y \in A \setminus B)$ with (2.114). As A and B were arbitrary, the proposed sentences then follow to be true. □

2.4.2. Basic relationships of set differences with subsets

Proposition 2.38. *If a set A is a subset of the set difference of two sets B and C, then A and C are disjoint sets, that is,*

$$\forall A, B, C\,(A \subseteq B \setminus C \Rightarrow A \cap C = \emptyset). \tag{2.117}$$

Proof. Letting A, B and C be arbitrary sets we now prove the implication by contradiction, assuming that $A \subseteq B \setminus C$ and $A \cap C \neq \emptyset$ are both true. The latter implies with (2.42) that there exists an element in $A \cap C$, say $\bar{y}$. This in turn implies by definition of the intersection of two sets that $y \in A$ and $y \in C$ are both true. The former implies $y \in B \setminus C$ with the assumption $A \subseteq B \setminus C$ and the definition of a subset, so that $y \in B$ and $y \notin C$ are true by definition of a set difference. Here, $y \notin C$ contradicts the previously established $y \in C$, which completes the proof by contradiction of the implication in (2.117). Since A, B and C are arbitrary, we therefore conclude that the proposition is true. □

Exercise 2.9. Prove that the difference of a set A and a set B is empty if A is included in B, that is,

$$\forall A, B\, (A \subseteq B \Rightarrow A \setminus B = \emptyset). \tag{2.118}$$

(Hint: Proceed similarly as in the proof of Proposition 2.38.)

Exercise 2.10. Show that, if two sets B and C are disjoint and if, then any subset of B and the set C are also disjoint, that is,

$$\forall A, B, C\, ([B \cap C = \emptyset \ \wedge\ A \subseteq B] \Rightarrow A \cap C = \emptyset). \tag{2.119}$$

(Hint: Prove the implication by contradiction, using (2.42).)

Proposition 2.39. *Any subset A of a set B is identical with the difference of B and the difference of B and A, that is,*

$$\forall A, B\, (A \subseteq B \Rightarrow B \setminus [B \setminus A] = A). \tag{2.120}$$

Proof. We let A and B be arbitrary sets, assume $A \subseteq B$, and apply the Equality Criterion for sets to prove the stated equation, by verifying the equivalent universal sentence

$$\forall y\, (y \in B \setminus [B \setminus A] \Leftrightarrow y \in A). \tag{2.121}$$

For this purpose, we let y be arbitrary and observe the truth of the equivalences

$$\begin{aligned}
y \in B \setminus [B \setminus A] \ &\Leftrightarrow\ y \in B \ \wedge\ \neg y \in B \setminus A \\
&\Leftrightarrow\ y \in B \ \wedge\ \neg(y \in B \ \wedge\ y \notin A) \\
&\Leftrightarrow\ y \in B \ \wedge\ (y \notin B \ \vee\ \neg y \notin A) \\
&\Leftrightarrow\ (y \in B \ \wedge\ y \notin B) \ \vee\ (y \in B \ \wedge\ y \in A) \\
&\Leftrightarrow\ y \in B \ \wedge\ y \in A \\
&\Leftrightarrow\ y \in B \cap A \\
&\Leftrightarrow\ y \in A \cap B \\
&\Leftrightarrow\ y \in A
\end{aligned}$$

in light of the definition of a set difference (twice), De Morgan's Law for sentences (1.51), the Distributive Law for sentences (1.44) together with the Double Negation Law, (1.15) in connection with the fact that $y \in B \land y \notin B$ constitutes a contradiction according to (1.11), the definition of the intersection of two sets, the Commutative Law for the intersection of two sets, and finally substitution based on the equation $A \cap B = A$ implied by the initially assumed inclusion $A \subseteq B$ with (2.77). Consequently, the equivalence in (2.121) is true, and since y is arbitrary, we may therefore conclude that (2.121) holds. This universal sentence in turn implies the desired equation $B \setminus [B \setminus A] = A$ with the Equality Criterion for sets. This proves the implication in (2.120), and as A and B were arbitrary, we therefore conclude that the proposed universal sentence (2.120) holds, as claimed. □

Proposition 2.40. *If a set A is a subset of a set B, then the difference of a set C and B is included in the difference of C and A, that is,*

$$\forall A, B, C\,(A \subseteq B \Rightarrow C \setminus B \subseteq C \setminus A). \tag{2.122}$$

Proof. We let A, B and C be arbitrary, assume $A \subseteq B$, that is (applying the definition of a subset),

$$\forall y(y \in A \Rightarrow y \in B), \tag{2.123}$$

and show that this implies $C \setminus B \subseteq C \setminus A$, that is,

$$\forall y\,(y \in C \setminus B \Rightarrow y \in C \setminus A). \tag{2.124}$$

To do this, we let y be arbitrary and assume that the antecedent $y \in C \setminus B$ holds, which means by definition of a set difference that $y \in C$ and $y \notin B$ are both true. Let us now observe in view of (2.123) that the implication $y \in A \Rightarrow y \in B$ is true, so that its contraposition $y \notin B \Rightarrow y \notin A$ is also true (by the Law of Contraposition). With this, the previously established $y \notin B$ implies $y \notin A$. Thus, $y \in C$ and $y \notin A$ are both true, which means that $y \in C \setminus A$ holds. As y is arbitrary, we therefore conclude that (2.124) is true, so that $C \setminus B \subseteq C \setminus A$ holds. Since A, B and C were also arbitrary, it follows that the proposed universal sentence (2.122) is true. □

Exercise 2.11. Show that the difference of a set B and a set A is included in B, that is,

$$\forall A, B\,(B \setminus A \subseteq B). \tag{2.125}$$

(Hint: Proceed similarly as in the proof of Proposition 2.40.)

The result of this exercise immediately yields the following finding with the transitivity of $\subseteq$.

Corollary 2.41. *If a set B is included in a set C, then the difference of B and any set A is also included in C, that is,*

$$\forall A, B, C\,(B \subseteq C \Rightarrow B \setminus A \subseteq C). \tag{2.126}$$

Proof. Letting A, B and C be arbitrary sets such that $B \subseteq C$ holds, we first observe that $B \setminus A \subseteq B$ holds according to (2.125). Thus, the conjunction of $B \setminus A \subseteq B$ and $B \subseteq C$ is true, which in turn implies the desired inclusion $B \setminus A \subseteq C$ with (2.13). This proves the implication in (2.126), and since A, B and C were arbitrary, we may therefore conclude that the corollary is true. □

Proposition 2.42. *The difference of a set B and a proper subset of B is nonempty, that is,*

$$\forall A, B\,(A \subset B \Rightarrow B \setminus A \neq \emptyset). \tag{2.127}$$

Proof. We let A and B be arbitrary sets and prove the implication by contradiction, assuming that $A \subset B$ and $B \setminus A = \emptyset$ both hold. Here, the latter assumption implies with (2.41)

$$\neg \exists y\,(y \in B \setminus A), \tag{2.128}$$

and the former assumption that $A \subseteq B$ and $A \neq B$ are both true. Then, the former inclusion implies $A \setminus B = \emptyset$ with (2.118), and the latter inequality implies

$$\neg \forall y\,(y \in A \Leftrightarrow y \in B)$$

with (2.18). This negation further implies

$$\exists y\,(\neg[y \in A \Rightarrow y \in B] \;\vee\; \neg[y \in B \Rightarrow y \in A])$$

with the Quantifier Negation Law (1.53), (1.8) and De Morgan's Law (1.51), and then

$$\exists y\,(y \in A \,\wedge\, y \notin B) \,\vee\, \exists y\,(y \in B \,\wedge\, y \notin A)$$

with the Distributive Law for quantification (1.75) and the Conditional Law 1.32). This shows by definition of a set difference that $\exists y\,(y \in A \setminus B)$ or $\exists y\,(y \in B \setminus A)$ holds. The second part of this disjunction is false because of the truth of (2.128), so that the first part $\exists y\,(y \in A \setminus B)$ is true. This sentence implies $A \setminus B \neq \emptyset$ with (2.42), which evidently contradicts the previously established $A \setminus B = \emptyset$ according to (2.18). Thus, the proof of the implication in (2.127) is complete. Since A and B were arbitrary, it then follows that the proposed universal sentence is true. □

Proposition 2.43. *It is true that, if a nonempty set A is a proper subset of a nonempty set B, then the set difference of B and A is also a proper subset of B, that is,*

$$\forall A, B\,([A \neq \emptyset \land A \subset B] \Rightarrow B \setminus A \subset B). \tag{2.129}$$

Proof. We let A and B be arbitrary sets and consider the two cases $B = \emptyset$ and $B \neq \emptyset$. In the first case of $B = \emptyset$, we observe that (2.47) implies $\neg A \subset B$ with the Quantifier Negation Law (1.54). Thus, $A \subset B$ is false, so that the conjunction $A \neq \emptyset \land A \subset B$ is also false. Consequently, the implication in (2.129) is then true in the first case. In the second case of $B \neq \emptyset$, we may prove this implication directly, assuming that A is a nonempty, proper subset of B. To show that this implies $B \setminus A \subset B$, we first verify $B \setminus A \neq A$. For this purpose, we apply Exercise 2.1 and show that there exists an element y satisfying

$$(y \in B \setminus A \land y \notin B) \lor (y \in B \land y \notin B \setminus A). \tag{2.130}$$

Now, the initial assumption $A \neq \emptyset$ implies with (2.42) that there exists an element in A, say $\bar{y}$. Then, the disjunction $\bar{y} \notin B \lor \bar{y} \in A$ is also true, which we may write equivalently as $\neg(\bar{y} \in B \land \bar{y} \notin A)$ by applying De Morgan's Law (1.51) and the Double Negation Law. This negation means in connection with the definition of a set difference that $\bar{y} \notin B \setminus A$ holds. Furthermore, the initial assumption $A \subset B$ implies (by definition of a proper subset) in particular that $A \subseteq B$ is true. Therefore, the previously established $\bar{y} \in A$ implies $\bar{y} \in B$ with the definition of a subset, so that the conjunction $\bar{y} \in B \land \bar{y} \notin B \setminus A$ holds. Then, the disjunction

$$(\bar{y} \in B \setminus A \land \bar{y} \notin B) \lor (\bar{y} \in B \land \bar{y} \notin B \setminus A)$$

is also true, so that we proved the existence of an element y which satisfies (2.130). This existential sentence then implies with Exercise 2.1 that $B \setminus A \neq A$ holds. Since $B \setminus A \subseteq A$ is also true in view of (2.125), it follows from these findings by definition of a proper subset that the desired $B \setminus A \subset A$ holds. As A and B were arbitrary, we may therefore conclude that the proposed universal sentence (2.129) is true. □

In certain situations, there is a fundamental set X which includes all of the occurring sets. In such situations, it will be useful to have the following concept at out disposal.

Definition 2.13 (Complement). For any set X and any subset A of X we call

$$A^c = X \setminus A \tag{2.131}$$

the *complement of A with respect to X.*

Proposition 2.44. *For any set X and any subset B of X it is true that an element y of X is in the complement of B (with respect to X) iff y is not in B, that is,*

$$\forall X, B\,(B \subseteq X \Rightarrow \forall y\,(y \in X \Rightarrow [y \in B^c \Leftrightarrow y \notin B])). \tag{2.132}$$

Proof. Letting X and B be arbitrary, assuming $B \subseteq X$, and letting furthermore y be arbitrary in X, we see that $y \in B^c$ is by definition of a complement equivalent to $y \in X \setminus B$, which in turn is equivalent to $y \in X \wedge y \notin B$ by definition of a set difference. Since $y \in X$ is true and thus a tautology, the conjunction $y \in X \wedge y \notin B$ is equivalent to $y \notin B$ according to (1.13). Consequently, $y \in B^c$ is equivalent to $y \notin B$, and as y is arbitrary, we may therefore conclude that the universal sentence in (2.132) holds. Since X and B were also arbitrary, the universal sentence (2.132) follows then to be true. □

Exercise 2.12. Verify the following sentences for any set X.

a) The complement of the empty set with respect to X is identical with X, and the complement of X (with respect to X) is empty, i.e.

$$\emptyset^c = X, \tag{2.133}$$
$$X^c = \emptyset. \tag{2.134}$$

b) The intersection of a set A and its complement (with respect to X) is empty, i.e.

$$\forall A\,(A \subseteq X \Rightarrow A \cap A^c = \emptyset). \tag{2.135}$$

c) A set $A \subseteq X$ is identical with the complement of its complement, i.e.

$$\forall A\,(A \subseteq X \Rightarrow [A^c]^c = A). \tag{2.136}$$

d) The complement of a set $A \subseteq X$ is included in X, i.e.

$$\forall A\,(A \subseteq X \Rightarrow A^c \subseteq X). \tag{2.137}$$

(Hint: Apply Proposition 2.33, Exercise 2.7, Lemma 2.35, Proposition 2.39, and Exercise 2.11.)

We end this section with the demonstration of the useful fact that the set difference may be expressed by means of the complement and the intersection of two sets.

Theorem 2.45. *The intersection of the set A with the complement of the set B is equal to the set difference of A and B, that is,*

$$\forall X, A, B\,([A \subseteq X \;\wedge\; B \subseteq X] \Rightarrow A \setminus B = A \cap B^c). \tag{2.138}$$

Proof. Letting X, A and B be arbitrary sets and assuming $A \subseteq X$ as well as $B \subseteq X$ to be true, we first prove

$$\forall y\,(y \in A \setminus B \Leftrightarrow y \in A \cap B^c). \tag{2.139}$$

Letting y be arbitrary, we now obtain the true equivalences

$$\begin{aligned}
y \in A \cap B^c \;&\Leftrightarrow\; y \in A \;\wedge\; y \in B^c \\
&\Leftrightarrow\; y \in A \;\wedge\; y \in X \setminus B \\
&\Leftrightarrow\; y \in A \;\wedge\; (y \in X \;\wedge\; y \notin B) \\
&\Leftrightarrow\; y \in A \;\wedge\; (y \notin B \;\wedge\; y \in X) \\
&\Leftrightarrow\; (y \in A \;\wedge\; y \notin B) \;\wedge\; y \in X \\
&\Leftrightarrow\; (y \in A \setminus B) \;\wedge\; y \in X \\
&\Leftrightarrow\; y \in (A \setminus B) \cap X \\
&\Leftrightarrow\; y \in (A \setminus B)
\end{aligned}$$

by applying the definition of the intersection of two sets, the definition of a complement, the definition of a set difference, the Commutative Law for Sentences (1.36), the Associative Law for sentences (1.39), again the definition of a set difference, again the definition of the intersection of two sets, and finally (2.77) based the fact that the initially assumed $A \subseteq X$ implies $A \setminus B \subseteq X$ with (2.126). These equivalences evidently imply the truth of the equivalence in (2.139), and since y is arbitrary, it then follows that the universal sentence (2.139) also holds. Consequently, the Equality Criterion for sets gives the equation $A \setminus B = A \cap B^c$, which in turn proves the implication in (2.138). Finally, as X, A and B were also arbitrary, we conclude that the stated theorem is true. □

Corollary 2.46. *It is true for any subset A of a subset B of a set X that A and the complement of B (with respect to X) are disjoint, that is,*

$$\forall A, B, X\,([A \subseteq B \;\wedge\; B \subseteq X] \Rightarrow A \cap B^c = \emptyset). \tag{2.140}$$

Proof. Letting A, B and C be arbitrary sets such that A is included in B and such that B included in X, we obtain the inclusion $A \subseteq X$ with (2.13). Since the assumed inclusion $A \subseteq B$ implies with (2.118) $A \setminus B = \emptyset$, for which set difference the other two inclusions $A \subseteq X$ and $B \subseteq X$ imply

$A \setminus B = A \cap B^c$, we obtain the desired consequent $A \cap B^c = \emptyset$ of the implication in (2.140) via substitution. Here, the sets A, B and X were arbitrary, so that the corollary follows indeed to be true. □

Proposition 2.47. *For any disjoint sets A and B both included in a set X, it is true that A is included in the complement of B, that is,*

$$\forall A, B, X\,([A \subseteq X \,\wedge\, B \subseteq X \,\wedge\, A \cap B = \emptyset] \Rightarrow A \subseteq B^c). \tag{2.141}$$

Proof. We take arbitrary sets A, B and X such that $A \subseteq X$, $B \subseteq X$ and $A \cap B = \emptyset$ are all true. To establish the inclusion $A \subseteq B^c$, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall y\,(y \in A \Rightarrow y \in B^c). \tag{2.142}$$

We let y be arbitrary and assume $y \in A$ to be true, so that the assumed inclusion $A \subseteq X$ gives $y \in X$ (by definition of a subset). Since the disjointness assumption $A \cap B = \emptyset$ implies the negation $\neg y \in A \cap B$ by definition of the empty set, which implies the negation $\neg(y \in A \wedge y \in B)$ with the definition of the intersection of two sets, we obtain the true disjunction $y \notin A \vee y \notin B$ with De Morgan's Law for the conjunction. Because we assumed $y \in A$ to be true, so that the negation $y \notin A$ is false, the second part $y \notin B$ of the preceding disjunction is true. Consequently, the truth of $B \subseteq X$, of $y \in X$ and of $y \notin B$ implies with (2.132) the truth of $y \in B^c$, proving the implication in (2.142). Since y is arbitrary, we may therefore conclude that the universal sentence (2.142) is true, which then gives the desired inclusion $A \subseteq B^c$. This finding completes the proof of the implication in (2.141), and as A, B and X were initially arbitrary sets, we may now finally conclude that the proposed universal sentence is true. □

Exercise 2.13. Prove for any disjoint sets A and B both included in a set X that B is included in the complement of A^c, that is,

$$\forall A, B, X\,([A \subseteq X \,\wedge\, B \subseteq X \,\wedge\, A \cap B = \emptyset] \Rightarrow B \subseteq A^c). \tag{2.143}$$

2.5. Pairs and Singletons

We now introduce another axiom which will enable us to define a new type of set, which would not be possible with the axioms of specification and extension alone.

Axiom 2.3 (Axiom of pairing). For any a and any b there exists a set Z which contains a and b, that is,

$$\forall a, b \, \exists Z \, (a \in Z \wedge b \in Z). \tag{2.144}$$

As we intend to derive from this axiom a precise and unambiguous definition of a 'pair' of sets, we will in analogy to the establishment of the intersection of two sets and of the set difference exclude the possibility that this new set contains additional elements aside from a and b.

Theorem 2.48. *The following sentences are true for any a, b and any set Z containing a and b.*

a) There exists a unique set $\{a,b\}$ such that an element y is in $\{a,b\}$ iff y is in Z and moreover if y is identical with a or b, i.e.

$$\exists! \{a,b\} \, \forall y \, (y \in \{a,b\} \Leftrightarrow [y \in Z \wedge (y = a \vee y = b)]). \tag{2.145}$$

b) The set $\{a,b\}$ is nonempty, that is,

$$\{a,b\} \neq \emptyset. \tag{2.146}$$

c) The set $\{a,b\}$ satisfies also

$$\forall y \, (y \in \{a,b\} \Leftrightarrow [y = a \vee y = b]). \tag{2.147}$$

Proof. We let a and b be arbitrary and let Z an arbitrary set containing a and b (using the fact that such a set exists in view of the Axiom of Pairing).

Concerning a), we let $\varphi(y)$ be the formula

$$y = a \vee y = b.$$

Consequently, the Axiom of Specification yields the true existential sentence

$$\exists \{a,b\} \, \forall y \, (y \in \{a,b\} \Leftrightarrow [y \in Z \wedge \varphi(y)]),$$

so that the proof of the existential part of the uniquely existential sentence (2.145) is complete. We may prove the uniqueness part by means of the

Equality Criterion for sets. Now, the proof of the uniquely existential sentence (2.145) is complete, so that a) is true.

Concerning b), we let $\{a, b\}$ be the unique set satisfying

$$\forall y\,(y \in \{a,b\} \Leftrightarrow [y \in Z \wedge (y = a \vee y = b)]). \tag{2.148}$$

Next, we observe the truth of the equation $a = a$, so that the disjunction $a = a \vee a = b$ is also true. Furthermore, we see that $a \in Z$ holds, recalling that we initially assumed Z to be a set which contains a. Thus, the conjunction

$$a \in Z \wedge (a = a \vee a = b)$$

is true, which then implies $a \in \{a,b\}$ with (2.148). This shows that there exists an element in $\{a,b\}$, so that (2.146) is clearly true.

Concerning c), we let y be arbitrary and observe in light of (2.145) that $\{a,b\}$ and y satisfy

$$y \in \{a,b\} \Leftrightarrow [y \in Z \wedge (y = a \vee y = b)]. \tag{2.149}$$

Noting that $\{a,b\}$ is nonempty according to b), we prove the first part ('$\Rightarrow$') of the equivalence in (2.147) directly, assuming $y \in \{a,b\}$ to be true. This assumption implies with (2.149) in particular the disjunction $y = a \vee y = b$, which proves already the first part of the equivalence in (2.147). To prove the second part ('$\Leftarrow$'), we now assume the preceding disjunction to be true, which evidently implies $y \in Z$ irrespective of whether $y = a$ or $y = b$ holds, because Z was assumed to contain both a and b. Thus, the conjunction in (2.149) is true, which in turn implies $y \in \{a,b\}$. This proves the second part of the equivalence in (2.147), and as y was arbitrary, we therefore conclude that the set $\{a,b\}$ satisfies the universal sentence (2.147).

As a, b and Z were arbitrary, we finally conclude that the theorem is true. □

Exercise 2.14. Prove the uniqueness part of the uniquely existential sentence (2.145).

(Hint: Proceed in analogy to the corresponding proof for the intersection of a pair.)

Note 2.13. The preceding exercise should convince us sufficiently of the fact that the proof of the uniqueness part always follows exactly the same line of arguments, irrespective of the specific form of the formula $\varphi(y)$ and irrespective of the underlying set from which an element y with that definite property $\varphi(y)$ is 'picked out'. We may indeed use the proof of the uniqueness part in the proof of Theorem 2.15 as a template and simply replace the set

A and the formula '$y \in B$' by another set and another formula. Therefore, whenever we use a given set and a given definite property to establish the unique existence of a new set, we will in the following simply state the uniquely existential sentence without proving it in detail.

Definition 2.14 (Pair). For any a and b we call the set $\{a, b\}$ consisting of a and b, in the sense that

$$\forall y\,(y \in \{a, b\} \Leftrightarrow [y = a \lor y = b]),$$

the *pair* formed by a and b. We symbolize this set also by

$$\{y : y = a \lor y = b\}. \tag{2.150}$$

The following fundamental property of a pair is readily obtained from its definition.

Exercise 2.15. Verify the following sentence.

$$\forall a, b\,(a, b \in \{a, b\}). \tag{2.151}$$

(Hint: Recall the proof of Theorem 2.48b) in connection with (2.151).)

Evidently, whenever a happens to be equal to b, the corresponding pair $\{a, b\}$ can be written as $\{a, a\}$ or $\{b, b\}$, which are sets with a single element.

Notation 2.2 (Singleton). For any a we write

$$\{a\} = \{a, a\} \tag{2.152}$$

and call this pair formed by a and a the *singleton* formed by a.

Corollary 2.49. *Any a is element of the singleton formed by a, that is,*

$$\forall a\,(a \in \{a\}). \tag{2.153}$$

Proof. Letting a be arbitrary, we have $a \in \{a, a\}$ due to (2.151), so that substitution based on (2.152) yields $a \in \{a\}$. Since a is arbitrary, this is then true for all a. □

The concepts of a pair and of a singleton allow us to define two more 'natural numbers'.

Definition 2.15 (One). We call the set

$$1 = \{0\} \tag{2.154}$$

the (*number*) *one*.

Note 2.14. Due to (2.49), the set 1 can also be written in terms of the empty set, i.e.

$$1 = \{0\} = \{\emptyset\}. \tag{2.155}$$

Definition 2.16 (Two). We call the set

$$2 = \{0, 1\} \tag{2.156}$$

the (*number*) *two*.

Note 2.15. Because of (2.49 and (2.154), we can also express the set 2 solely by using $\emptyset$, that is,

$$2 = \{0, 1\} = \{\emptyset, \{\emptyset\}\}. \tag{2.157}$$

To summarize, we begin with the empty set $0 = \{\ \}$, then we include 0 in that set to form the singleton $1 = \{0\}$, and then we include 1 to the preceding set to form the pair $2 = \{0, 1\}$.

Before constructing further numbers, we establish a few facts for pairs and singletons, which we will apply in subsequent chapters.

2.5.1. Basic laws for pairs

We begin with the observation that the intersection of two sets is not only colloquially but also technically identical with the intersection of a pair.

Proposition 2.50. *The intersection of two sets A and B is identical with the intersection of the pair formed by A and B, that is,*

$$\forall A, B\,(A \cap B = \bigcap\{A, B\}). \tag{2.158}$$

Proof. We let A and B be arbitrary sets and apply the Equality Criterion for sets to prove the equation $A \cap B = \bigcap\{A, B\}$. To do this, we verify the equivalent

$$\forall y\,(y \in A \cap B \Leftrightarrow y \in \bigcap\{A, B\}). \tag{2.159}$$

Letting y be arbitrary, we now prove the first part ('$\Rightarrow$') of the equivalence directly by assuming $y \in A \cap B$ to be true. Consequently, $y \in A$ and $y \in B$ are both true by definition of the intersection of two sets. To show that this implies $y \in \bigcap\{A, B\}$, we now apply the definition of the intersection of a set system and demonstrate the truth of the equivalent universal sentence

$$\forall Y\,(Y \in \{A, B\} \Rightarrow y \in Y). \tag{2.160}$$

We take an arbitrary $Y \in \{A, B\}$, which gives $Y = A \vee Y = B$ with the definition of a pair, so that we may now prove the desired consequent

$y \in Y$ by cases. If the first part $Y = A$ of this disjunction holds, then the previously established $y \in A$ gives $y \in Y$ via substitution. Similarly, if the second part $Y = B$ of the preceding disjunction holds, then the previously obtained $y \in B$ yields $y \in Y$, too. We thus showed that $Y \in \{A, B\}$ implies $y \in Y$ in any case, and since Y is arbitrary, we may therefore conclude that the universal sentence (2.160) is true. Thus, the equivalent $y \in \bigcap\{A, B\}$ also holds, so that the proof of the first part of the equivalence in (2.159) is complete.

To prove the second part ('$\Leftarrow$'), we let y be arbitrary and assume $y \in \bigcap\{A, B\}$ to be true, so that y satisfies the universal sentence (2.160) by definition of the intersection of a set system. Next, we verify that this implies $y \in A \cap B$, or equivalently $y \in A \wedge y \in B$ (applying the definition of the intersection of two sets). Let us now recall the truth of $A \in \{A, B\}$ and $B \in \{A, B\}$ in light of (2.151), where the former implies $y \in A$ and the latter $y \in B$ with (2.160). Thus, the conjunction $y \in A \wedge y \in B$ is true, and therefore the equivalent $y \in A \cap B$ also holds, which completes the proof of the equivalence in (2.159). Since y is arbitrary, we may therefore conclude that the universal sentence (2.159), and thus the equivalent equation in (2.158), is true. Then, as A and B were also arbitrary, it follows from this that the proposed universal sentence (2.158) holds, as claimed. □

Next, we give a formal expression to the evident fact that two pairs are the same whenever their element are the same. The following exercise serves as a preparation for this task.

Exercise 2.16. Show for any a and any b that the pair formed by a and b is identical with the pair formed by b and a, that is,

$$\forall a, b\,(\{a, b\} = \{b, a\}). \tag{2.161}$$

(Hint: Use (2.147) and (1.37).)

Theorem 2.51 (Equality Criterion for pairs). *The following sentence is true.*

$$\forall a, b, a', b'\,(\{a, b\} = \{a', b'\} \Leftrightarrow [(a = a' \wedge b = b') \vee (a = b' \wedge b = a')]). \tag{2.162}$$

Proof. We begin the proof by letting a, b, a' and b' be arbitrary.

We prove the first part ('$\Rightarrow$') of the stated equivalence directly, assuming the equation $\{a, b\} = \{a', b'\}$ to be true, so that the universal sentence

$$\forall y\,(y \in \{a, b\} \Leftrightarrow y \in \{a', b'\}) \tag{2.163}$$

follows to be also true in view of the Equality Criterion for sets. Since we have

$$\begin{aligned} a &\in \{a, b\}, \\ b &\in \{a, b\}, \\ a' &\in \{a', b'\}, \\ b' &\in \{a', b'\} \end{aligned}$$

according to (2.151), it follows with the preceding universal sentence that

$$\begin{aligned} a &\in \{a', b'\}, \\ b &\in \{a', b'\}, \\ a' &\in \{a, b\}, \\ b' &\in \{a, b\} \end{aligned}$$

also hold. These four sentences in turn imply with the definition of a pair the respective disjunctions

$$\begin{aligned} a = a' &\vee a = b', \\ b = a' &\vee b = b', \\ a' = a &\vee a' = b, \\ b' = a &\vee b' = b, \end{aligned}$$

so that the conjunction

$$([a = a' \vee a = b'] \wedge [b = a' \vee b = b']) \wedge ([a' = a \vee a' = b] \wedge [b' = a \vee b' = b])$$

is true, which we may also write as

$$([a = a' \vee a = b'] \wedge [b = a' \vee b = b']) \wedge ([a = a' \vee b = a'] \wedge [a = b' \vee b = b']).$$

Because of the Commutative Law for sentences (1.37), this yields

$$([a = b' \vee a = a'] \wedge [b = a' \vee b = b']) \wedge ([b = a' \vee a = a'] \wedge [a = b' \vee b = b']).$$

Next, we apply the Associative Law for sentences (1.39) twice to rearrange the brackets, so that we obtain first

$$[a = b' \vee a = a'] \wedge ([b = a' \vee b = b'] \wedge ([b = a' \vee a = a'] \wedge [a = b' \vee b = b']))$$

and then

$$[a = b' \vee a = a'] \wedge (([b = a' \vee b = b'] \wedge [b = a' \vee a = a']) \wedge [a = b' \vee b = b']).$$

We are now in a position to apply the Distributive Law for sentences (1.45), which gives

$$[a = b' \ \vee \ a = a'] \ \wedge \ ((b = a' \ \vee \ [b = b' \ \wedge \ a = a']) \ \wedge \ [a = b' \ \vee \ b = b']).$$

Applying now first the Commutative Law for sentences (1.36), we obtain

$$[a = b' \ \vee \ a = a'] \ \wedge \ ([a = b' \ \vee \ b = b'] \ \wedge \ (b = a' \ \vee \ [b = b' \ \wedge \ a = a'])),$$

and then with the Associative Law for sentences (1.39)

$$([a = b' \ \vee \ a = a'] \ \wedge \ [a = b' \ \vee \ b = b']) \ \wedge \ (b = a' \ \vee \ [b = b' \ \wedge \ a = a']).$$

Subsequently, the Distributive Law for sentences (1.45) gives

$$(a = b' \vee [a = a' \wedge b = b']) \wedge (b = a' \vee [b = b' \wedge a = a']),$$

and another application of the Commutative Law for sentences (1.37) results in

$$([a = a' \ \wedge \ b = b'] \ \vee \ a = b') \ \wedge \ ([a = a' \ \wedge \ b = b'] \ \vee \ b = a').$$

Finally, we arrive at the disjunction in (2.162) by using the Distributive Law for sentences (1.45) once again, so that the proof of the first part of the equivalence in (2.162) is complete.

To prove the second part ('$\Leftarrow$'), we now assume the disjunction

$$(a = a' \ \wedge \ b = b') \ \vee \ (a = b' \ \wedge \ b = a')$$

to be true. On the one hand, if $a = a' \ \wedge \ b = b'$ holds, then we immediately obtain $\{a, b\} = \{a', b'\}$ via substitution. On the other hand, if $a = b' \wedge b = a'$ holds, then we obtain

$$\{a, b\} = \{b', a'\} = \{a', b'\}$$

by applying substitution and (2.161), and therefore again $\{a, b\} = \{a', b'\}$. Thus, the second part of the equivalence in (2.162) also holds.

As a, b, a' and b' are arbitrary, we therefore conclude that the theorem is true. $\square$

For later reference, we also state and prove the following rather obvious

Proposition 2.52. *For any elements a and b of a set X it is true that the pair formed by a and b is included in X, that is,*

$$\forall X, a, b\,(a, b \in X \Rightarrow \{a, b\} \subseteq X). \qquad (2.164)$$

Proof. We let X, a and b be arbitrary and assume $a, b \in X$ to be true. To prove the inclusion $\{a, b\} \subseteq X$, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall y\,(y \in \{a, b\} \Rightarrow y \in X). \tag{2.165}$$

For this purpose, we let $y \in \{a, b\}$ be arbitrary, which implies by definition of a pair the disjunction $y = a \lor y = b$, which we now use to prove the sentence $y \in X$ by cases. In case $y = a$ holds, then the assumed $a \in X$ gives the desired $y \in X$ via substitution. Similarly, if $y = b$ holds, then the initial assumption $b \in X$ yields $y \in X$, as desired. As y is arbitrary, we therefore conclude that (2.165) holds, so that $\{a, b\} \subseteq X$ follows to be true by definition of a subset. This in turn proves the implication in (2.164), and since a and b are arbitrary, we may then further conclude that the universal sentence (2.164) also holds. Finally, because X was also arbitrary, it then follows that the proposed sentence is true. □

2.5.2. Basic laws for singletons

Exercise 2.17. Show for any a, any a' and any b' that the singleton formed by a is identical with the pair formed by a' and b' iff a is identical both with a and with b', that is,

$$\forall a, a', b'\,(\{a\} = \{a', b'\} \Leftrightarrow [a = a' \land a = b']). \tag{2.166}$$

(Hint: Use (2.152), (2.162), (1.36), and (1.34)).

Exercise 2.18. Show for any a and any b that the pair formed by a and b is identical with the singleton formed by a iff a is identical with b, that is,

$$\forall a, b\,(\{a, b\} = \{a\} \Leftrightarrow a = b). \tag{2.167}$$

(Hint: Use (2.152), (2.162), (1.36), and (1.34)).

Theorem 2.53 (Equality Criterion for singletons). *The singleton formed by an a is identical with the singleton formed by an a' iff a and a' are identical, that is,*

$$\forall a, a'\,(\{a\} = \{a'\} \Leftrightarrow a = a'). \tag{2.168}$$

Proof. Letting a and a' be arbitrary, we obtain the true equivalences

$$\begin{aligned} \{a\} = \{a'\} &\Leftrightarrow \{a\} = \{a', a'\} \\ &\Leftrightarrow a = a' \land a = a' \\ &\Leftrightarrow a = a' \end{aligned}$$

by applying substitution based on the notation for singletons, then (2.166), and finally the Idempotent Law (1.33). Consequently, the equivalence in (2.168) is true, and since a and a' were arbitrary, it follows that the proposed universal sentence holds. $\square$

Proposition 2.54. *For any y and a it is true that y and a are identical iff y is an element of the singleton formed by a, that is,*

$$\forall y, a\,(y = a \Leftrightarrow y \in \{a\}). \tag{2.169}$$

Proof. We let y and a be arbitrary and observe the truth of the equivalences

$$\begin{aligned} y = a \ &\Leftrightarrow\ y = a \lor y = a \\ &\Leftrightarrow\ y \in \{a, a\} \\ &\Leftrightarrow\ y \in \{a\} \end{aligned}$$

in view of the Idempotent Law for the disjunction, the definition of a pair and the notation for a singleton. Then, the equivalence in (2.169) follows to be true, and since y and a were arbitrary, we therefore conclude that the proposed universal sentence holds. $\square$

Proposition 2.55. *It is true that the intersection of the singleton formed by any set is identical with that set, that is,*

$$\forall X\,(\bigcap\{X\} = X). \tag{2.170}$$

Proof. We let X be an arbitrary set and prove the equation by means of the Equality Criterion for sets, i.e. by verifying

$$\forall y\,(y \in \bigcap\{X\} \Leftrightarrow y \in X). \tag{2.171}$$

We take an arbitrary y and assume first $y \in \bigcap\{X\}$ to be true, which implies the truth of

$$\forall A\,(A \in \{X\} \Rightarrow y \in A). \tag{2.172}$$

with the definition of the intersection of a set system. Then, since $X \in \{X\}$ is also true according to (2.153), it follows with the preceding universal sentence that $y \in X$ holds, as desired. Thus, the first part ('$\Rightarrow$') of the equivalence in (2.171) holds. To establish the second part ('$\Leftarrow$'), we assume now $y \in X$ to be true and prove the universal sentence (2.172), which will imply the desired consequent $y \in \bigcap\{X\}$ by definition of the intersection of a set system. Letting A be arbitrary and assuming $A \in \{X\}$ to be true, we obtain the true equation $A = X$ with (2.169), so that the assumed $y \in X$ yields $y \in A$ via substitution. Thus, the implication in (2.172) is true, and because A is arbitrary, we may therefore conclude that the universal sentence (2.172) holds. Consequently, $y \in \bigcap\{X\}$ also holds, which finding completes the proof of the equivalence in (2.171). Since y is also arbitrary, we may further conclude that the universal sentence (2.171) holds, which in turn implies $\bigcap\{X\} = X$ (with the Equality Criterion for Sets). Finally, as the set X was arbitrary, we may infer from the truth of this equation the truth of the proposition. $\square$

Proposition 2.56. *A set X and the singleton formed by an a are disjoint if a is not element of X, that is,*

$$\forall a, X \, (a \notin X \Rightarrow X \cap \{a\} = \emptyset). \tag{2.173}$$

Proof. We let a and X be arbitrary and prove the implication by contradiction, assuming $a \notin X$ and $X \cap \{a\} \neq \emptyset$ to be both true. The latter implies with (2.42) that there exists an element in $X \cap \{a\}$, say $\bar{y}$. By definition of the intersection of a pair, it now follows that $\bar{y} \in X$ and $\bar{y} \in \{a\}$ are both true. The latter finding then further implies $\bar{y} = a$ with (2.169), so that the former former gives $a \in X$ via substitution. Since we assumed $a \notin X$ to be also true, we obtained a contradiction, so that the proof of the implication in (2.173) is complete. Since a and X were arbitrary, we may therefore conclude that the proposed universal sentence holds. $\square$

Exercise 2.19. Verify that the singletons formed by an y and by an a are disjoint if y and a are distinct, that is,

$$\forall y, a \, (y \neq a \Rightarrow \{y\} \cap \{a\} = \emptyset). \tag{2.174}$$

(Hint: You may proceed in analogy to the proof of Proposition 2.173.)

Proposition 2.57. *For any a and any b the intersection of the singleton formed by a and the pair formed by a and b is identical with the singleton formed by a, that is,*

$$\forall a, b \, (\{a\} \cap \{a, b\} = \{a\}). \tag{2.175}$$

Proof. We let a and b be arbitrary and apply then the Equality Criterion for sets to verify the equation in (2.175). For this purpose, we prove the universal sentence

$$\forall y \, (y \in \{a\} \cap \{a, b\} \Leftrightarrow y \in \{a\}). \tag{2.176}$$

Letting y be arbitrary, we obtain the true equivalences

$$\begin{aligned} y \in \{a\} \cap \{a, b\} \; &\Leftrightarrow \; y \in \{a\} \wedge y \in \{a, b\} \\ &\Leftrightarrow \; y = a \wedge (y = a \vee y = b) \end{aligned}$$

by applying the definition of the intersection of two sets and then (2.169) together with the definition of a pair. We may therefore evidently write the equivalence in (2.176) to be proven equivalently as

$$[y = a \land (y = a \lor y = b)] \Leftrightarrow y = a. \tag{2.177}$$

We now prove the first part ('⇒') of this equivalence directly, assuming that $y = a \land (y = a \lor y = b)$ holds. This conjunction implies in particular the desired $y = a$, which proves already the implication '⇒'. To prove the second part ('⇐'), we now assume $y = a$ to be true. Then, the disjunction $y = a \lor y = b$ is also true, so that the desired conjunction in (2.177) holds, completing the proof of the equivalence. Consequently, the equivalent equivalence in (2.176) is also true, and since y is arbitrary, we may now conclude that the universal sentence (2.176) holds. Then, the equation in (2.175) follows to be true with the Equality Criterion for sets, and as a and b were also arbitrary, we may further conclude that the proposed universal sentence (2.175) holds, as claimed. □

Proposition 2.58. *The difference of a genuine pair and the singleton formed by one of the pair's elements is the singleton formed by the other element of the pair, i.e.*

$$\forall a, b\,(a \neq b \Rightarrow \{a, b\} \setminus \{a\} = \{b\}). \tag{2.178}$$

Proof. We let a and b be distinct elements of the universe. To prove that the sets $\{a, b\} \setminus \{a\}$ and $\{b\}$ are identical, we apply the Equality Criterion for sets. For this purpose, we let y be arbitrary and then obtain the true equivalences

$$\begin{aligned}
y \in \{a, b\} \setminus \{a\} &\Leftrightarrow y \in \{a, b\} \land y \notin \{a\} \\
&\Leftrightarrow (y = a \lor y = b) \land y \neq a \\
&\Leftrightarrow (y \neq A \land y = a) \lor (y \neq a \land y = b) \\
&\Leftrightarrow y \neq A \land y = b \\
&\Leftrightarrow y \in \{b\} \land y \notin \{a\} \\
&\Leftrightarrow y \in \{b\} \setminus \{a\} \\
&\Leftrightarrow y \in \{b\}
\end{aligned}$$

using the definition of a set difference, the definition of a pair together with (2.169), the Commutative Law for sentences (1.36) together with the Distributive Law for sentences (1.44), (1.15) with the fact that $y \neq a \land y = a$ constitutes a contradiction according to (1.11), again (1.36) as well as (2.169), again the definition of a set difference, and finally (2.107) in connection with the fact that the assumption $a \neq b$ implies $\{a\} \cap \{b\} = \emptyset$ due to (2.174). As y is arbitrary, we therefore conclude that the equation in (2.178) holds. Since a and b were also arbitrary, it then follows that the proposition holds, as claimed. □

Proposition 2.59. *For any set A it is true that an y is not element of the difference of A and the singleton formed by y, that is,*

$$\forall A, y\,(y \notin A \setminus \{y\}). \tag{2.179}$$

Proof. We let A and y be arbitrary and prove $y \notin A \setminus \{y\}$ by contradiction. For this purpose, we assume $y \in A \setminus \{y\}$ to be true, which implies the conjunction $y \in A \wedge y \notin \{y\}$ by definition of a set difference. Then, this conjunction implies in particular $y \notin \{y\}$, which evidently contradicts the fact that $y \in \{y\}$ is true according to (2.153). This completes the proof by contradiction of $y \notin A \setminus \{y\}$ is true; since A and y were arbitrary, we may therefore conclude that (2.179) holds. □

Exercise 2.20. Show that every singleton has a unique element, that is,

$$\forall a\, \exists! y\,(y \in \{a\}). \tag{2.180}$$

(Hint: Apply Method 1.17, using (2.153) and (2.169).)

Theorem 2.60 (Characterization of singletons). *It is true that a set X is the singleton formed by constant a if, and only if, X is nonempty and any element of X is identical with a, that is,*

$$\forall X, a\,(X = \{a\} \Leftrightarrow [X \neq \emptyset \wedge \forall x\,(x \in X \Rightarrow x = a)]). \tag{2.181}$$

Proof. Letting X and a be arbitrary, we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $X = \{a\}$ to be true. Let us now observe in light of (2.180) that there exists a unique constant y such that $y \in \{a\}$ holds. Consequently, $[X =]\ \{a\} \neq \emptyset$ is true according to (2.42), proving the first part of the conjunction in (2.181). Next, we let x be arbitrary and assume $x \in X$ to be true. Then, substitution yields $x \in \{a\}$, and this finding implies $x = a$ with (2.169). Because x is arbitrary, we may therefore conclude that the second part of the desired conjunction also holds, completing the proof of the first part of the equivalence in (2.181). We now prove the second part ('$\Leftarrow$') by contraposition, for which purpose we assume $X \neq \{a\}$ to be true. We may write the desired consequent

$$\neg[X \neq \emptyset \wedge \forall x\,(x \in X \Rightarrow x = a)]$$

equivalently as

$$X = \emptyset \vee \exists x\,(x \in X \wedge x \neq a), \tag{2.182}$$

using De Morgan's Law for the conjunction in connection with the Double Negation Law and the Negation Law for universal implications. We now prove this disjunction by cases, based on the fact that the disjunction $X = \emptyset \vee X \neq \emptyset$ is true because of the Law of the Excluded Middle. The first case $X = \emptyset$ immediately implies the truth of the disjunction (2.182) to be proven. Let us observe in the second case $X \neq \emptyset$ that the assumed $X \neq \{a\}$ implies the truth of the existential sentence

$$\exists y\,([y \in X \,\wedge\, y \notin \{a\}] \,\vee\, [y \in \{a\} \,\wedge\, y \notin X]).$$

according to (2.23). Thus, there is a particular constant $\bar{y}$ such that

$$[\bar{y} \in X \,\wedge\, \bar{y} \notin \{a\}] \,\vee\, [\bar{y} \in \{a\} \,\wedge\, \bar{y} \notin X]$$

holds. We may now use this disjunction to prove the existential sentence in (2.182) by cases. On the one hand, if $\bar{y} \in X \,\wedge\, \bar{y} \notin \{a\}$ is true, then the second part of this conjunction yields $\bar{y} \neq a$ with (2.169). Together with the first part of the preceding conjunction, this shows that there exists indeed a constant x satisfying both $x \in X$ and $x \neq a$. On the other hand, if $\bar{y} \in \{a\} \,\wedge\, \bar{y} \notin X$ is true, then the first part of this conjunction gives $\bar{y} = a$ with (2.169), so that the second part of the conjunction implies $a \notin X$ via substitution. Since the current case assumption $X \neq \emptyset$ implies the existence of a particular element $\bar{x} \in X$, we may now infer from the two findings $\bar{x} \in X$ and $a \notin X$ the truth of $\bar{x} \neq a$ by applying (2.4). Having found the constant $\bar{x}$ satisfying both $\bar{x} \in X$ and $\bar{x} \neq a$, we have that the existential sentence in (2.182) holds again. Thus, the proof of the disjunction (2.182) is complete, and this establishes the desired consequent of the proof by contraposition. Therefore, the equivalence in (2.181) holds, and since X and a were arbitrary, we may then further conclude that the proposed universal sentence is true. $\square$

Exercise 2.21. Show that a set X is neither empty nor a singleton iff X contains two distinct elements, that is,

$$\forall X\,([X \neq \emptyset \wedge \forall a\,(X \neq \{a\})] \Leftrightarrow \exists x\,\exists y\,(x \in X \,\wedge\, y \in X \,\wedge\, x \neq y)). \quad (2.183)$$

(Hint: Concerning '$\Rightarrow$', apply Method 1.10 with (1.54), (1.81), (1.90), (1.51), (1.53), (1.35), and consider then the two cases $X = \emptyset$ and $X \neq \emptyset$ in connection with the Characterization of singletons.)

Exercise 2.22. Show that a constant y is contained in a set A iff the singleton formed by y is included in A, that is,

$$\forall A, y\,(y \in A \Leftrightarrow \{y\} \subseteq A). \quad (2.184)$$

(Hint: Use Method 1.6 and Method 1.11 in connection with (2.169), (2.9) and (2.153).)

Corollary 2.61. *For any a and any b the singletons formed by a and b are subsets of the pair formed by a and b, that is,*

$$\forall a, b\,(\{a\} \subseteq \{a,b\} \,\wedge\, \{b\} \subseteq \{a,b\}). \tag{2.185}$$

Proof. We let a and b be arbitrary and observe the truth of $a \in \{a,b\}$ and of $b \in \{a,b\}$ in light of 2.151. These findings in turn imply, respectively, $\{a\} \subseteq \{a,b\}$ and $\{b\} \subseteq \{a,b\}$ with (2.184), so that the conjunction in (2.185) holds. Since a and b were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Proposition 2.62. *Any nonempty subset A of a singleton $\{y\}$ equals that singleton, that is,*

$$\forall A, y\,([A \subseteq \{y\} \,\wedge\, A \neq \emptyset] \Rightarrow A = \{y\}). \tag{2.186}$$

Proof. We let A and y be arbitrary and prove the implication directly. For this purpose, we assume both $A \subseteq \{y\}$ and $A \neq \emptyset$ to be true. Due to the definition of the empty set in connection with (2.41), we have that $A \neq \emptyset$ implies that there exists an element of A, say $\bar{y}$. Then, $\bar{y} \in A$ implies $\bar{y} \in \{y\}$ with the assumption $A \subseteq \{y\}$ and the definition of a subset. In view of (2.169), we now see that $\bar{y} \in \{y\}$ implies $\bar{y} = y$, so that $\bar{y} \in A$ implies $y \in A$ with substitution. The latter then further implies $\{y\} \subseteq A$ with (2.184). Finally, the conjunction of this and the assumption $A \subseteq \{y\}$ implies the desired $\{y\} = A$ with the Axiom of Extension. This equation proves the implication in (2.186), and since A and y were arbitrary, we therefore conclude that the proposition holds. □

Exercise 2.23. Show that any proper subset of a singleton is empty, i.e.

$$\forall A, y\,(A \subset \{y\} \Rightarrow A = \emptyset). \tag{2.187}$$

(Hint: Use Method 1.11, (2.25), and (2.186).)

Proposition 2.63. *If a set A is a subset of a set C and if y is not an element of A, then A is a subset of the difference of C and the singleton formed by y, that is,*

$$\forall A, C, y\,([A \subseteq C \,\wedge\, y \notin A] \Rightarrow A \subseteq C \setminus \{y\}). \tag{2.188}$$

Proof. We let A, C and y be arbitrary and prove the implication directly. For this purpose, we assume that $A \subseteq C$ and $y \notin A$ are true and show that this implies the inclusion $A \subseteq C \setminus \{y\}$, which is equivalent to

$$\forall x\,(x \in A \Rightarrow x \in C \setminus \{y\}) \tag{2.189}$$

by definition of a subset. To prove this universal sentence, we let x be arbitrary and consider the two cases $A = \emptyset$ and $A \neq \emptyset$. In the first case, $x \in A$ is false by definition of the empty set, and therefore the implication is true, having a false antecedent. In the second case $A \neq \emptyset$, we prove the implication by contradiction, assuming that both $x \in A$ and $\neg x \in C \setminus \{y\}$ are true. The latter means $\neg(x \in C \wedge x \notin \{y\})$ by definition of a set difference, and therefore $x \notin C \vee x \in \{y\}$ with De Morgan's Law (1.51) and the Double Negation Law. Thus, at least one part of this disjunction is true. If $x \notin C$ holds, then this contradicts the fact that the assumption $x \in A$ implies $x \in C$ with the initial assumption $A \subseteq C$ (and the definition of a subset). If $x \in \{y\}$ holds, then also $x = y$ due to (2.169), so that $x \in A$ now implies $y \in A$, which contradicts the initial assumption $y \notin A$. This proves the universal sentence (2.189), that is, $A \subseteq C \setminus \{y\}$, and thus the implication in (2.188). Since A, C and y were arbitrary, we therefore conclude that the proposition is true. □

Exercise 2.24. Show that if a set B is included in a set A, then the difference of B and a singleton $\{y\}$ is included in the difference of A and $\{y\}$, that is,

$$\forall A, B, y\,(B \subseteq A \Rightarrow B \setminus \{y\} \subseteq A \setminus \{y\}). \tag{2.190}$$

(Hint: Use Method 1.6 alongside Definition 2.2 and Definition 2.12.)

Proposition 2.64. *It is true that, if a set B is a proper subset of a set A, then the difference of B and the singleton $\{y\}$ formed by an element y of B is a proper subset of the difference of A and the singleton $\{y\}$, that is,*

$$\forall A, B, y\,([B \subset A \wedge y \in B] \Rightarrow B \setminus \{y\} \subset A \setminus \{y\}). \tag{2.191}$$

Proof. We let A, B and y be arbitrary and prove the implication directly, assuming $B \subset A$ and $y \in B$ to be true. To show that this implies $B \setminus \{y\} \subset A \setminus \{y\}$, we prove the equivalent (applying the definition of a proper subset)

$$B \setminus \{y\} \subseteq A \setminus \{y\} \;\wedge\; B \setminus \{y\} \neq A \setminus \{y\}. \tag{2.192}$$

To prove the first part of this conjunction, we observe that the assumption $B \subset A$ implies (by definition of a proper subset) that $B \subseteq A$ and $B \neq A$ are both true; here, $B \subseteq A$ already implies the desired $B \setminus \{y\} \subseteq A \setminus \{y\}$ with (2.190). To prove the second part of the conjunction (2.192), we notice that $B \neq A$ implies with (2.23) that there is an element, say $\bar{y}$, such that

$$(\bar{y} \in B \;\wedge\; \bar{y} \notin A) \;\vee\; (\bar{y} \in A \;\wedge\; \bar{y} \notin B). \tag{2.193}$$

holds. Let us also observe that the assumption $y \in B$ implies $y \in A$ with the previously obtained $B \subseteq A$ and the definition of a subset, so that $y \in B$

and $y \in A$ are both true. We now use the true disjunction (2.193) to carry out a proof by cases of the sentence $y \neq \bar{y}$. We assume the first part $\bar{y} \in B \wedge \bar{y} \notin A$ of the disjunction to be true, which implies in particular $\bar{y} \notin A$, and carry out a proof by contradiction. To do this, we assume $y = \bar{y}$, so that $y \in A$ implies $\bar{y} \in A$. Thus, $\bar{y} \notin A$ and $\bar{y} \in A$ are both true, so that we have a contradiction according to (1.11). We now assume the second part $\bar{y} \in A \wedge \bar{y} \notin B$ of the disjunction (2.193) to be true, which implies in particular $\bar{y} \notin B$, and carry out another proof by contradiction. For this purpose, we again assume $y = \bar{y}$, so that $y \in B$ implies $\bar{y} \in B$. Thus, $\bar{y} \notin B$ and $\bar{y} \in B$ are both true, so that we have a contradictioin also in the second case, which completes the proof of $y \neq \bar{y}$. Now, this inequality evidently implies $\bar{y} \notin \{y\}$ with (2.169). Thus, the conjunction of this and (2.193) is true, which reads

$$\bar{y} \notin \{y\} \wedge [(\bar{y} \in B \wedge \bar{y} \notin A) \vee (\bar{y} \in A \wedge \bar{y} \notin B)].$$

With the Distributive Law for sentences (1.44), this yields

$$[\bar{y} \notin \{y\} \wedge \bar{y} \in B \wedge \neg \bar{y} \in A] \vee [\bar{y} \notin \{y\} \wedge \bar{y} \in A \wedge \neg \bar{y} \in B]. \tag{2.194}$$

As $\bar{y} \notin \{y\}$ is true, it follows that $\neg \bar{y} \notin \{y\}$ is a contradiction, so that $\neg \bar{y} \in A$ is equivalent to $\neg \bar{y} \in A \vee \neg \bar{y} \notin \{y\}$ and $\neg \bar{y} \in B$ equivalent to $\neg \bar{y} \in B \vee \neg \bar{y} \notin \{y\}$ because of (1.15). We may therefore rewrite (2.194) equivalently as

$$\begin{aligned}&[\bar{y} \notin \{y\} \wedge \bar{y} \in B \wedge (\neg \bar{y} \in A \vee \neg \bar{y} \notin \{y\})] \\ &\quad \vee [\bar{y} \notin \{y\} \wedge \bar{y} \in A \wedge (\neg \bar{y} \in B \vee \neg \bar{y} \notin \{y\})],\end{aligned}$$

which is also equivalent to

$$\begin{aligned}&[\bar{y} \in B \wedge \bar{y} \notin \{y\} \wedge \neg(\bar{y} \in A \wedge \bar{y} \notin \{y\})] \\ &\quad \vee [\bar{y} \in A \wedge \bar{y} \notin \{y\} \wedge \neg(\bar{y} \in B \wedge \bar{y} \notin \{y\})]\end{aligned}$$

because of the Commutative Law for sentences (1.36) and De Morgan's Law for sentences (1.51). Then, the definition of a set difference gives

$$[\bar{y} \in B \setminus \{y\} \wedge \bar{y} \notin A \setminus \{y\}] \vee [\bar{y} \in A \setminus \{y\} \wedge \bar{y} \notin B \setminus \{y\}].$$

This proves the existential sentence

$$\exists x\,([x \in B \setminus \{y\} \wedge x \notin A \setminus \{y\}] \vee [x \in A \setminus \{y\} \wedge x \notin B \setminus \{y\}]),$$

which implies the desired $B \setminus \{y\} \neq A \setminus \{y\}$ with (2.23). Thus, the proof of the conjunction (2.192) is complete, so that $B \setminus \{y\}$ is indeed a proper subset of $A \setminus \{y\}$. Since A, B and y were arbitrary, we therefore conclude that the proposed universal sentence (2.64) is true. □

2.6. Unions of Sets

To express the next number 3 as a set according to this mechanism, we would should 'add' 2 to the set $\{0, 1\}$ to form a 'triplet'. To enable such an operation is the purpose of the following axiom.

Axiom 2.4 (Axiom of union). For any set system $\mathcal{S}$ there exists a set V which contains all the elements of all the sets in $\mathcal{S}$, that is,

$$\forall \mathcal{S}\, \exists V\, \forall A\, \forall y\, ([y \in A \,\wedge\, A \in \mathcal{S}] \Rightarrow y \in V). \tag{2.195}$$

As for the pair, we will rule out for the sake of uniqueness any possible elements of V which are not in any of the sets of the given set system.

Theorem 2.65. *The following sentences are true for any set system $\mathcal{S}$ and any set V containing all the elements of all the sets in $\mathcal{S}$.*

a) There exists a unique set $\bigcup \mathcal{S}$ such that an element y is in $\bigcup \mathcal{S}$ iff y is in V and moreover in some set A in $\mathcal{S}$, that is,

$$\exists! \bigcup \mathcal{S}\, \forall y\, (y \in \bigcup \mathcal{S} \Leftrightarrow [y \in V \,\wedge\, \exists A\, (A \in \mathcal{S} \,\wedge\, y \in A)]). \tag{2.196}$$

b) The set $\bigcup \mathcal{S}$ satisfies also

$$\forall y\, (y \in \bigcup \mathcal{S} \Leftrightarrow \exists A\, (A \in \mathcal{S} \,\wedge\, y \in A)). \tag{2.197}$$

Exercise 2.25. Prove Theorem 2.65.

(Hint: Proceed in analogy to the proof of Theorem 2.28.)

Definition 2.17 (Union of a set system). For any set system $\mathcal{S}$ we call the set $\bigcup \mathcal{S}$ consisting of all the elements in all of the sets in $\mathcal{S}$, in the sense that

$$\forall y\, (y \in \bigcup \mathcal{S} \Leftrightarrow \exists A\, (A \in \mathcal{S} \,\wedge\, y \in A)),$$

the *union* of $\mathcal{S}$. This set is also symbolized by

$$\bigcup_{A \in \mathcal{S}} A \qquad \text{or} \qquad \{y : \exists A\, (A \in \mathcal{S} \,\wedge\, y \in A)\}. \tag{2.198}$$

Proposition 2.66. *The union of the singleton formed by any set is identical with that set, that is,*

$$\forall A\, (\bigcup \{A\} = A). \tag{2.199}$$

Proof. Letting $\bar{A}$ be an arbitrary set, we prove $\bigcup\{\bar{A}\} = \bar{A}$ by applying the Equality Criterion for sets, i.e. by verifying the equivalent universal sentence

$$\forall y\,(y \in \bigcup\{\bar{A}\} \Leftrightarrow y \in \bar{A}). \tag{2.200}$$

To do this, we take an arbitrary y and assume first $y \in \bigcup\{\bar{A}\}$ to be true. By definition of the union of a set system, there exists then a set, say $\bar{\bar{A}}$, such that $\bar{\bar{A}} \in \{\bar{A}\}$ and $y \in \bar{\bar{A}}$ hold. The former implies $\bar{\bar{A}} = \bar{A}$ with (2.169), so that we obtain via substitution $y \in \bar{A}$, as desired. Assuming now conversely $y \in \bar{A}$ to be true, which gives $\bar{A} \in \{\bar{A}\}$ with (2.153), we thus see that the existential sentence $\exists A\,(A \in \{\bar{A}\} \wedge y \in \{\bar{A}\})$ holds. This in turn implies the desired $y \in \bigcup\{\bar{A}\}$ with the definition of the union of a set system. Since y is arbitrary, we may therefore conclude that the universal sentence (2.200) is true, which yields then the equality $\bigcup\{\bar{A}\} = \bar{A}$. As $\bar{A}$ was arbitrary, we may now infer from the preceding equation the truth of the proposed universal sentence. □

Proposition 2.67. *For any set system $\mathcal{S}$ it is true that all of its sets are included in the union of $\mathcal{S}$, that is,*

$$\forall \mathcal{S}, A\,(A \in \mathcal{S} \Rightarrow A \subseteq \bigcup \mathcal{S}). \tag{2.201}$$

Proof. We let $\mathcal{S}$ be an arbitrary set system, A an arbitrary set in $\mathcal{S}$, and we prove $A \subseteq \bigcup \mathcal{S}$ by verifying

$$\forall y\,(y \in A \Rightarrow y \in \bigcup \mathcal{S}). \tag{2.202}$$

To do this, we let y be arbitrary and assume that $y \in A$ is true. The conjunction of this assumption and the initially assumed $A \in \mathcal{S}$ proves the existential sentence

$$\exists A\,(A \in \mathcal{S} \wedge y \in A),$$

which in turn implies $y \in \bigcup \mathcal{S}$ because of (2.197), and which thus proves the implication in (2.202). Since y is arbitrary, we therefore conclude that the universal sentence (2.202) holds, which means $A \subseteq \bigcup \mathcal{S}$ by definition of a subset. As A and $\mathcal{S}$ were also arbitrary, we finally conclude that the proposition holds, as claimed. □

Proposition 2.68. *It is true that removing the empty set from any set (system) $\mathcal{S}$ does not alter its union, that is,*

$$\forall \mathcal{S}\,(\bigcup[\mathcal{S} \setminus \{\emptyset\}] = \bigcup \mathcal{S}). \tag{2.203}$$

Proof. We take an arbitrary any set (system) $\mathcal{S}$ and apply the Equality Criterion for sets to establish the equation. For this purpose, we prove the universal sentence

$$\forall y\,(y \in \bigcup[\mathcal{S} \setminus \{\emptyset\}] \Leftrightarrow y \in \bigcup \mathcal{S}), \tag{2.204}$$

letting y be arbitrary. Regarding the first part ('$\Rightarrow$') of the equivalence, we assume $y \in \bigcup[\mathcal{S} \setminus \{\emptyset\}]$, so that there exists by definition of the union of a set system a set, say $\bar{A}$, satisfying $\bar{A} \in \mathcal{S} \setminus \{\emptyset\}$ and $y \in \bar{A}$. Because of the definition of a set difference, $\bar{A} \in \mathcal{S}$ is then true in particular. In conjunction with $y \in \bar{A}$, this implies $y \in \bigcup \mathcal{S}$ with the definition of the union of a set system, as desired.

Regarding the second part ('$\Leftarrow$') of the equivalence, we assume now $y \in \bigcup \mathcal{S}$, so that there evidently exists a particular set $\bar{B} \in \mathcal{S}$ with $y \in \bar{B}$. The latter clearly shows that $\bar{B}$ is nonempty, so that $\bar{B} \notin \{\emptyset\}$ follows to be true with (2.169). In conjunction with $\bar{B} \in \mathcal{S}$, this negation implies evidently $\bar{B} \in \mathcal{S} \setminus \{\emptyset\}$, which further implies – together with $y \in \bar{B}$ – the desired consequent $y \in \bigcup[\mathcal{S} \setminus \{\emptyset\}]$.

Having thus completed the proof of the equivalence, we may now infer from this the truth of (2.204), since y was arbitrary. Consequently, the equation in (2.203) holds as well, in which $\mathcal{S}$ is arbitrary, so that the proposed universal sentence follows to be true. □

Exercise 2.26. Prove that

a) the union of the empty set system $\emptyset$ is itself empty, that is,

$$\bigcup \emptyset = \emptyset. \tag{2.205}$$

b) the union of the singleton formed by the empty set is empty, that is,

$$\bigcup \{\emptyset\} = \emptyset. \tag{2.206}$$

(Hint: Apply (2.169).)

c) the non-emptiness of the union of a set system implies the non-emptiness of the set system, that is,

$$\forall \mathcal{S}\,(\bigcup \mathcal{S} \neq \emptyset \Rightarrow \mathcal{S} \neq \emptyset). \tag{2.207}$$

Definition 2.18 (Partition). We say for any set X that a system $\mathcal{S}$ of subsets of X is a *partition* of X iff $\mathcal{S}$ is a system of pairwise disjoint sets whose union is identical with X, i.e. iff

$$\forall A, B\,([A, B \in \mathcal{S} \,\wedge\, A \neq B] \Rightarrow A \cap B = \emptyset) \,\wedge\, \bigcup \mathcal{S} = X. \tag{2.208}$$

Definition 2.19 (Union of two sets, union of a pair). For any sets A and B we call the set

$$A \cup B = \bigcup \{A, B\} \tag{2.209}$$

the *union* of A and B.

Proposition 2.69. *The union of two sets A and B satisfies*

$$\forall y \, (y \in A \cup B \Leftrightarrow y \in A \,\vee\, y \in B). \tag{2.210}$$

Proof. Letting A and B be arbitrary sets, we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in A \cup B$ to be true. This in turn implies $y \in \bigcup\{A, B\}$ with (2.209), and then moreover with (2.197) that there exists a set, say $\bar{Y}$, such that $\bar{Y} \in \{A, B\}$ and $y \in \bar{Y}$ hold. Here, $\bar{Y} \in \{A, B\}$ implies the true disjunction $\bar{Y} = A \,\vee\, \bar{Y} = B$ with (2.147), which we may now use to prove the desired disjunction $y \in A \,\vee\, y \in B$ by cases. On the one hand, if $\bar{Y} = A$ holds, then $y \in \bar{Y}$ gives $y \in A$, and the disjunction $y \in A \,\vee\, y \in B$ is then also true. On the other hand, if $\bar{Y} = B$ is true, then $y \in \bar{Y}$ yields $y \in B$, and the disjunction $y \in A \vee y \in B$ holds again. Thus, the proof of the first part of the equivalence in (2.210) is complete.

Next, we prove the second part ('$\Leftarrow$') directly, assuming that the disjunction $y \in A \,\vee\, y \in B$ is true, which we use to prove the existential sentence

$$\exists Y \, (Y \in \{A, B\} \,\wedge\, y \in Y) \tag{2.211}$$

by cases. Let us first observe that $A, B \in \{A, B\}$ holds according to (2.151). Now, if the first part $y \in A$ of the preceding disjunction is true, then this implies together with $A \in \{A, B\}$ the truth of the existential sentence (2.211). Similarly, the second case $y \in B$ yields with $B \in \{A, B\}$ again (2.211), completing the proof by cases. Then, $y \in \bigcup\{A, B\}$ follows to be true with (2.197), and we therefore obtain with (2.209) $y \in A \cup B$, as desired, completing the proof of the second part of the equivalence in (2.210) and thus the proof of that equivalence. As y is arbitrary, we may therefore conclude that the universal sentence (2.210) is true, and since A and B were also arbitrary, it then follows that the proposition holds, as claimed. □

Notation 2.3. We symbolize the union $A \cup B$ of two sets A and B also by

$$\{y : y \in A \,\vee\, y \in B\}$$

Exercise 2.27. Show that the union of any set and any singleton is nonempty, that is,

$$\forall X, a \, (X \cup \{a\} \neq \emptyset). \tag{2.212}$$

(Hint: Use (2.153), (2.210) and (2.42).)

The concept of union also allows us to define some further *numbers*.

Definition 2.20 (Three). We call the set

$$3 = 2 \cup \{2\} \tag{2.213}$$

the (*number*) *three*.

2.6.1. Basic laws

Theorem 2.70 (Commutative Law for the union of two sets). *The union of two sets A and B is identical with the union of B and A, that is,*

$$\forall A, B\, (A \cup B = B \cup A). \tag{2.214}$$

Exercise 2.28. Prove the Commutative Law for the union of two sets.

(Hint: Proceed in analogy to the proof of the Commutative Law for the intersection of two sets.)

Theorem 2.71 (Idempotent Law for the union of two sets). *The pairwise union is idempotent in the sense that*

$$\forall A\, (A \cup A = A). \tag{2.215}$$

Exercise 2.29. Prove the Idempotent Law for the union of two sets.

(Hint: Proceed in analogy to the proof of the Idempotent Law for the intersection of two sets.)

Proposition 2.72. *The union of any set and the empty set as well as the union of the empty set and any set is the set itself, that is,*

$$\forall A\, (A \cup \emptyset = A \,\wedge\, \emptyset \cup A = A). \tag{2.216}$$

Proof. We let A be arbitrary and prove the first part of the stated conjunction by verifying

$$\forall y\, (y \in A \cup \emptyset \Leftrightarrow y \in A). \tag{2.217}$$

For this purpose, we let y be arbitrary and observe the truth of the equivalences

$$\begin{aligned} y \in A \cup \emptyset \;&\Leftrightarrow\; y \in A \,\vee\, y \in \emptyset \\ &\Leftrightarrow\; y \in A, \end{aligned}$$

using (2.210) and then (1.15) in connection with the fact that $y \in \emptyset$ is a contradiction by definition of the empty set. Thus, the equivalence $y \in$

$A \cup \emptyset \Leftrightarrow y \in A$ follows to be true, and since y is arbitrary, we may therefore conclude that (2.217) holds. This universal sentence in turn implies the desired equation $A \cup \emptyset = A$ with the Equality Criterion for sets.

Regarding the second part of the conjunction in (2.216), we notice that the equation

$$\emptyset \cup A = A \cup \emptyset \;(= A)$$

holds due to the Commutative Law for the union of two sets, which yields $\emptyset \cap A = A$. As the set A was arbitrary, we may now conclude that the proposed sentence (2.216) holds. □

Corollary 2.73. *The union of the empty set and the empty set is also empty, that is,*

$$\emptyset \cup \emptyset = \emptyset. \tag{2.218}$$

The Associative Law for sentences regarding the disjunction translates naturally to the

Theorem 2.74 (Associative Law for the union of two sets). *The union of two sets is associative in the sense that*

$$\forall A, B, C\, (A \cup [B \cup C] = [A \cup B] \cup C). \tag{2.219}$$

Exercise 2.30. Prove the Associative Law for the union of two sets.

(Hint: Proceed similarly as in the proof of the Associative Law for the intersection of two sets.)

Theorem 2.75 (Distributive Law for the union & the intersection of two sets). *The following laws are true.*

a) The union of two sets is distributive over the intersection of two sets in the sense that

$$\forall A, B, C\, (A \cup [B \cap C] = [A \cup B] \cap [A \cup C]). \tag{2.220}$$

b) The intersection of two sets is distributive over the union of two sets in the sense that

$$\forall A, B, C\, (A \cap [B \cup C] = [A \cap B] \cup [A \cap C]). \tag{2.221}$$

Proof. Concerning a), we let A, B and C be arbitrary sets and verify first the truth of

$$\forall y\, (y \in A \cup [B \cap C] \Leftrightarrow y \in [A \cup B] \cap [A \cup C]). \tag{2.222}$$

Letting y be arbitrary, we obtain the true equivalences

$$\begin{aligned}
y \in A \cup [B \cap C] &\Leftrightarrow (y \in A \lor y \in B \cap C) \\
&\Leftrightarrow (y \in A \lor [y \in B \land y \in C]) \\
&\Leftrightarrow ([y \in A \lor y \in B] \land [y \in A \lor y \in C]) \\
&\Leftrightarrow (y \in A \cup B \land y \in A \cup C) \\
&\Leftrightarrow (y \in [A \cup B] \cap [A \cup C])
\end{aligned}$$

by applying (2.210), (2.57), (1.45), again (2.210), and finally again (2.57). Thus, the equivalence in (2.222) holds, and since y is arbitrary, we may therefore conclude that (2.222) is true. It then follows from this with the Equality Criterion for sets that the equation in (2.220) also holds. As A, B and C were arbitrary, we may finally conclude that the Distributive Law a) is true. □

Exercise 2.31. Verify the Distributive Law (2.221).

Proposition 2.76. *For disjoint sets B and C we may either first 'subtract' B from a set A and then form the union with C, or equivalently form first the union of A and C and then 'subtract' B, that is,*

$$\forall A, B, C\,(B \cap C = \emptyset \Rightarrow [A \setminus B] \cup C = [A \cup C] \setminus B). \tag{2.223}$$

Proof. We let A, B and C be arbitrary sets and assume B and C to be disjoint, which assumption implies $C \setminus B = C$ with (2.107). Then, to prove the equation in (2.223), we apply the Equality Criterion for sets and verify accordingly the equivalent universal sentence

$$\forall y\,(y \in [A \setminus B] \cup C \Leftrightarrow y \in [A \cup C] \setminus B). \tag{2.224}$$

Letting y be arbitrary, we then obtain the true equivalences

$$\begin{aligned}
y \in (A \setminus B) \cup C &\Leftrightarrow y \in (A \setminus B) \cup (C \setminus B) \\
&\Leftrightarrow y \in A \setminus B \lor y \in C \setminus B \\
&\Leftrightarrow (y \in A \land y \notin B) \lor (y \in C \land y \notin B) \\
&\Leftrightarrow (y \notin B \land y \in A) \lor (y \notin B \land y \in C) \\
&\Leftrightarrow y \notin B \land (y \in A \lor y \in C) \\
&\Leftrightarrow y \in A \cup C \land y \notin B \\
&\Leftrightarrow y \in (A \cup C) \setminus B
\end{aligned}$$

using the previously established equation $C \setminus B = C$, the definition of the union of a pair, the definition of a set difference, the Commutative Law for sentences (1.36), the Distributive Law for sentences (1.44), then again the Commutative Law for sentences (1.36), the definition of the union of a pair, and the definition of a set difference. As y is arbitrary, it therefore follows that the universal sentence (2.224) holds, so that the sets $[A \setminus B] \cup C$ and $[A \cup C] \setminus B$ are identical. Since A, B and C were also arbitrary, we then conclude that the proposition (2.223) is true. □

Exercise 2.32. Show that 'removing' first a set B from a set A and then a set C from that set difference yields the same set as removing the union of B and C from A, that is,

$$\forall A, B, C\, (A \setminus [B \cup C] = [A \setminus B] \setminus C). \tag{2.225}$$

Proposition 2.77. *The union of two singletons is a pair, that is,*

$$\forall a, b\, (\{a\} \cup \{b\} = \{a, b\}). \tag{2.226}$$

Proof. We let a and b be arbitrary and establish first

$$\forall y\, (y \in \{a\} \cup \{b\} \Leftrightarrow y \in \{a, b\}), \tag{2.227}$$

letting y be arbitrary and observing the truth of

$$\begin{aligned} y \in \{a\} \cup \{b\} &\Leftrightarrow y \in \{a\} \lor y \in \{b\} \\ &\Leftrightarrow y = a \lor y = b \\ &\Leftrightarrow y \in \{a, b\} \end{aligned}$$

in light of (2.210), (2.169), and (2.147). Since y is arbitrary, we may therefore conclude that (2.227) holds, and as a and b were also arbitrary, the proposition follows to be true. □

Note 2.16. Recalling the definition of the number $2 = \{0, 1\}$ we also have according to (2.226)

$$2 = \{0\} \cup \{1\}. \tag{2.228}$$

Definition 2.21 (Triple). For any a, b and c we call the union of the pair formed by a, b and the singleton formed by c the *triple* formed by a, b and c, symbolically

$$\{a, b, c\} = \{a, b\} \cup \{c\}. \tag{2.229}$$

Exercise 2.33. Show for any a, b and c that an element y is in the triple formed by a, b and c iff y is identical with a, or with b, or with c, that is,

$$\forall a, b, c, y\, (y \in \{a, b, c\} \Leftrightarrow [y = a \lor y = b \lor y = c]). \tag{2.230}$$

(Hint: Apply (2.229), (2.210), (2.147), and (2.169).)

Exercise 2.34. Verify for any a that the triple formed by a, a and a is identical with the singleton formed by a, that is,

$$\forall a\,(\{a,a,a\} = \{a\}). \tag{2.231}$$

(Hint: Apply Exercise 2.33, Theorem 1.9, and Proposition 2.54.)

Exercise 2.35. Show for any a, any b and any c that the triple formed by a, b and c is identical with the triple formed by b, c and a, that is,

$$\forall a,b,c\,(\{a,b,c\} = \{b,c,a\}). \tag{2.232}$$

(Hint: Use (2.230) and (1.37).)

Corollary 2.78. *For any a, any b and any c it is true that a, b and c are elements of the triple formed by these constants, that is,*

$$\forall a,b,c\,(a,b,c \in \{a,b,c\}). \tag{2.233}$$

Proof. Letting a, b and c be arbitrary and $\{a,b,c\}$ the triple formed by a, b and c, we observe the truth of the equations $a = a$, $b = b$ and $c = c$. Then, the three disjunctions

$$\begin{aligned} &a = a \,\vee\, a = b \,\vee\, a = c \\ &b = a \,\vee\, b = b \,\vee\, b = c \\ &c = a \,\vee\, c = b \,\vee\, c = c \end{aligned}$$

are also true, which in turn imply $a \in \{a,b,c\}$, $b \in \{a,b,c\}$ and $c \in \{a,b,c\}$, respectively, with (2.230). Since a, b and c were arbitrary, we may therefore conclude that (2.233) holds, as claimed. □

Exercise 2.36. Show for any elements a, b and c of a set X that the triple formed by a, b and c is included in X, that is,

$$\forall a,b,c\,(a,b,c \in X \Rightarrow \{a,b,c\} \subseteq X). \tag{2.234}$$

(Hint: Proceed in analogy to the proof of Proposition 2.52.)

Note 2.17. Recalling the definition of the number $3 = 2 \cup \{2\}$, where $2 = \{0,1\}$, we obtain with the definition of a triple

$$3 = \{0,1,2\}. \tag{2.235}$$

Thus, 0 is empty, 1 is a singleton, 2 a pair and 3 a triple. Using (2.49), (2.155) and (2.157), we may also write

$$3 = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}. \tag{2.236}$$

Note 2.18. Because of the Commutative Law for the union of two sets, the union of a singleton $\{a\}$ and a pair $\{b, c\}$ also yields a triple.

Proposition 2.79. *For any a, b and c it is true that both the pair formed by a, b and the singleton formed by c are subsets of the triple formed by a, b, c, that is,*

$$\forall a, b, c\,(\{a, b\} \subseteq \{a, b, c\} \,\wedge\, \{c\} \subseteq \{a, b, c\}). \tag{2.237}$$

Proof. We let a, b and c be arbitrary, and we prove the first stated inclusion by verifying the equivalent (applying the definition of a subset)

$$\forall y\,(y \in \{a, b\} \Rightarrow y \in \{a, b, c\}). \tag{2.238}$$

For this purpose, we let y be arbitrary and assume $y \in \{a, b\}$ to be true. Then, the disjunction $y \in \{a, b\} \vee y \in \{c\}$ is also true, which in turn implies $y \in \{a, b\} \cup \{c\}$ with (2.210), and therefore $y \in \{a, b, c\}$ by definition of a triple. As y is arbitrary, we may therefore conclude that the universal sentence (2.238) is true, so that $\{a, b\} \subseteq \{a, b, c\}$ follows to be true by definition of a subset. Thus, the proof of the first part of the conjunction in (2.237) is complete.

To prove the second part $\{c\} \subseteq \{a, b, c\}$, we verify the equivalent

$$\forall y\,(y \in \{c\} \Rightarrow y \in \{a, b, c\}). \tag{2.239}$$

To do this, we let y be arbitrary and assume $y \in \{c\}$, so that the disjunction $y \in \{a, b\} \vee y \in \{c\}$ is again true. Using the same arguments as before, we obtain the desired $y \in \{a, b, c\}$, and since y is arbitrary, it follows that (2.239) holds. Consequently, $\{c\} \subseteq \{a, b, c\}$ is true (by definition of a subset), completing the proof of the stated conjunction. Because a, b and c were arbitrary, we may finally conclude that the proposed universal sentence is true. □

We now see that a pair may be viewed as a special case of a triple.

Proposition 2.80. *For any a and any b the union of the singleton formed by a and the pair formed by a and b is identical with the pair formed by a and b, that is,*

$$\forall a, b\,(\{a\} \cup \{a, b\} = \{a, b\}). \tag{2.240}$$

Proof. We let a and b be arbitrary and apply then the Equality Criterion for sets to verify the equation in (2.240). For this purpose, we prove the universal sentence

$$\forall y\,(y \in \{a\} \cup \{a, b\} \Leftrightarrow y \in \{a, b\}). \tag{2.241}$$

Letting y be arbitrary, we obtain the true equivalences

$$\begin{aligned} y \in \{a\} \cup \{a,b\} &\Leftrightarrow y \in \{a\} \lor y \in \{a,b\} \\ &\Leftrightarrow y = a \lor (y = a \lor y = b) \\ &\Leftrightarrow (y = a \lor y = a) \lor y = b \\ &\Leftrightarrow y = a \lor y = b \\ &\Leftrightarrow y \in \{a\} \lor y \in \{b\} \\ &\Leftrightarrow y \in \{a\} \cup \{b\} \\ &\Leftrightarrow y \in \{a,b\} \end{aligned}$$

by applying the definition of the union of two sets, then (2.169) together with the definition of a pair, the Associative Law for the disjunction, the Idempotent Law for the disjunction, again (2.169), again the definition of the union of two sets, and finally (2.226). As y is arbitrary, we may now conclude that the universal sentence (2.241) holds, and the equation in (2.240) follows then to be true with the Equality Criterion for sets. Since a and b were arbitrary, too, we may finally conclude that the proposed universal sentence (2.240) is true. □

Definition 2.22 (Quadruple). For any a, b, c and d we call the union of the triple formed by a, b, c and the singleton formed by d the *quadruple* formed by a, b, c and d, symbolically

$$\{a,b,c,d\} = \{a,b,c\} \cup \{d\}. \tag{2.242}$$

Exercise 2.37. Verify for any a, b, c, d that an element y is in the triple formed by a, b, c and d iff y is identical with a, or with b, or with c, or with d, that is,

$$\forall a,b,c,d,y\,(y \in \{a,b,c,d\} \Leftrightarrow [(y = a \lor y = b \lor y = c) \lor y = d]). \tag{2.243}$$

(Hint: Proceed in analogy to Exercise 2.33.)

Exercise 2.38. Show for any a, b, c, d that a, b, c and d are elements of the quadruple formed by these constants, that is,

$$\forall a,b,c,d\,(a,b,c,d \in \{a,b,c,d\}). \tag{2.244}$$

(Hint: Apply a proof similarly to the one for Corollary 2.78.)

Exercise 2.39. Define the number 4 in analogy to the number 3 and express then 4 as a quadruple in terms of the empty set.

(Hint: Use (2.235), (2.236), and (2.242).)

In the same manner we could systematically define 5 as $4 \cup \{4\}$ and so on. However, as there would clearly always be one further number to be defined (6, then 7, then 8, etc.), we could not define in this way a set consisting of these numbers in their entirety without using unlimited space and time. To achieve this, we will have to introduce another set-theoretical axiom, which we postpone until Section 2.7.

2.6.2. Basic relationships of unions with subsets

Exercise 2.40. Show that the union of two sets includes both of the sets, that is,

$$\forall A, B\,(A \subseteq A \cup B \,\wedge\, B \subseteq A \cup B). \tag{2.245}$$

(Hint: Apply (2.151), (2.201), and (2.209).)

Corollary 2.81. *The intersection of any two sets is included in the union of these sets, that is,*

$$\forall A, B\,(A \cap B \,\subseteq\, A \cup B). \tag{2.246}$$

Proof. Letting A and B be arbitrary, we obtain on the one hand $A \cap B \subseteq A$ with (2.74), and on the other hand $A \subseteq A \cup B$ with (2.245). The conjunction of these two inclusions then implies the desired $A \cap B \subseteq A \cup B$ with (2.13), and since A and B were arbitrary, we therefore conclude that the proposed universal sentence (2.246) is true. □

Proposition 2.82. *The union of a set with a subset yields the former set, that is,*

$$\forall A, B\,(A \subseteq B \Rightarrow A \cup B = B). \tag{2.247}$$

Proof. We let A and B be arbitrary sets, and we prove the implication directly, assuming A to be a subset of B, so that

$$\forall y\,(y \in A \Rightarrow y \in B) \tag{2.248}$$

holds. Next, we prove the equation $A \cup B = B$ by applying the Equality Criterion for sets, i.e. by verifying

$$\forall y\,(y \in A \cup B \Leftrightarrow y \in B). \tag{2.249}$$

To do this, we let y be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in A \cup B$ to hold. This means by definition of the union of two sets that the disjunction $y \in A \,\vee\, y \in B$ is true. Let us now carry out a proof by cases of the sentence $y \in B$ based on that disjunction. On the one hand, if $y \in A$ holds, then the desired consequent

$y \in B$ follows to be true with (2.248). On the other hand, if the second part $y \in B$ of the preceding disjunction holds, then we already arrived at the desired consequent, and the proof of the first part of the equivalence in (2.249) is complete.

To prove the second part ('$\Leftarrow$'), we now assume that $y \in B$ is true. Then, the disjunction $y \in A \vee y \in B$ is also true (irrespective of the truth value of $y \in A$), so that $y \in A \cup B$ holds by definition of the union of two sets. This completes the proof of the equivalence in (2.249), and since y is arbitrary, we may therefore conclude that (2.249) holds. This universal sentence then further implies $A \cup B = B$ with the Equality Criterion for sets, so that the proof of the implication in (2.247) is also complete. As A and B were arbitrary, we finally conclude that the proposition holds. □

Since any set is a subset of itself according to (2.10), we immediately obtain the following result with the preceding proposition.

Corollary 2.83. *Any set is identical to the union of the set with itself, i.e.*

$$\forall A\,(A \cup A = A). \tag{2.250}$$

Proposition 2.84. *The following sentences are true.*

a) If a set A is a subset of a set B, then the union of A with a set C is included in the union of B with C, that is,

$$\forall A, B, C\,(A \subseteq B \Rightarrow A \cup C \subseteq B \cup C). \tag{2.251}$$

b) Two sets A and B are subsets of a set C iff the union of A and B is a subset of C, that is,

$$\forall A, B, C\,([A \subseteq C \,\wedge\, B \subseteq C] \Leftrightarrow A \cup B \subseteq C). \tag{2.252}$$

Proof. Concerning a), we let A, B, C be arbitrary and prove the implication directly, assuming that $A \subseteq B$, or equivalently (using the definition of a subset) that

$$\forall y(y \in A \Rightarrow y \in B) \tag{2.253}$$

holds. To prove $A \cup C \subseteq B \cup C$, we demonstrate the truth of the equivalent

$$\forall y\,(y \in A \cup C \Rightarrow y \in B \cup C). \tag{2.254}$$

For this purpose, we let y be arbitrary and assume $y \in A \cup C$, which means $y \in A \vee y \in C$ by definition of the union of a pair. We use this true disjunction to prove the sentence $y \in B \cup C$ by cases. In the first case that $y \in A$ holds, it follows with (2.253) that $y \in B$ is true, which further implies the truth of the disjunction $y \in B \lor y \in C$ (no matter if $y \in C$ is true or false), and therefore the truth of $y \in B \cup C$ (using again the definition of the union of a pair). In the second case that $y \in C$ is true, the disjunction $y \in B \lor y \in C$ is evidently true as well (no matter if $y \in B$ is true or false), which yields again $y \in B \cup C$. We thus showed that $y \in A \cup C$ implies $y \in B \cup C$, and since y is arbitrary, we may therefore conclude that (2.254) is true. This proves $A \cup C \subseteq B \cup C$ and thus the implication in (2.251). As A, B and C were arbitrary, we finally conclude that a) holds.

Concerning b), we let A, B, C again be arbitrary, so that we obtain the equivalences

$$\begin{aligned} A \subseteq C \land B \subseteq C &\Leftrightarrow \forall y\,(y \in A \Rightarrow y \in C) \land \forall y\,(y \in B \Rightarrow y \in C) \\ &\Leftrightarrow \forall y\,([y \in A \Rightarrow y \in C] \land [y \in B \Rightarrow y \in C]) \\ &\Leftrightarrow \forall y\,([y \in A \lor y \in B] \Rightarrow y \in C) \\ &\Leftrightarrow \forall y\,([y \in A \cup B] \Rightarrow y \in C) \\ &\Leftrightarrow A \cup B \subseteq C \end{aligned}$$

using the definition of a subset, the Distributive Law for quantification (1.74), the Distributive Law for sentences (1.50), the definition of the union of a pair, and finally again the definition of a subset. Since A, B and C are arbitrary, we therefore conclude that b) is also true. □

Proposition 2.85. *If a set B is not included in a set A, then A is a proper subset of the union of A and B, that is,*

$$\forall A, B\,(\neg B \subseteq A \Rightarrow A \subset A \cup B). \tag{2.255}$$

Proof. We let A and B be arbitrary sets and prove the stated implication directly, assuming $\neg B \subseteq A$ to be true. According to Note 2.12, this assumption implies that there exists an element in the set difference $B \setminus A$, say $\bar{y}$. It then follows with with the definition of a subset that $\bar{y} \in B$ and $\bar{y} \notin A$ are true. Here, $\bar{y} \in B$ further implies the truth of the disjunction $\bar{y} \in A \lor \bar{y} \in B$ (even though $\bar{y} \in A$ is false), so that $\bar{y} \in A \cup B$ holds by definition of the union of two sets. Thus, the conjunction of $\bar{y} \in A \cup B$ and $\bar{y} \notin A$ is true, and then the disjunction

$$(\bar{y} \in A \land \bar{y} \notin A \cup B) \lor (\bar{y} \in A \cup B \land \bar{y} \notin A)$$

also holds, which proves the existential sentence

$$\exists y\,([y \in A \land y \notin A \cup B] \lor [y \in A \cup B \land y \notin A]).$$

Therefore, we obtain with (2.23) the inequality $A \neq A \cup B$. Let us now observe that $A \subseteq A \cup B$ is also true in view of (2.40). Then, the conjunction of $A \subseteq A \cup B$ and $A \neq A \cup B$ yields $A \subset A \cup B$ with the definition of a proper subset, which proves the implication in (2.255). Since A and B are arbitrary, we therefore conclude that the proposition is true. □

Corollary 2.86. *If a set B is not included in a set A, then A is a proper subset of the union of A and B, that is,*

$$\forall A, B\,([B \neq \emptyset \,\wedge\, B \cap A = \emptyset] \Rightarrow A \subset A \cup B). \tag{2.256}$$

Proof. Letting A and B be arbitrary sets such that $B \neq \emptyset$ and $B \cap A = \emptyset$ hold, we obtain the negation $\neg B \subseteq A$ with (2.86), which then implies the desired $A \subset A \cup B$ with (2.255). Since A and B are arbitrary, we therefore conclude that the corollary holds, as claimed. □

Let us now inspect some relationships of the union with complements.

Proposition 2.87. *The union of a subset A of a set X and the complement of A with respect to X is identical with X, that is,*

$$\forall X, A\,(A \subseteq X \Rightarrow A \cup A^c = X). \tag{2.257}$$

Proof. We let X and A be arbitrary sets, and we prove the implication directly, assuming $A \subseteq X$, so that $A \cup X = X$ follows to be true with (2.247). Next, we verify the equation $A \cup A^c = X$ by proving

$$\forall y\,(y \in A \cup A^c \Leftrightarrow y \in X). \tag{2.258}$$

We let y be arbitrary and obtain the true equivalences

$$\begin{aligned} y \in A \cup A^c &\Leftrightarrow y \in A \,\vee\, y \in A^c \\ &\Leftrightarrow y \in A \,\vee\, (y \in X \setminus A) \\ &\Leftrightarrow y \in A \,\vee\, (y \in X \,\wedge\, y \notin A) \\ &\Leftrightarrow (y \in A \,\vee\, y \in X) \,\wedge\, (y \in A \,\vee\, y \notin A) \\ &\Leftrightarrow y \in A \,\vee\, y \in X \\ &\Leftrightarrow y \in A \cup X \\ &\Leftrightarrow y \in X, \end{aligned}$$

using the definition of the union of two sets, the notation for a complement, the definition of a set difference, the Distributive Law for sentences (1.45), then (1.13) in connection with the fact that the disjunction $y \in A \,\vee\, y \notin A$ is a tautology according to (1.10), again the definition of the union of two sets, and finally the previously established equation $A \cup X = X$. These equivalences evidently yield the equivalence in (2.258), and since y is arbitrary, we therefore conclude that the (2.258) holds. This universal sentence in turn implies the desired equation $A \cup A^c = X$ with the Equality Criterion for sets, so that the proof of the implication in (2.257) is complete. As A was an arbitrary set, we may finally conclude that the proposed sentence is true. □

Theorem 2.88 (De Morgan's Laws for the intersection & the union two sets). *The following sentences are true (where the complement is formed with respect to X).*

a) **De Morgan's Law for the intersection of two sets:**

$$\forall X, A, B\,(A, B \subseteq X \Rightarrow [A \cap B]^c = A^c \cup B^c). \tag{2.259}$$

b) **De Morgan's Law for the union of two sets:**

$$\forall X, A, B\,(A, B \subseteq X \Rightarrow (A \cup B)^c = A^c \cap B^c). \tag{2.260}$$

Proof. Concerning a), we let X be an arbitrary set and A and B arbitrary subsets of X. Next, we verify

$$\forall y\,(y \in [A \cap B]^c \Leftrightarrow y \in A^c \cup B^c), \tag{2.261}$$

letting y be arbitrary. Let us now observe the truth of the equivalences

$$\begin{aligned} y \in [A \cap B]^c &\Leftrightarrow y \in X \setminus [A \cap C] \\ &\Leftrightarrow y \in X \wedge \neg y \in A \cap C \\ &\Leftrightarrow y \in X \wedge \neg(y \in A \wedge y \in C) \\ &\Leftrightarrow y \in X \wedge (y \notin A \vee y \notin C) \\ &\Leftrightarrow (y \in X \wedge y \notin A) \vee (y \in X \wedge y \notin C) \\ &\Leftrightarrow y \in X \setminus A \vee y \in X \setminus C \\ &\Leftrightarrow y \in A^c \cup B^c \end{aligned}$$

in light of the Notation for complements, the definition of a set difference, the definition of the intersection of two sets, De Morgan's Law for sentences (1.51), the Distributive Law for sentences (1.44), the definition of a set difference, and the notation for complements. As y is arbitrary, we may therefore conclude that the universal sentence (2.261) holds, which then yields the equation in (2.259) with the Equality Criterion for sets. Since A, B and C were arbitrary, we may further conclude that a) holds. □

Exercise 2.41. Prove De Morgan's Law (2.260).

(Hint: Proceed similarly as in the proof of (2.259) and apply (1.33), (1.39) as well as (1.36) instead of the Distributive Law for sentences (1.44).)

The union of two disjoint sets has two useful direct relationships with the set difference.

Proposition 2.89. *If C is the union of two disjoint sets A and B, then A is obtained by 'subtracting' B from the union C, that is,*

$$\forall A, B, C\,([A \cup B = C \,\wedge\, A \cap B = \emptyset] \Rightarrow A = C \setminus B). \tag{2.262}$$

Proof. We let A, B and Cbe arbitrary such that $A \cup B = C$ and $A \cap B = \emptyset$ hold. Here, the latter equation implies $A \setminus B = A$ with (2.107). Next, we establish for an arbitrary y the equivalences

$$\begin{aligned} y \in C \setminus B \;&\Leftrightarrow\; (y \in C \,\wedge\, y \notin B) \\ &\Leftrightarrow\; (y \in A \cup B \,\wedge\, y \notin B) \\ &\Leftrightarrow\; ([y \in A \,\vee\, y \in B] \,\wedge\, y \notin B) \\ &\Leftrightarrow\; (y \notin B \,\wedge\, [y \in A \,\vee\, y \in B]) \\ &\Leftrightarrow\; ([y \notin B \,\wedge\, y \in A] \,\vee\, [y \notin B \,\wedge\, y \in B]) \\ &\Leftrightarrow\; ([y \in A \,\wedge\, y \notin B] \,\vee\, [y \in B \,\wedge\, y \notin B]) \\ &\Leftrightarrow\; ([y \in A \setminus B] \,\vee\, [y \in B \setminus B]) \\ &\Leftrightarrow\; (y \in A \setminus B \,\vee\, y \in \emptyset) \\ &\Leftrightarrow\; (y \in A \,\vee\, y \in \emptyset) \\ &\Leftrightarrow\; (y \in A \cup \emptyset) \\ &\Leftrightarrow\; y \in A \end{aligned}$$

by applying the definition of a set difference, substitution based on the assumed equation $A \cup B = C$, the definition of the union of two sets, the Commutative Law for sentences (1.36), the Distributive Law for sentences (1.44), again (1.36), again the definition of a set difference, then (2.104), substitution based on the previously established equation $A \setminus B = A$, again the definition of the union of two sets, and finally (2.216). As y is arbitrary, we see in light of the Equality Criterion for sets that $C \setminus B = A$ holds. Then, since A, B and C were also arbitrary, it follows that (2.262) holds as claimed. □

Lemma 2.90. *If A is a subset of B, then subtracting A from B and subsequently adjoining A to that difference yields again B, that is,*

$$\forall A, B\,(A \subseteq B \Rightarrow [B \setminus A] \cup A = B). \tag{2.263}$$

Proof. We let A and B be arbitrary sets and assume $A \subseteq B$, so that on the one hand

$$\forall y\,(y \in A \Rightarrow y \in B)$$

holds by definition of a subset, and on the other hand $A \cup B = A$ due to (2.247). We may now verify the truth of the equivalences (letting y be arbitrary)

$$\begin{aligned}
y \in (B \setminus A) \cup A &\Leftrightarrow y \in B \setminus A \lor y \in A \\
&\Leftrightarrow (y \in B \land y \notin A) \lor y \in A \\
&\Leftrightarrow y \in A \lor (y \in B \land y \notin A) \\
&\Leftrightarrow (y \in A \lor y \in B) \land (y \in A \lor y \notin A) \\
&\Leftrightarrow y \in A \cup B \land (y \in A \lor y \notin A) \\
&\Leftrightarrow y \in A \cup B \\
&\Leftrightarrow y \in B
\end{aligned}$$

using the definition of the union of two sets, the definition of a set difference, the Commutative Law for sentences (1.37), the Distributive Law for sentences (1.45), again the definition of the union of two sets, then (1.13) with the fact that the disjunction $y \in A \lor y \notin A$ is a tautology as in (1.10), and finally substitution based on the previously obtained equation $A \cup B = A$. Since y is arbitrary, it now follows with the Equality Criterion for sets that $(B \setminus A) \cup A = B$ is true. As A and B are also arbitrary, we may conclude that the proposed universal sentence holds. □

Proposition 2.91. *Show that the union of any sets A and B can be written as the union of two disjoint sets, that is,*

$$\forall A, B \, \exists C \, (A \cup B = A \cup C \land A \cap C = \emptyset). \tag{2.264}$$

Proof. We let A and B be arbitrary sets and observe for the set $C = B \setminus A$ that $A \cap C = \emptyset$ holds with Lemma 2.35. Furthermore, we obtain for an arbitrary y the true equivalences

$$\begin{aligned}
y \in A \cup C &\Leftrightarrow y \in A \cup (B \setminus A) \\
&\Leftrightarrow y \in A \lor (y \in B \land y \notin A) \\
&\Leftrightarrow (y \in A \lor y \in B) \land (y \in A \lor y \notin A) \\
&\Leftrightarrow y \in A \lor y \in B \\
&\Leftrightarrow y \in A \cup B
\end{aligned}$$

by applying substitution, the definition of the union of two sets together with the definition of a set difference, the Distributive Law for sentences (1.45), then (1.13) with the fact that the disjunction $y \in A \lor y \notin A$ is a tautology according to (1.10), and finally again the definition of the union of two sets. Since y is arbitrary, the equation in $A \cup B = A \cup C$ follows to be true with the Equality Criterion for sets. We thus proved the conjunction in (2.264) for $C = B \setminus A$, and thus the existential sentence. As A and B were arbitrary, we therefore conclude that the proposed sentence is true. $\square$

Note 2.19. The proof of the preceding proposition reveals the truth of the universal sentence

$$\forall A, B\,(A \cup B = A \cup [B \setminus A]). \tag{2.265}$$

2.6.3. Symmetric differences

The following set-theoretical operation, which is defined in terms of the union and the set difference, will be applied later on in the context of 'rings of sets'.

Definition 2.23 (Symmetric difference/Boolean sum). For any sets A and B we call the set

$$A \Delta B = (A \setminus B) \cup (B \setminus A). \tag{2.266}$$

the *symmetric difference* or the *Boolean sum* of A and B.

In case that sets A and B are included in a set X, (2.138) allows for the following equivalent expression of the symmetric difference.

Corollary 2.92. *For any sets A, B and X with $A \subseteq X$ and $B \subseteq X$, it is true that*

$$A \Delta B = (A \cap B^c) \cup (B \cap A^c). \tag{2.267}$$

Recalling that the union of two sets is commutative, we immediately obtain the

Theorem 2.93 (Commutative Law for the symmetric difference). *The symmetric difference of a set A and a set B is identical with the symmetric difference of B and A, that is,*

$$\forall A, B\,(A \Delta B = B \Delta A). \tag{2.268}$$

Proof. Letting A and B be arbitrary sets, we obtain with (2.266) and the Commutative Law for the union of two sets the true equations

$$A \Delta B = (A \setminus B) \cup (B \setminus A) = (B \setminus A) \cup (A \setminus B) = B \Delta A,$$

so that the proposed universal sentence (2.268) follows to be true since A and B were arbitrary. $\square$

The following basic laws for the symmetric difference are readily established.

Exercise 2.42. Show that

a) a set A is equal to its Boolean sum with $\emptyset$, that is,

$$\forall A\,(\emptyset \Delta A = A \,\wedge\, A \Delta \emptyset = A). \tag{2.269}$$

(Hint: Use (2.266), (2.105), (2.102), (2.216), and (2.268).)

b) the symmetric difference of a set A and itself is empty, that is,

$$\forall A\,(A \Delta A = \emptyset), \tag{2.270}$$

(Hint: Apply (2.104) and (2.218).)

c) the Boolean sum of a subset A of a set X and X is equal to the complement of A with respect to X, that is,

$$\forall X, A\,(A \subseteq X \Rightarrow A \Delta X = A^c). \tag{2.271}$$

(Hint: Apply first (2.118) and then (2.266) together with (2.216) as well as (2.131).)

d) the pairwise intersection is distributive over the symmetric difference in the sense that

$$\forall A, B, C\,(A \cap [B \Delta C] = [A \cap B]\,\Delta\,[A \cap C]). \tag{2.272}$$

(Hint: Use (2.266), (2.220) and (2.101).)

Proposition 2.94. *The symmetric difference of two sets A, B and the intersection of A, B are disjoint sets, that is,*

$$\forall A, B\,([A \Delta B] \cap [A \cap B] = \emptyset). \tag{2.273}$$

Proof. Letting A and B be arbitrary sets, we now prove the equation $[A \Delta B] \cap [A \cap B] = \emptyset$ by means of the Equality Criterion for sets. For this purpose, we verify the universal sentence

$$\forall y\,(y \in [A \Delta B] \cap [A \cap B] \Leftrightarrow y \in \emptyset). \tag{2.274}$$

We let y be arbitrary and obtain then the true equivalences

$$\begin{aligned}
&y \in (A\Delta B) \cap (A \cap B) \\
&\quad \Leftrightarrow\ y \in A\Delta B \wedge y \in A \cap B \\
&\quad \Leftrightarrow\ y \in (A \setminus B) \cup (B \setminus A) \wedge (y \in A \wedge y \in B) \\
&\quad \Leftrightarrow\ (y \in A \setminus B \vee y \in B \setminus A) \wedge (y \in A \wedge y \in B) \\
&\quad \Leftrightarrow\ (y \in A \wedge y \in B) \wedge (y \in A \setminus B \vee y \in B \setminus A) \\
&\quad \Leftrightarrow\ y \in A \wedge [y \in B \wedge (y \in A \setminus B \vee y \in B \setminus A)] \\
&\quad \Leftrightarrow\ y \in A \wedge [(y \in B \wedge y \in A \setminus B) \vee (y \in B \wedge y \in B \setminus A)] \\
&\quad \Leftrightarrow\ y \in A \wedge [(y \in B \cap [A \setminus B]) \vee (y \in B \wedge y \in B \wedge y \notin A)] \\
&\quad \Leftrightarrow\ y \in A \wedge [y \in \emptyset \vee (y \in B \wedge y \notin A)] \\
&\quad \Leftrightarrow\ y \in A \wedge [y \in \emptyset \vee y \in B \setminus A] \\
&\quad \Leftrightarrow\ y \in A \wedge y \in \emptyset \cup (B \setminus A) \\
&\quad \Leftrightarrow\ y \in A \wedge y \in B \setminus A \\
&\quad \Leftrightarrow\ y \in A \cap (B \setminus A) \\
&\quad \Leftrightarrow\ y \in \emptyset
\end{aligned}$$

by using the definition of the intersection of two sets, the definition of the symmetric difference together with the definition of the intersection of two sets, the definition of the union of two sets, the Commutative Law for the conjunction, the Associative Law for the conjunction, the Distributive Law for sentences (1.44), the definition of the intersection of two sets together with the definition of a set difference, (2.111) together with the Idempotent Law for the conjunction, again the definition of a set difference, the definition of the union of two sets, (2.216), the definition of the intersection of two sets, and finally again (2.111). Since y is arbitrary, we may therefore conclude that (2.274) holds, so that the Equality Criterion for sets yields the desired equation in (2.273). As A and B were also arbitrary, we finally conclude that the proposition is true. □

Proposition 2.95. *The Boolean sum of two sets A, B is the set difference of the union of A, B and the intersection of A, B, that is,*

$$\forall A, B\,(A\Delta B = [A \cup B] \setminus [A \cap B]). \tag{2.275}$$

Proof. We let A and B be arbitrary sets. We then obtain for an arbitrary

y the true equivalences

$$
\begin{aligned}
&y \in (A \cup B) \setminus (A \cap B) \\
&\quad \Leftrightarrow \; y \in A \cup B \,\wedge\, \neg y \in A \cap B \\
&\quad \Leftrightarrow \; (y \in A \,\vee\, y \in B) \,\wedge\, \neg(y \in A \,\wedge\, y \in B) \\
&\quad \Leftrightarrow \; (y \in A \,\vee\, y \in B) \,\wedge\, (y \notin A \,\vee\, y \notin B) \\
&\quad \Leftrightarrow \; [(y \in A \,\vee\, y \in B) \,\wedge\, y \notin A] \,\vee\, [(y \in A \,\vee\, y \in B) \,\wedge\, y \notin B] \\
&\quad \Leftrightarrow \; [y \notin A \,\wedge\, (y \in A \,\vee\, y \in B)] \,\vee\, [y \notin B \,\wedge\, (y \in A \,\vee\, y \in B)] \\
&\quad \Leftrightarrow \; [(y \notin A \,\wedge\, y \in A) \,\vee\, (y \notin A \,\wedge\, y \in B)] \\
&\quad \; \vee\, [(y \notin B \,\wedge\, y \in A) \,\vee\, (y \notin B \,\wedge\, y \in B)] \\
&\quad \Leftrightarrow \; [(y \in A \,\wedge\, y \notin A) \,\vee\, (y \in B \,\wedge\, y \notin A)] \\
&\quad \; \vee\, [(y \in A \,\wedge\, y \notin B) \,\vee\, (y \in B \,\wedge\, y \notin B)] \\
&\quad \Leftrightarrow \; [y \in A \setminus A \,\vee\, y \in B \setminus A] \,\vee\, [y \in A \setminus B \,\vee\, y \in B \setminus B] \\
&\quad \Leftrightarrow \; [y \in \emptyset \,\vee\, y \in B \setminus A] \,\vee\, [y \in A \setminus B \,\vee\, y \in \emptyset] \\
&\quad \Leftrightarrow \; y \in \emptyset \cup (B \setminus A) \,\vee\, y \in (A \setminus B) \cup \emptyset \\
&\quad \Leftrightarrow \; y \in B \setminus A \,\vee\, y \in A \setminus B \\
&\quad \Leftrightarrow \; y \in A \setminus B \,\vee\, y \in B \setminus A \\
&\quad \Leftrightarrow \; y \in (A \setminus B) \cup (B \setminus A) \\
&\quad \Leftrightarrow \; y \in A \Delta B.
\end{aligned}
$$

applying the definition of a set difference, the definition of the union of two sets together with the definition of the intersection of two sets, De Morgan's Law for sentences (1.51), the Distributive Law for sentences (1.44), the Commutative Law for the conjunction, the Distributive Law (1.44), the Commutative Law for the conjunction, the definition of a set difference, then (2.104), the definition of the union of two sets, (2.216), the Commutative Law for the conjunction, the definition of the union of two sets, and finally the definition of a symmetric difference. As y is arbitrary, we therefore obtain with the Equality Criterion for sets the equation in (2.275). Since A and B were arbitrary, we then further conclude that the proposed sentence is true. □

Corollary 2.96. *The union of two sets A, B is the union of the symmetric difference of A, B and the intersection of A, B, that is,*

$$\forall A, B\,(A \cup B = [A \Delta B] \,\cup\, [A \cap B]). \tag{2.276}$$

Proof. Letting A and B be arbitrary, we first observe the truth of $A \cap B \subseteq$

$A \cup B$ in light of (2.246), which inclusion then implies

$$\begin{aligned} A \cup B &= ([A \cup B] \setminus [A \cap B]) \,\cup\, [A \cap B] \\ &= [A \Delta B] \,\cup\, [A \cap B]. \end{aligned}$$

with (2.263) and (2.275). Since A and B were arbitrary, we therefore conclude that the proposed universal sentence is true. □

Proposition 2.97. *The union of two sets A, B is identical with the symmetric difference of the Boolean sum of A, B and the intersection of A, B, that is,*

$$\forall A, B\, (A \cup B = [A \Delta B]\, \Delta\, [A \cap B]). \tag{2.277}$$

Proof. Let us take arbitrary sets A and B and then notice that $A \Delta B$ and $A \cap B$ are disjoint according to (2.273), so that

$$[A \Delta B] \setminus [A \cap B] = A \Delta B \tag{2.278}$$

$$[A \cap B] \setminus [A \Delta B] = A \cap B \tag{2.279}$$

follow to be true with (2.107). We then obtain the true equations

$$\begin{aligned} [A \Delta B]\, \Delta\, [A \cap B] &= ([A \Delta B] \setminus [A \cap B]) \,\cup\, ([A \cap B] \setminus [A \Delta B]) \\ &= [A \Delta B] \,\cup\, [A \cap B] \\ &= A \cup B \end{aligned}$$

by applying the definition of a symmetric difference, then substitutions based on (2.278) – (2.279), and finally (2.276). Because A and B were arbitrary sets, the corollary therefore follows to be true. □

Corollary 2.98. *The intersection of two sets A, B is the set difference of the union of A, B and the symmetrical difference of A, B, that is,*

$$\forall A, B\, (A \cap B = [A \cup B] \setminus [A \Delta B]). \tag{2.280}$$

Proof. Letting A and B be arbitrary, we see that the equation

$$[A \cap B] \,\cup\, [A \Delta B] = A \cup B$$

holds in view of (2.276) and the Commutative Law for the union of two sets. Observing now that $A \cap B$ and $A \Delta B$ are disjoint according to Proposition 2.273 (using the Commutative Law for the intersection of two sets), we may apply (2.262) to obtain the equation in (2.280). We may then conclude that this equation holds for any A and any B. □

Proposition 2.99. *The set difference of two sets A, B is the symmetric difference of A and the intersection of A, B, that is,*

$$\forall A, B\,(A \setminus B = A\,\Delta\,[A \cap B]). \tag{2.281}$$

Proof. We let A, B and y be arbitrary and observe the truth of the equivalences

$$\begin{aligned}
& y \in A\Delta[A \cap B] \\
& \quad \Leftrightarrow\ y \in [A \setminus (A \cap B)] \cup [(A \cap B) \setminus A] \\
& \quad \Leftrightarrow\ y \in A \setminus (A \cap B)\ \vee\ y \in (A \cap B) \setminus A \\
& \quad \Leftrightarrow\ (y \in A\ \wedge\ \neg y \in A \cap B)\ \vee\ (y \in A \cap B\ \wedge\ y \notin A) \\
& \quad \Leftrightarrow\ (y \in A\ \wedge\ \neg[y \in A\ \wedge y \in B)\ \vee\ ([y \in A\ \wedge\ y \in B]\ \wedge\ y \notin A) \\
& \quad \Leftrightarrow\ (y \in A\ \wedge\ [y \notin A\ \vee\ y \notin B])\ \vee\ ([y \in B\ \wedge\ y \in A]\ \wedge\ y \notin A) \\
& \quad \Leftrightarrow\ ([y \in A\ \wedge\ y \notin A]\ \vee\ [y \in A\ \wedge\ y \notin B])\ \vee\ (y \in B\ \wedge\ [y \in A\ \wedge\ y \notin A]) \\
& \quad \Leftrightarrow\ y \in A\ \wedge\ y \notin B \\
& \quad \Leftrightarrow\ y \in A \setminus B,
\end{aligned}$$

in light of the definition of the symmetric difference, the definition of the union of two sets, the definition of a set difference, the definition of the intersection of two sets, De Morgan's Law for sentences (1.51) together with the Commutative Law for the conjunction, the Distributive Law for sentences (1.44) together with the Associative Law for the conjunction, twice (1.15) with the fact that $y \in A \wedge y \notin A$ and then evidently also $y \in B \wedge [y \in A \wedge y \notin A]$ are contradictions, and finally again the definition of a set difference. Then, the equation $A\Delta(A \cap B) = A \setminus B$ follows to be true with the Equality Criterion for sets, because y is arbitrary. Since A and B were also arbitrary, we may therefore conclude that (2.281) is true. □

In the remainder of this section on the symmetric difference, we introduce some useful laws that involve complements. We begin with the proof that any symmetric difference may be written as the intersection of two unions.

Proposition 2.100. *For any set X and any subsets $A \subseteq X$, $B \subseteq X$ it is true that*

$$A\Delta B = (A \cup B)\ \cap\ (A^c \cup B^c). \tag{2.282}$$

Proof. We let A, B and X be arbitrary and assume $A \subseteq X$ as well as $B \subseteq X$ to be true. Let us first observe that these inclusions imply $A^c \subseteq X$ and $B^c \subseteq X$, respectively, with (2.137); furthermore, the inclusions $A \subseteq X$ and $B \subseteq X$ imply $A \cup B \subseteq X$ with (2.252), and for the same reason the previously established inclusions $A^c \subseteq X$ and $B^c \subseteq X$ imply $A^c \cup B^c \subseteq X$. It then follows from the inclusions $A \cup B \subseteq X$ and $A^c \cup B^c \subseteq X$ that

$$(A \cup B) \cap X = A \cup B, \tag{2.283}$$
$$(A^c \cup B^c) \cap X = A^c \cup B^c \tag{2.284}$$

hold, according to (2.77). We then obtain the equations

$$\begin{aligned}
A\Delta B &= (A \cap B^c) \,\cup\, (B \cap A^c) \\
&= [(A \cap B^c) \cup B] \,\cap\, [(A \cap B^c) \cup A^c] \\
&= [B \cup (A \cap B^c)] \,\cap\, [A^c \cup (A \cap B^c)] \\
&= [(B \cup A) \cap (B \cup B^c)] \,\cap\, [(A^c \cup A) \cap (A^c \cup B^c)] \\
&= [(A \cup B) \cap (B \cup B^c)] \,\cap\, [(A \cup A^c) \cap (A^c \cup B^c)] \\
&= [(A \cup B) \cap X] \,\cap\, [X \cap (A^c \cup B^c)] \\
&= [(A \cup B) \cap X] \,\cap\, [(A^c \cup B^c) \cap X] \\
&= (A \cup B) \,\cap\, (A^c \cup B^c)
\end{aligned}$$

by using (2.267), the Distributive Law for the union of two sets, the Commutative Law for the union of two sets, again the Distributive Law for the union of two sets, again the Commutative Law for the union of two sets, (2.257), the Commutative Law for the intersection of two sets, and finally substitutions based on the previously established equations (2.283) – (2.284). Since A, B and X are arbitrary, we may therefore conclude that proposition is true. □

Exercise 2.43. Show for any set X and any subsets $A \subseteq X$, $B \subseteq X$ that

$$(A\Delta B)^c = (A^c \cup B) \,\cap\, (A \cup B^c). \tag{2.285}$$

(Hint: Apply Corollary 2.92, Theorem 2.88 and (2.136).)

The next result prepares us for the task of establishing the associativity of the symmetric difference.

Exercise 2.44. Show for any set X and any subsets $A \subseteq X$, $B \subseteq X$ that

$$(A\Delta B)\Delta C = (A \cup B \cup C) \cap (A^c \cup B^c \cup C) \cap (A^c \cup B \cup C^c) \cap (A \cup B^c \cup C^c). \tag{2.286}$$

(Hint: Apply (2.282), (2.285), (2.214), (2.220), (2.219), and (2.72).)

Theorem 2.101 (Associative Law for the symmetric difference). *For any set X, the Boolean sum is associative in the sense that*

$$\forall A, B, C\, ([A \subseteq X \,\wedge\, B \subseteq X \,\wedge\, C \subseteq X] \Rightarrow A\Delta[B\Delta C] = [A\Delta B]\Delta C). \tag{2.287}$$

Proof. We let A, B, C and X be arbitrary sets and assume $A \subseteq X$, $B \subseteq X$ as well as $C \subseteq X$ to be true. We then obtain

$$\begin{aligned}
A\Delta(B\Delta C) &= (B\Delta C)\Delta A \\
&= (B \cup C \cup A) \cap (B^c \cup C^c \cup A) \cap (B^c \cup C \cup A^c) \cap (B \cup C^c \cup A^c) \\
&= (A \cup B \cup C) \cap (A \cup B^c \cup C^c) \cap (A^c \cup B^c \cup C) \cap (A^c \cup B \cup C^c) \\
&= (A \cup B \cup C) \cap (A^c \cup B^c \cup C) \cap (A^c \cup B \cup C^c) \cap (A \cup B^c \cup C^c) \\
&= (A\Delta B)\Delta C
\end{aligned}$$

with the Commutative Law for the symmetric difference, (2.286), the Commutative Law for union of two sets and the Commutative Law for the intersection of two sets in connection with the Associative Law for the intersection of two sets (which allows to omit brackets), and again with (2.286). As A, B, C and X were arbitrary sets, we may infer from the truth of these equations the truth of the stated theorem. $\square$

2.7. The Set of Natural Numbers $\mathbb{N}$

In this section, we finalize the construction of the natural numbers.

Axiom 2.5 (Axiom of infinity). There exists a set (system) I which contains 0 and for any of its elements n also the union of n and the singleton formed by n, that is,

$$\exists I\,(0 \in I \,\wedge\, \forall n\,(n \in I \Rightarrow n \cup \{n\} \in I)). \tag{2.288}$$

The existence of such a set gives rise to the following definition and terminology.

Definition 2.24 (Inductive set/successor set, initial element, successor, predecessor). We say that a set I is an *inductive set* or a *successor set* iff

$$0 \in I \,\wedge\, \forall n\,(n \in I \Rightarrow n \cup \{n\} \in I). \tag{2.289}$$

Here, we call 0 the *initial element* of I, and for any $n \in I$ we call the union

$$n^+ = n \cup \{n\} \tag{2.290}$$

the *successor* of n. We then also say that n is a *predecessor* of n^+.

Note 2.20. We speak of 'the' successor of x because the union $n \cup \{n\}$ is a uniquely specified set.

Proposition 2.102. *For any inductive set I it is true that*

$$0^+ = 1 \quad (\in I), \tag{2.291}$$
$$1^+ = 2 \quad (\in I). \tag{2.292}$$

Proof. Letting I be an arbitrary inductive set, we obtain on the one hand the true equations

$$0^+ = 0 \cup \{0\} = \emptyset \cup \{0\} = \{0\} = 1,$$

using (2.290), (2.49), (2.216), and (2.154). Since $0 \in I$ holds according to the first part of the conjunction in (2.289), it follows with the second part that $(1 =)\ 0 \cup \{0\} \in I$, i.e. that $1 \in I$. On the other hand, we obtain

$$1^+ = 1 \cup \{1\} = \{0\} \cup \{1\} = \{0, 1\} = 2,$$

applying (2.290), (2.154), (2.226), and (2.156). Now, the previously established $1 \in I$ implies with the second part of the conjunction in (2.289) that $(2 =)\ 1 \cup \{1\} \in I$, i.e. that $2 \in I$. Because I was arbitrary, we therefore conclude that the proposition is true. $\square$

Combining these findings with the definition of 3 as $2 \cup \{2\}$, we immediately obtain the following result.

Corollary 2.103. *For any inductive set I it is true that*

$$2^+ = 3 \quad (\in I). \tag{2.293}$$

Theorem 2.104. *The following sentences are true.*

a) For any inductive set J there exists a unique set $\mathbb{N}$ such that an element n is in $\mathbb{N}$ iff n is element of J and moreover element of all inductive sets, i.e.

$$\begin{aligned} &\exists! \mathbb{N}\, \forall n\, (n \in \mathbb{N} \\ &\quad \Leftrightarrow [n \in J \wedge \forall I\, ([0 \in I \wedge \forall m\, (m \in I \Rightarrow m^+ \in I)] \Rightarrow n \in I)]). \end{aligned} \tag{2.294}$$

b) The set $\mathbb{N}$ is not empty, that is,

$$\mathbb{N} \neq \emptyset. \tag{2.295}$$

c) The set $\mathbb{N}$ satisfies also

$$\forall n\, (n \in \mathbb{N} \Leftrightarrow \forall I\, ([0 \in I \wedge \forall m\, (m \in I \Rightarrow m^+ \in I)] \Rightarrow n \in I)). \tag{2.296}$$

d) Furthermore, the set $\mathbb{N}$ is inductive, that is,

$$0 \in \mathbb{N} \wedge \forall n\, (n \in \mathbb{N} \Rightarrow n^+ \in \mathbb{N}). \tag{2.297}$$

Proof. Concerning a), we let J be an arbitrary inductive set, using the fact that such a set exists due to the Axiom of Infinity, and we let $\varphi(I)$ be the definite property of I that I is an inductive set, i.e.

$$0 \in I \wedge \forall m\, (m \in I \Rightarrow m^+ \in I)$$

according to (2.289). Due to the Axiom of Specification

$$\exists \mathbb{N}\, \forall n\, (n \in \mathbb{N} \Leftrightarrow [n \in J \wedge \forall I\, (\varphi(I) \Rightarrow n \in I)]) \tag{2.298}$$

is then true, so that we established thusly the existential part of the uniquely existential sentence to be proven. The uniqueness part follows with the Equality Criterion for sets (in analogy to the proof for the intersection of two sets).

Concerning b), we notice first that the unique set $\mathbb{N}$ satisfies, in view of its specification (2.294),

$$\forall n\,(n \in \mathbb{N} \Leftrightarrow [n \in J \,\wedge\, \forall I\,([0 \in I \,\wedge\, \forall m\,(m \in I \Rightarrow m^+ \in I)] \Rightarrow n \in I)]). \tag{2.299}$$

Next, we observe that $0 \in J$ holds by definition of an inductive set. Moreover, letting I be an arbitrary set and assuming $\varphi(I)$ to be true (i.e., assuming I to be inductive), we also see that $0 \in I$ is true; since I is arbitrary, we may therefore conclude that the universal sentence $\forall I\,(\varphi(I) \Rightarrow 0 \in I)$ holds. The conjunction of the previously established $0 \in J$ and the preceding universal sentence now implies $0 \in \mathbb{N}$ due to (2.299). Thus, there exists an element in $\mathbb{N}$, so that the set $\mathbb{N}$ is clearly nonempty.

Concerning c), we take an arbitrary n and prove the first part ('$\Rightarrow$') of the equivalence in (2.296) directly, assuming $n \in \mathbb{N}$ to be true. This assumption implies with (2.299) in particular

$$\forall I\,([0 \in I \,\wedge\, \forall m\,(m \in I \Rightarrow m^+ \in I)] \Rightarrow n \in I), \tag{2.300}$$

proving already the first part of the equivalence. To prove the second part ('$\Leftarrow$'), we now assume (2.300) to be true. Since J was assumed to be an inductive set, it satisfies

$$0 \in J \,\wedge\, \forall m\,(m \in J \Rightarrow m^+ \in J),$$

so that $n \in J$ is implied. Together with (2.300), this further implies $n \in \mathbb{N}$, completing the proof of the equivalence in (2.296). As n was arbitrary, we therefore conclude that c) is also true.

Concerning d), we recall first from the proof of b) that

$$\emptyset \in \mathbb{N}. \tag{2.301}$$

Secondly, to verify

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \in \mathbb{N}), \tag{2.302}$$

we let n be an arbitrary element of $\mathbb{N}$; according to (2.296), $n \in \mathbb{N}$ then implies (2.300) with (2.296). We may prove the universal sentence

$$\forall I\,([0 \in I \,\wedge\, \forall m\,(m \in I \Rightarrow m^+ \in I)] \Rightarrow n^+ \in I). \tag{2.303}$$

Indeed, letting I be an arbitrary inductive set, it follows with (2.300) that $n \in I$ holds, which in turn implies $n^+ \in I$ by definition of an inductive set. As I was arbitrary, we may therefore conclude that (2.303) is true. Consequently, $n^+ \in \mathbb{N}$ follows also to be true in view of (2.296). Since

n was arbitrary, it follows then that the universal sentence (2.302) holds, which shows – together with (2.301) – that $\mathbb{N}$ is inductive.

In the proofs of a) – d) the set J was arbitrary, so that the theorem is in fact true for any such set J. □

We thus completed von Neumann's construction of the set of natural numbers.

Definition 2.25 ((Von Neumann's) set of natural numbers, natural number). We call the set $\mathbb{N}$, which we also symbolize by

$$\{0, 1, 2, \ldots\}, \tag{2.304}$$

the *set of natural numbers*. Thus, we call the elements $n = 0, 1, 2, \ldots$ of $\mathbb{N}$ *natural numbers*.

Note 2.21. We may informally view the set $\mathbb{N}$, due to its specification (2.294), as the intersection of all inductive sets. As this intersection $\mathbb{N}$ would then be a subset of every inductive set due to (2.92), $\mathbb{N}$ could be viewed as the 'smallest' inductive set.

Proposition 2.105. *The following sentences are true.*

a) Any natural number is an element of its successor, that is,

$$\forall n\,(n \in \mathbb{N} \Rightarrow n \in n^+). \tag{2.305}$$

b) Any natural number is a subset of its successor, that is,

$$\forall n\,(n \in \mathbb{N} \Rightarrow n \subseteq n^+). \tag{2.306}$$

Proof. Concerning a), we let n be arbitrary and assume $n \in \mathbb{N}$. Let us first recall that $n^+ = n \cup \{n\}$ holds by definition of a successor. Then, the basic fact $n = n$ implies $n \in \{n\}$ with (2.169), which further implies the disjunction $n \in n \vee n \in \{n\}$ and therefore $n \in n \cup \{n\}$ by definition of the union of a pair. This means $n \in n^+$, and since n is arbitrary, we therefore conclude that a) is true.

Concerning b), we again let n be arbitrary and assume $n \in \mathbb{N}$. By definition of the union of a pair, we have $n \cup \{n\} = \bigcup\{n, \{n\}\}$. Clearly, $n \in \{n, \{n\}\}$ holds by definition of a pair. It then follows with Proposition 2.67 that $n \subseteq \bigcup\{n, \{n\}\}$ is true, which means $n \subseteq n \cup \{n\}$ and thus $n \subseteq n^+$. As n was arbitrary, the therefore conclude that b) also holds, as claimed. □

It is occasionally useful to exclude the number 0 from the set $\mathbb{N}$.

Definition 2.26 (Set of positive natural numbers, positive natural number). We call

$$\mathbb{N}_+ = \{1, 2, \ldots\} = \mathbb{N} \setminus \{0\} \tag{2.307}$$

the *set of positive natural numbers* and the elements of $\mathbb{N}_+$ *positive natural numbers*.

Exercise 2.45. Show that

a) the set of positive natural numbers is a subset of the set of natural numbers, i.e.

$$\mathbb{N}_+ \subseteq \mathbb{N}. \tag{2.308}$$

(Hint: Apply (2.125) to the set difference in (2.307).)

b) the set of natural numbers is the union of the singleton formed by 0 and the set of positive natural numbers, that is,

$$\mathbb{N} = \{0\} \cup \mathbb{N}_+. \tag{2.309}$$

(Hint: Use (2.301) together (2.49) and (2.184), then apply (2.263) and (2.214).)

c) a natural number is 0 or a positive natural number, that is,

$$\forall n \, (n \in \mathbb{N} \Leftrightarrow [n = 0 \, \vee \, n \in \mathbb{N}_+]). \tag{2.310}$$

(Hint: Use (2.18) to (2.309), then Definition 2.19, and finally (2.169).)

We conclude this section with a widely used proof technique based on the inductive nature of the natural numbers.

Theorem 2.106 (Principle of Mathematical Induction). *Any inductive subset M of $\mathbb{N}$ is identical with $\mathbb{N}$, that is,*

$$\forall M \, ([M \subseteq \mathbb{N} \, \wedge \, M \text{ is an inductive set}] \Rightarrow M = \mathbb{N}). \tag{2.311}$$

Proof. To prove the universal sentence we let M be an arbitrary set. Then, to proof the implication directly, we assume that M is inductive and a subset of $\mathbb{N}$. To prove $M = \mathbb{N}$, we show that $M \subseteq \mathbb{N} \wedge \mathbb{N} \subseteq M$; here, we only need to show that $\mathbb{N} \subseteq M$ since the first part of the conjunction is true by assumption. In light of (2.8), we must then show that $\forall y \, (y \in \mathbb{N} \Rightarrow y \in M)$. To prove this universal sentence, we let y be arbitrary. Then, to prove the involved implication directly, we assume $y \in \mathbb{N}$; due to the definition of $\mathbb{N}$, y is an element of every inductive set, thus in particular of M, so that $y \in M$ is true. This proves $\forall y \, (y \in \mathbb{N} \Rightarrow y \in M)$ since y was arbitrary, which means that $\mathbb{N} \subseteq M$ is also true. Consequently, $M = \mathbb{N}$ holds, which completes the proof of the theorem since M is arbitrary. □

We can now summarize the rationale of the proof method we intend to describe.

Proposition 2.107. *Let $\varphi(n)$ be an arbitrary formula and n a free variable with values in the set of natural numbers $\mathbb{N}$. Then, the following sentences are true.*

a) There exists a unique set

$$X = \{n : n \in \mathbb{N} \wedge \varphi(n)\}$$

which contains precisely all the natural numbers n for which $\varphi(n)$ is true, and this set X is a subset of $\mathbb{N}$.

b) If this set X is inductive, then $\varphi(n)$ is true for all natural numbers, that is,

$$X \text{ is an inductive set } \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow \varphi(n)). \tag{2.312}$$

c) If

$$\varphi(0) \tag{2.313}$$

and

$$\forall n\,(n \in \mathbb{N} \Rightarrow [\varphi(n) \Rightarrow \varphi(n^+)]) \tag{2.314}$$

are true, then the set X specified in a) is an inductive set.

Proof. Concerning a), we may apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true uniquely existential sentence

$$\exists! X\,\forall n\,(n \in X \Leftrightarrow [n \in \mathbb{N} \wedge \varphi(n)]). \tag{2.315}$$

Then, the set X satisfies

$$\forall n\,(n \in X \Leftrightarrow [n \in \mathbb{N} \wedge \varphi(n)]). \tag{2.316}$$

To prove $X \subseteq \mathbb{N}$, we verify (applying the definition of a subset) the equivalent

$$\forall n\,(n \in X \Rightarrow n \in \mathbb{N}). \tag{2.317}$$

Fot this purpose, we let n be arbitrary and assume $n \in X$, which then implies $n \in \mathbb{N} \wedge \varphi(n)$ with (2.316). By definition of a conjunction, we have in particular that $n \in \mathbb{N}$ is true. This proves the implication in (2.317), and since n is arbitrary, we therefore conclude that (2.317) holds. We thus proved $X \subseteq \mathbb{N}$.

Concerning b), we prove the implication directly, assuming that X is an inductive set. To prove the consequent, which is a universal sentence, we let n be arbitrary and assume $n \in \mathbb{N}$. Next, we notice that the conjunction of the previously established fact $X \subseteq \mathbb{N}$ and the assumption that X is inductive implies $X = \mathbb{N}$ with the Principle of Mathematical Induction (2.311). Thus, $n \in \mathbb{N}$ implies $n \in X$, which further implies the conjunction $n \in \mathbb{N} \wedge \varphi(n)$ due to (2.316), and therefore in particular $\varphi(n)$. As n is arbitrary, we therefore conclude that the universal sentence to proven holds, which proves the stated implication.

Concerning c), we assume that (2.313) and (2.314) hold. To show that this implies that X is inductive, we verify that X satisfies (2.289), i.e.

$$0 \in X \wedge \forall n\, (n \in X \Rightarrow n^+ \in X). \tag{2.318}$$

To do this, we carry out a proof of a conjunction. Regarding the first part of the conjunction, we observe that the conjunction of the fact $0 \in \mathbb{N}$ and the assumption $\varphi(0)$ implies $\emptyset \in X$ with (2.316). Regarding the second part of the conjunction, which is a universal sentence, we let n be arbitrary, then assume $n \in X$, and show that this implies $n^+ \in X$. Here, $n \in X$ implies with (2.316) that $n \in \mathbb{N}$ and $\varphi(n)$ are both true. Because of the assumption (2.314), $n \in \mathbb{N}$ implies $\varphi(n) \Rightarrow \varphi(n^+)$. Since $\varphi(n)$ is true, it follows that $\varphi(n^+)$ is also true. Since $\mathbb{N}$ is inductive, $n \in \mathbb{N}$ furthermore implies $n^+ \in \mathbb{N}$, so that the conjunction $n^+ \in \mathbb{N} \wedge \varphi(n^+)$ is true. This conjunction then implies $n^+ \in X$ with (2.316). As n was arbitrary, we therefore conclude that the second part of the conjunction (2.318) is true. Thus, X is an inductive set, which proves the implication c). □

Corollary 2.108. *The following implication holds for an arbitrary formula $\varphi(n)$. If (2.313) and (2.314) are true, then $\varphi(n)$ is true for all $n \in \mathbb{N}$.*

Proof. Letting $\varphi(n)$ be an arbitrary formula, the truth of the conjunction of the implications c) and b) in Proposition 2.107 implies the stated implication with the Law of the Hypothetical Syllogism. □

Thus, a proof along these lines can be considered to be a proof of a universal sentence where we seek to show that a given formula is true for all natural numbers.

Method 2.2 (Proof by mathematical induction (for $\mathbb{N}$)). To prove that a given formula $\varphi(n)$ holds for all natural numbers, we show that the so-called *base case* (2.313) and *induction step* (2.314) are true, where $\varphi(n)$ is called the *induction assumption*.

We will apply this method when we could otherwise not prove the given formula via a standard proof of a universal sentence based by simply 'letting n be arbitrary'.

Proposition 2.109. *0 is an element of the successor of any natural number, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow 0 \in n^+). \tag{2.319}$$

Proof. We apply a proof by mathematical induction, where $\varphi(n)$ is given by $0 \in n^+$. To prove the base case $\varphi(0)$, i.e. $0 \in 0^+$, we observe that $0 \in 0^+$ holds in view of (2.305). To prove the inducion step, i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow [0 \in n^+ \Rightarrow 0 \in (n^+)^+]),$$

we let n be arbitrary in $\mathbb{N}$, make the induction assumption $0 \in n^+$, and show that this implies $0 \in (n^+)^+$. Now, we obtain the equations

$$(n^+)^+ = n^+ \cup \{n^+\} = \bigcup\{n^+, \{n^+\}\}$$

using the definition of the successor and the definition of the union of a pair. Since $0 \in n^+$ holds (by the induction assumption) and evidently also $n^+ \in \{n^+, \{n^+\}\}$ (by definition of a pair), it follows that $0 \in \bigcup\{n^+, \{n^+\}\}$ is true by definition of the union of a set system, which yields the desired $0 \in (n^+)^+$ with the previously established equations. Since n is arbitrary, we therefore conclude that the induction step holds, so that the proof by mathematical induction is complete. □

Proposition 2.110. *All natural numbers are subsets of* $\mathbb{N}$*, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow n \subseteq \mathbb{N}). \tag{2.320}$$

Proof. Concerning the base case $(n = 0)$, we observe that $\emptyset$ is a subset of $\mathbb{N}$ due to (2.43) and that $0 = \emptyset$ holds by definition of 0; thus, $0 \subseteq \mathbb{N}$. Concerning the induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption $n \subseteq \mathbb{N}$, and prove $n^+ \subseteq \mathbb{N}$, or equivalently $n \cup \{n\} \subseteq \mathbb{N}$ (using the definition (2.290) of a successor). Let us now observe that the fact $n \in \mathbb{N}$ implies $\{n\} \subseteq \mathbb{N}$ with (2.184). Then, the conjunction of the induction assumption $n \subseteq \mathbb{N}$ and $\{n\} \subseteq \mathbb{N}$ implies $n \cup \{n\} \subseteq \mathbb{N}$ with (2.252). Thus, $n^+ \subseteq \mathbb{N}$ holds, and since n was arbitrary, the induction step follows to be true. This completes the proof by mathematical induction. □

Chapter 3.

Ordered Sets

3.1. Ordered Pairs and Cartesian Products of Two Sets

The concepts of this section will prepare us for the subsequent tasks of establishing certain 'relations' between given objects and algebraic entities.

3.1.1. Ordered pairs, ordered triples and ordered quadruples

We begin with the observation that a given pair $\{A, B\}$ is 'unordered' in the sense that we may list its elements A and B in any 'order', because $\{A, B\}$ and $\{B, A\}$ are identical sets according to Exercise 2.16. To impose an order structure on two given sets A and B, we may – instead of forming directly the pair of A and B – form a certain pair of pairs.

Definition 3.1 (Ordered pair, coordinate). For any A and B we call

$$(A, B) = \{\{A\}, \{A, B\}\} \tag{3.1}$$

the *ordered pair* formed by A and B. Here, we call A the *first* and B the *second coordinate* of (A, B). We also say that a set Z is an *ordered pair* iff there exist sets A and B such that Z constitutes the ordered pair formed by A and B, that is, iff

$$\exists A, B\,(\,Z = (A, B)\,). \tag{3.2}$$

Note 3.1. Consisting of a singleton and a pair, an ordered pair is thus a set system. The order of given sets A and B within the ordered pair (A, B) is retrievable via the characteristic that the first coordinate A is element of both the singleton and the pair within (A, B), and that the second coordinate B arises only in one of these sets.

This ordering property is also reflected by the following condition that two ordered pairs must satisfy in order to be identical, which is qualitatively different from the equality condition with respect to unordered pairs.

Theorem 3.1 (Equality Criterion for ordered pairs). *Two ordered pairs (A,B) and (A',B') are identical iff the first coordinates and the second coordinates are identical, that is,*

$$\forall A,B,A',B'\,((A,B)=(A',B')\Leftrightarrow[A=A'\,\wedge\,B=B']). \tag{3.3}$$

Proof. We let A, B, A' and B' be arbitrary sets and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $(A,B)=(A',B')$ holds. Since the ordered pairs (A,B) and (A',B') are set systems, the intersections and the unions of these ordered pairs are uniquely specified, and we obtain on the one hand

$$\begin{aligned}
\bigcap(A,B) &= \bigcap\{\{A\},\{A,B\}\}\\
&= \{A\}\cap\{A,B\}\\
&= \{A\},\\
\bigcap(A',B') &= \bigcap\{\{A'\},\{A',B'\}\}\\
&= \{A'\}\cap\{A',B'\}\\
&= \{A'\}
\end{aligned}$$

using (3.1), (2.209), and (2.175). On the other hand, we obtain

$$\begin{aligned}
\bigcup(A,B) &= \bigcup\{\{A\},\{A,B\}\}\\
&= \{A\}\cup\{A,B\}\\
&= \{A,B\},\\
\bigcup(A',B') &= \bigcup\{\{A'\},\{A',B'\}\}\\
&= \{A'\}\cup\{A',B'\}\\
&= \{A',B'\}
\end{aligned}$$

by applying (3.1), (2.158), and (2.240). Furthermore, substitution yields then the equations

$$\begin{aligned}
(\{A\}=)\quad \bigcap(A,B) &= \bigcap(A',B') \quad (=\{A'\})\\
(\{A,B\}=)\quad \bigcup(A,B) &= \bigcup(A',B') \quad (=\{A',B'\})
\end{aligned}$$

so that the equations

$$\{A\} = \{A'\}$$
$$\{A, B\} = \{A', B'\}$$

hold. Because of the Equality Criterion for singletons and the Equality Criterion for pairs, the conjunction

$$A = A' \wedge [(A = A' \wedge B = B') \vee (A = B' \wedge B = A')]$$

follows to be true. Therefore, the equation $A = A'$ and the disjunction

$$(A = A' \wedge B = B') \vee (A = B' \wedge B = A')$$

are both true. On the one hand, if the first part $A = A' \wedge B = B'$ of this disjunction holds, then we may infer from this conjunction that $B = B'$ holds besides $A = A'$. On the other hand, if the second part $A = B' \wedge B = A'$ of the preceding disjunction holds, we may infer from the second part of this conjunction and the previously established equation $A = A'$ that $B = A' = A$ is true, so that first part of the preceding conjunction can be written as $(A =)\ B = B'$. Consequently, we have in any case that $A = A'$ and $B = B'$ are true, and thus the conjunction in (3.3) holds, as desired.

To prove the second part ('$\Leftarrow$') of the equivalence in (3.3), we now assume $A = A'$ and $B = B'$ to be both true. Then, substitution based on these equations immediately yields the desired $(A, B) = (A', B')$, which proves already the implication. As A, B, A' and B' were arbitrary, we may therefore conclude that the proposed universal sentence (3.3) is true. □

Theorem 3.2 (Characterization of a uniquely existential sentence with two variables). *Any uniquely existential sentence involving two variables can be equivalently expressed as a uniquely existential sentence with respect to a single variable, in the sense that*

$$\exists! X, Y\, (\varphi(X, Y)) \;\Leftrightarrow\; \exists! Z\, (\exists X, Y\, (Z = (X, Y) \wedge \varphi(X, Y))). \tag{3.4}$$

Proof. Letting $\varphi(X, Y)$ be an arbitrary given formula, we establish the first part ('$\Leftarrow$') of the equivalence directly, assuming $\exists! X, Y\, (\varphi(X, Y))$ to be true. According to Notation 1.4, this implies

$$\begin{aligned} &\exists X, Y\, (\varphi(X, Y)) \\ &\quad \wedge \forall X, Y, X', Y'\, ([\varphi(X, Y) \wedge \varphi(X', Y')] \Rightarrow [X = X' \wedge Y = Y']), \end{aligned} \tag{3.5}$$

whereas the desired consequent is equivalent to

$$\begin{aligned}\exists Z\,(\exists X,Y\,(Z=(X,Y)\,\wedge\,\varphi(X,Y)))\\ \wedge\,\forall Z,Z'\,([\exists X,Y\,(Z=(X,Y)\,\wedge\,\varphi(X,Y))\\ \wedge\,\exists X,Y\,(Z'=(X',Y')\,\wedge\,\varphi(X',Y'))]\Rightarrow Z=Z'),\end{aligned}\tag{3.6}$$

in view of the Criterion for unique existence. Due to the assumed antecedent, there exist constants, say $\bar{X}$ and $\bar{Y}$, such that $\varphi(\bar{X},\bar{Y})$ is satisfied. Forming now the ordered pair $\bar{Z}=(\bar{X},\bar{Y})$, we see that the existential sentence

$$\exists X,Y\,(\bar{Z}=(X,Y)\,\wedge\,\varphi(X,Y))$$

is true, which in turn demonstrates the truth of the existential sentence

$$\exists Z\,(\exists X,Y\,(Z=(X,Y)\,\wedge\,\varphi(X,Y))),$$

proving the existential part of (3.6). Concerning the uniqueness part, we let Z and Z' be arbitrary such that the two existential sentences

$$\begin{aligned}&\exists X,Y\,(Z=(X,Y)\,\wedge\,\varphi(X,Y))\\ &\exists X,Y\,(Z'=(X',Y')\,\wedge\,\varphi(X',Y'))\end{aligned}$$

are satisfied. Thus, there are particular constants $\bar{X}$, $\bar{Y}$, $\bar{X}'$ and $\bar{Y}'$ satisfying $Z=(\bar{X},\bar{Y})$, $\varphi(\bar{X},\bar{Y})$, $Z'=(\bar{X}',\bar{Y}')$ and $\varphi(\bar{X}',\bar{Y}')$. Here, the truth of $\varphi(\bar{X},\bar{Y})$ and $\varphi(\bar{X}',\bar{Y}')$ implies the truth of the equations $\bar{X}=\bar{X}'$ and $\bar{Y}=\bar{Y}'$ with (3.5). Consequently, the Equality Criterion for ordered pairs yields $(\bar{X},\bar{Y})=(\bar{X}',\bar{Y}')$, so that $Z=Z'$ follows to be true via substitutions. Because Z and Z' are arbitrary, we may therefore conclude that the second part of the conjunction in (3.6), which proves the uniqueness part and thus the first part of the equivalence in (3.4).

Regarding the second implication '$\Leftarrow$', we assume now that the uniquely existential sentence with respect to Z is true, so that the equivalent conjunction (3.6) holds as well. We note that the consequent to be proven is equivalent to the conjunction (3.5) as shown by Notation 1.4. The first part of the assumed conjunction gives us particular constants $\bar{Z}$, $\bar{X}$ and $\bar{Y}$ satisfying both $\bar{Z}=(\bar{X},\bar{Y})$ and $\varphi(\bar{X},\bar{Y})$. Thus, the existential sentence $\exists X,Y\,(\varphi(X,Y))$ is true, so that the existential part in (3.5) holds. To prove the uniqueness part, we take arbitrary $\bar{X}$, $\bar{Y}$, $\bar{X}'$ and $\bar{Y}'$, assuming $\varphi(\bar{X},\bar{Y})$ and $\varphi(\bar{X}',\bar{Y}')$ to be true. Defining now the ordered pairs $\bar{Z}=(\bar{X},\bar{Y})$ and $\bar{Z}'=(\bar{X}',\bar{Y}')$, we see that the conjunctions

$$\begin{aligned}\bar{Z}&=(\bar{X},\bar{Y})\,\wedge\,\varphi(\bar{X},\bar{Y})\\ \bar{Z}'&=(\bar{X}',\bar{Y}')\,\wedge\,\varphi(\bar{X}',\bar{Y}')\end{aligned}$$

hold, which in turn give rise to the true existential sentences

$$\exists X, Y\, (\bar{Z} = (X, Y) \wedge \varphi(X, Y)),$$
$$\exists X, Y\, (\bar{Z}' = (X', Y') \wedge \varphi(X', Y')).$$

Due to the second part of (3.6), the conjunction of the preceding existential sentences implies $\bar{Z} = \bar{Z}'$. Then, substitutions give us the equation $(\bar{X}, \bar{Y}) = (\bar{X}', \bar{Y}')$, which further implies $\bar{X} = \bar{X}'$ and $\bar{Y} = \bar{Y}'$ with the Equality Criterion for ordered pairs. Since $\bar{X}$, $\bar{Y}$, $\bar{X}'$ and $\bar{Y}'$ are arbitrary, the second part of the conjunction (3.5) follows therefore to be true, which finding completes the proof of the uniqueness part and thus the proof of the second part of the equivalence in (3.4). □

The following definition demonstrates the principle that is applied to extend the concept of an ordered pair to sets with more than two coordinates.

Notation 3.1 (Ordered triple, ordered quadruple). We call

(1) for any sets A, B, C the ordered pair formed by the ordered pair (A, B) and C, symbolically

$$(A, B, C) = ((A, B), C), \tag{3.7}$$

the *ordered triple* formed by A, B and C. We then refer to A, B, C as the *first*, *second* and *third coordinate* of (A, B, C).

(2) for any sets A, B, C, D the ordered pair formed by the ordered triple (A, B, C) and D, symbolically

$$(A, B, C, D) = ((A, B, C), D) = (((A, B), C), D), \tag{3.8}$$

the *ordered quadruple* formed by A, B, C and D. Here, we say that A, B, C, D are the *first*, *second*, *third* and *fourth coordinate* of (A, B, C, D).

3.1.2. Power sets and Cartesian products of two sets

Before we can define particular sets of ordered pairs, it is necessary to introduce the concept of a *set of subsets* of a given set.

Axiom 3.1 (Axiom of powers). For any set A there exists a set (system) $\mathcal{P}$ which contains every subset of A, that is,

$$\forall A\, \exists \mathcal{P}\, \forall Y\, (Y \subseteq A \Rightarrow Y \in \mathcal{P}). \tag{3.9}$$

In order to establish an unambiguous definition of a set with that property, we now specify those elements in $\mathcal{P}$ which are truly subsets of A.

Proposition 3.3. *The following sentences are true for any set A and any set system $\mathcal{P}$ containing all subsets of A.*

a) There exists a unique set (system) $\mathcal{P}(A)$ such that a set Y is in $\mathcal{P}(A)$ iff Y is in $\mathcal{P}$ and moreover a subset of A, that is,

$$\exists! \mathcal{P}(A)\, \forall Y\, (Y \in \mathcal{P}(A) \Leftrightarrow [Y \in \mathcal{P} \wedge Y \subseteq A]). \tag{3.10}$$

b) The set $\mathcal{P}(A)$ is nonempty, that is,

$$\mathcal{P}(A) \neq \emptyset. \tag{3.11}$$

c) The set $\mathcal{P}(A)$ satisfies

$$\forall Y\, (Y \in \mathcal{P}(A) \Leftrightarrow Y \subseteq A). \tag{3.12}$$

Proof. We let A be an arbitrary set and $\mathcal{P}$ an arbitrary set system containing all subsets of A.

Concerning a), we define $\varphi(Y)$ to be the formula

$$Y \subseteq A$$

and apply the Axiom of Specification to obtain the true existential sentence

$$\exists \mathcal{P}(A)\, \forall Y\, (Y \in \mathcal{P}(A) \Leftrightarrow [Y \in \mathcal{P} \wedge \varphi(Y)]). \tag{3.13}$$

Then, $\mathcal{P}(A)$ exists uniquely in view of the Equality Criterion for sets.

Concerning b), we see in light of (2.43) that $\emptyset \subseteq A$ holds, which then implies also $\emptyset \in \mathcal{P}$ since $\mathcal{P}$ contains every subset of A. Thus, the conjunction $\emptyset \in \mathcal{P} \wedge \emptyset \subseteq A$ holds, so that $\emptyset \in \mathcal{P}(A)$ follows to be true with (3.10). This proves the existence of an element in $\mathcal{P}(A)$, which yields (3.11) according to (2.42).

Concerning c), to show that $\mathcal{P}(A)$ satisfies also (3.12), we let $\bar{Y}$ be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $\bar{Y} \in \mathcal{P}(A)$ holds. Then, this assumption implies with (3.10) in particular $\bar{Y} \subseteq A$, as desired. To prove the second part ('$\Leftarrow$') of the equivalence, we now assume $\bar{Y} \subseteq A$ to be true, so that $\bar{Y} \in \mathcal{P}$ holds in view of the specification of $\mathcal{P}$. Thus, the conjunction $\bar{Y} \in \mathcal{P} \wedge \bar{Y} \subseteq A$ is true, which in turn implies the desired $\bar{Y} \in \mathcal{P}(A)$ with (3.10). As $\bar{Y}$ is arbitrary, we may therefore conclude that the universal sentence (3.12) holds. Since A was also arbitrary, we then further conclude that the proposition is true. $\square$

Definition 3.2 (Power set). For any set A we call the set $\mathcal{P}(A)$ consisting of all the subsets of A in the sense of

$$\forall Y \, (Y \in \mathcal{P}(A) \Leftrightarrow Y \subseteq A).$$

the *power set* of A. This set is also symbolized by

$$\{Y : Y \subseteq A\}. \tag{3.14}$$

Corollary 3.4. *The power set of a set A contains $\emptyset$ and A, that is,*

$$\forall A \, (\emptyset, A \in \mathcal{P}(A)). \tag{3.15}$$

Proof. Letting A be an arbitrary set, we recall from the proof of Proposition 3.3b) that $\emptyset \in \mathcal{P}(A)$ holds. Furthermore, $A \subseteq A$ is true according to (2.10), and therefore $A \in \mathcal{P}(A)$ follows to be true with (3.12). Since A is arbitrary, we therefore conclude that the proposed universal sentence is true. $\square$

Exercise 3.1. Show for any sets A and B that the power set of A is included in the power set of B of A is included in B, that is,

$$\forall A, B \, (A \subseteq B \Rightarrow \mathcal{P}(A) \subseteq \mathcal{P}(B)). \tag{3.16}$$

(Hint: Apply the definition of a subset in connection with (2.13).)

Exercise 3.2. Show that the power set of the empty set is the singleton formed by the empty set, that is,

$$\mathcal{P}(\emptyset) = \{\emptyset\}. \tag{3.17}$$

(Hint: Apply Method 2.1 in connection with (3.12), (2.46) and (2.169).)

Proposition 3.5. *It is true for any set X and any nonempty subset $\mathcal{S}$ of the power set of X that the intersection of the set system $\mathcal{S}$ is an element of the power set of X, that is,*

$$\forall X, \mathcal{S} \, ([\mathcal{S} \subseteq \mathcal{P}(X) \wedge \mathcal{S} \neq \emptyset] \Rightarrow \bigcap \mathcal{S} \in \mathcal{P}(X)). \tag{3.18}$$

Proof. We let X and $\mathcal{S}$ be arbitrary sets, assuming that $\mathcal{S}$ is included in the power set $\mathcal{P}(X)$ and assuming that $\mathcal{S} \neq \emptyset$ holds. Let us observe here that the former assumption implies by definition of a subset

$$\forall A\,(A \in \mathcal{S} \Rightarrow A \in \mathcal{P}(X)). \tag{3.19}$$

Because the desired consequent $\bigcap \mathcal{S} \in \mathcal{P}(X)$ is equivalent to $\bigcap \mathcal{S} \subseteq X$ by definition of a power set, we may apply again the definition of a subset and prove the equivalent universal sentence

$$\forall y\,(y \in \bigcap \mathcal{S} \Rightarrow y \in X). \tag{3.20}$$

Letting $\bar{y}$ be arbitrary and assuming $\bar{y} \in \bigcap \mathcal{S}$ to be true, we obtain now by definition of the intersection of a set system the true universal sentence

$$\forall A\,(A \in \mathcal{S} \Rightarrow \bar{y} \in A). \tag{3.21}$$

Observing now that the initial assumption $\mathcal{S} \neq \emptyset$ implies the existence of a particular element $\bar{A} \in \mathcal{S}$, we obtain on the one hand in view of (3.19) $\bar{A} \in \mathcal{P}(X)$ and therefore $\bar{A} \subseteq X$ (by definition of a power set). On the other hand, $\bar{A} \in \mathcal{S}$ implies with (3.21) $\bar{y} \in \bar{A}$, which in turn implies evidently $\bar{y} \in X$ by virtue of the preceding inclusion. As $\bar{y}$ is arbitrary, we may therefore conclude that the universal sentence (3.20) is true, giving the inclusion $\bigcap \mathcal{S} \subseteq X$ and then also $\bigcap \mathcal{S} \in \mathcal{P}(X)$, as desired. Because X and $\mathcal{S}$ are arbitrary, we may now further conclude that the proposed universal sentence (3.18) holds as well. □

Exercise 3.3. Prove for any set X and any subset $\mathcal{S}$ of the power set of X that the union of the set system $\mathcal{S}$ is in the power set of X, that is,

$$\forall X, \mathcal{S}\,(\mathcal{S} \subseteq \mathcal{P}(X) \Rightarrow \bigcup \mathcal{S} \in \mathcal{P}(X)). \tag{3.22}$$

Definition 3.3 (Covering). We say for any set X and any set $\mathcal{K}$ that $\mathcal{K}$ is a *covering* of X (alternatively, that $\mathcal{K}$ *covers* X) iff

1. $\mathcal{K}$ consists of subsets of X, that is,

   $$\mathcal{K} \subseteq \mathcal{P}(X) \tag{3.23}$$

   and

2. the union of $\mathcal{K}$ equals X, that is,

   $$\bigcup \mathcal{K} = X. \tag{3.24}$$

Corollary 3.6. *It is true for any set X and any subset A of X that the pair formed by A and its complement covers X.*

Proof. Letting X and A be arbitrary sets and assuming $A \subseteq X$ to hold, we obtain $A^c \subseteq X$ with (2.137). Thus, A and A^c are by definition of a power set elements of $\mathcal{P}(X)$, which finding allows us to establish the inclusion $\{A, A^c\} \subseteq \mathcal{P}(X)$ via the definition of a subset. Indeed, letting $Y \in \{A, A^c\}$ be arbitrary, we obtain the disjunction $Y = A \vee Y = A^c$ with the definition of a pair; since $A \in \{A, A^c\}$ and $A^c \in \{A, A^c\}$ are evidently both true, we immediately obtain the desired consequent $Y \in \mathcal{P}(X)$ by means of a proof by cases in connection with corresponding substitutions (which follows then to be true for any Y). Thus, the pair $\{A, A^c\}$ consists of subsets of X, for which we furthermore obtain

$$\bigcup\{A, A^c\} = A \cup A^c = X$$

using the notation for the union of two sets and (2.257). Thus, $\{A, A^c\}$ is by definition a covering of X, where, X and A are arbitrary, so that the proposed universal sentence follows to be true. □

Note 3.2. The proof of the preceding corollary shows that the complement of any element of the power set of a set is also element of that power set, that is,

$$\forall X, A\,(A \in \mathcal{P}(X) \Rightarrow A^c \in \mathcal{P}(X)). \tag{3.25}$$

Given two sets A and B, we can use the concept of a power set to specify the following set of ordered pairs.

Theorem 3.7. *The following sentences are true for any sets A and B.*

a) There exists a unique set (system) $A \times B$ such that a set Y is in $A \times B$ iff Y is in the power set $\mathcal{P}(\mathcal{P}(A \cup B))$ and if there are elements $a \in A$ and $b \in B$ such that Y is the ordered pair formed by a and b, that is,

$$\begin{aligned} &\exists! A \times B\, \forall Y\,(Y \in A \times B \\ &\quad \Leftrightarrow [Y \in \mathcal{P}(\mathcal{P}(A \cup B)) \wedge \exists a, b\,(a \in A \wedge b \in B \wedge (a, b) = Y)]). \end{aligned} \tag{3.26}$$

b) The set $A \times B$ is empty iff A or B is empty, that is,

$$(A = \emptyset \vee B = \emptyset) \Leftrightarrow A \times B = \emptyset. \tag{3.27}$$

c) The set $A \times B$ satisfies

$$\forall a, b\,((a, b) \in A \times B \Leftrightarrow [a \in A \wedge b \in B]). \tag{3.28}$$

Proof. We let A, B be arbitrary sets.

Concerning a), we verify first that any ordered pair $(a, b) = \{\{a\}, \{a, b\}\}$ with $a \in A$ and $b \in B$ is in the power set of the power set of the union of A and B, that is,

$$\forall a, b\,([a \in A \,\wedge\, b \in B] \Rightarrow (a, b) \in \mathcal{P}(\mathcal{P}(A \cup B))). \tag{3.29}$$

Letting a and b be arbitrary, we prove the implication directly by assuming $a \in A$ and $b \in B$ to be both true, from which it evidently follows by definition of the union of a pair that $a, b \in A \cup B$ holds. On the one hand, $a \in A \cup B$ implies

$$\{a\} \subseteq A \cup B \tag{3.30}$$

with (2.184). On the other hand, $a, b \in A \cup B$ implies

$$\{a, b\} \subseteq A \cup B \tag{3.31}$$

with (2.164). Since $A \cup B$ uniquely specifies the power set $\mathcal{P}(A \cup B)$, the two inclusions (3.30) and (3.31) yield

$$\{a\}, \{a, b\} \in \mathcal{P}(A \cup B),$$

and therefore

$$[(a, b) =] \quad \{\{a\}, \{a, b\}\} \subseteq \mathcal{P}(A \cup B),$$

applying again (2.164). The set $\mathcal{P}(A \cup B)$ uniquely specifies the power set $\mathcal{P}(\mathcal{P}(A \cup B))$, so that the preceding inclusion $(a, b) \subseteq \mathcal{P}(A \cup B)$ implies

$$(a, b) \in \mathcal{P}(\mathcal{P}(A \cup B)),$$

which proves the implication in (3.29). Since a and b were arbitrary, we may therefore conclude that the universal sentence (3.29) is true.

Next, we use the Axiom of Specification in connection with the Equality Criterion of sets to obtain the true uniquely existential sentence (3.26). Thus, the set $A \times B$ satisfies

$$\forall Y\,(Y \in A \times B \Leftrightarrow [Y \in \mathcal{P}(\mathcal{P}(A \cup B)) \,\wedge\, \exists a, b\,(a \in A \wedge b \in B \wedge (a, b) = Y)]). \tag{3.32}$$

Concerning b), to prove the first part ('$\Rightarrow$') of the equivalence, we assume

$$A = \emptyset \,\vee\, B = \emptyset \tag{3.33}$$

and show that this implies $A \times B = \emptyset$, i.e. that

$$\forall Y\,(Y \notin A \times B) \tag{3.34}$$

holds (using the definition of the empty set). To prove this universal sentence, we let Y be arbitrary. Next, we demonstrate the truth of the negation

$$\neg\exists a, b\,(a \in A \,\wedge\, b \in B \,\wedge\, (a,b) = Y), \tag{3.35}$$

which we may write equivalently as

$$\neg\exists a, b\,(Y = (a,b) \,\wedge\, [a \in A \,\wedge\, b \in B])$$

by applying (1.36) as well as (1.39), and then also as

$$\forall a, b\,(Y = (a,b) \Rightarrow [a \notin A \,\vee\, b \notin B]), \tag{3.36}$$

applying the Quantifier Negation Law (1.54), then (1.81), and subsequently De Morgan's Law for sentences (1.51). We let a and b be arbitrary such that $Y = (a,b)$ holds. Now, if the first part $A = \emptyset$ of the assumed disjunction (3.33) is true, then $a \notin A\,(= \emptyset)$ follows by definition of the empty set. Consequently, the disjunction $a \notin A \vee b \notin B$ also holds, irrespective of the truth value of $b \notin B$. Similarly, if the second part $B = \emptyset$ of the disjunction (3.33) is true, then we obtain $b \notin B$, and the disjunction $a \notin A \vee b \notin B$ is again true (irrespective of the truth value of $a \notin A$). This proves the implication in (3.36), and since a and b are arbitrary, we may therefore conclude that (3.36) holds, and thus equivalently that (3.35) is true. Thus, the existential sentence in (3.32) is false, and therefore the conjunction in (3.32) is also false, which then gives $\neg Y \in A \times B$ by applying the Law of Contraposition to the equivalence in (3.32). As Y is arbitrary, we may then further conclude that (3.34) holds, which gives $A \times B = \emptyset$ with the definition of the empty set. Thus, the proof of the first part of the equivalence in (3.27) is complete.

We prove the second part ('$\Leftarrow$') by contradiction, assuming $A \times B = \emptyset$ and the negation $\neg[A = \emptyset \vee B = \emptyset]$ to be true. We may write the latter equivalently as $A \neq \emptyset \wedge B \neq \emptyset$ by applying De Morgan's Law for sentences (1.52). This conjunction implies in particular $A \neq \emptyset$, so that there exists an element in A, say $\bar{a}$, because of (2.42). Similarly, the preceding conjunction implies in particular also $B \neq \emptyset$, so that there exists also an element in B, say $\bar{b}$. Then, the ordered pair $\bar{Y} = (\bar{a}, \bar{b})$ is uniquely specified, and it follows with (3.29) that $(\bar{a}, \bar{b}) \in \mathcal{P}(\mathcal{P}(A \cup B))$. Moreover, we showed that there exist elements a and b with $a \in A$, $b \in B$, and with $(a,b) = \bar{Y}$. Consequently, $\bar{Y} \in A \times B$ holds according to (3.32). Now, due to the assumption $A \times B = \emptyset$, we have that $\bar{Y} \notin A \times B$ is also true (by definition of the empty set), so that we obtained the contradiction $\bar{Y} \in A \times B \wedge \bar{Y} \notin A \times B$ according to (1.11). Thus, the proof of the second part of the equivalence in (3.27) is also complete.

Concerning c), we now prove that $A \times B$ satisfies (3.28), letting a and b be arbitrary and assuming $(a, b) \in A \times B$ to be true. This implies with (3.32) in particular that there exist elements, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in A$, $\bar{b} \in B$ and $(\bar{a}, \bar{b}) = (a, b)$ hold. This equation now gives $\bar{a} = a$ and $\bar{b} = b$ with (3.3), so that $\bar{a} \in A$ and $\bar{b} \in B$ yield $a \in A$ and $b \in B$ via substitution. This proves the conjunction in (3.28), so that the proof of the first part of the equivalence is complete.

To prove the second part ('$\Leftarrow$'), we now assume $a \in A$ and $b \in B$ to be true, so that we obtain $(a, b) \in \mathcal{P}(\mathcal{P}(A \cup B))$ with (3.29). Moreover, we then see that the existential sentence in (3.32) also holds, so that (a, b) follows to be an element of $\mathcal{X}$. This completes the proof of the equivalence in (3.28), and since a and b were arbitrary, we may therefore conclude that the universal sentence (3.28) is true.

Then, as A and B were also arbitrary, we may finally conclude that the proposition holds, as claimed. □

Definition 3.4 (Cartesian product of two sets). For any sets A and B we call the set $A \times B$ consisting of all the ordered pairs with first coordinate in A and second coordinate in B in the sense of

$$\forall a, b \, ((a, b) \in A \times B \Leftrightarrow [a \in A \, \wedge \, b \in B]).$$

the *Cartesian product* of A and B, and we symbolize this set also by

$$\{(a, b) : a \in A \, \wedge \, b \in B\}. \tag{3.37}$$

Exercise 3.4. Show for any sets A and B that the Cartesian product $A \times B$ satisfies

$$\forall Y \, (Y \in A \times B \Leftrightarrow \exists a, b \, (a \in A \, \wedge \, b \in B \wedge (a, b) = Y)). \tag{3.38}$$

(Hint: Proceed in analogy to the proof of Theorem 3.7b), using the findings obtained in the proof of Theorem 3.7c).)

Exercise 3.5. The Cartesian product of a singleton $\{a\}$ and a singleton $\{b\}$ is identical with the singleton formed by the ordered pair whose first coordinate is a and whose second coordinate is b, that is,

$$\forall a, b \, (\{a\} \times \{b\} = \{(a, b)\}). \tag{3.39}$$

(Hint: Apply Method 2.1 in connection with (3.38) and (2.169).)

3.1.3. Basic laws for the Cartesian product of two sets

Proposition 3.8. *For any sets A, B, X and Y it is true that, if A is included in X and B is included in Y, then the Cartesian product of A and B is included in the Cartesian product of X and Y, i.e.*

$$(A \subseteq X \wedge B \subseteq Y) \Rightarrow A \times B \subseteq X \times Y. \tag{3.40}$$

Proof. We let A, B, X and Y be arbitrary sets and prove implication directly, assuming that $A \subseteq X$ and $B \subseteq Y$ are both true. To show that this implies $A \times B \subseteq X \times Y$, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall z\, (z \in A \times B \Rightarrow z \in X \times Y). \tag{3.41}$$

Letting $\bar{z}$ be arbitrary and assuming $\bar{z} \in A \times B$ to be true, it then follows by definition of the Cartesian product of two sets that there exist elements, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in A$, $\bar{b} \in B$ and $(\bar{a}, \bar{b}) = \bar{z}$ hold. On the one hand, as the initial assumption $A \subseteq X$ means (by definition of a subset) that the implication $a \in A \Rightarrow a \in X$ is true for any a, we see that the previously obtained $\bar{a} \in A$ then implies $\bar{a} \in X$. On the other hand, the initial assumption $B \subseteq Y$ means (again by definition of a subset) that the implication $b \in B \Rightarrow b \in Y$ holds for all b, so that the previously established $\bar{b} \in B$ implies $\bar{b} \in Y$. We thus showed that there exist a and b such that $a \in X$, $b \in Y$ and $(a, b) = \bar{z}$ are true, with the consequence that $\bar{z} \in X \times Y$ holds by definition of the Cartesian product of two sets. Since $\bar{z}$ is arbitrary, we may therefore conclude that (3.41) is true, which yields $A \times B \subseteq X \times Y$ with the definition of a subset, proving the implication (3.40). Since A, B, X and Y were arbitrary, the proposed universal sentence then follows to be true. □

Proposition 3.9. *For any nonempty sets A, B, X and Y it is true that, if the Cartesian product of A and B is included in the Cartesian product of X and Y, then A is included in X and B is included in Y, i.e.*

$$A \times B \subseteq X \times Y \Rightarrow (A \subseteq X \wedge B \subseteq Y). \tag{3.42}$$

Proof. We let A, B, X and Y be arbitrary sets such that $A \neq \emptyset$, $B \neq \emptyset$, $X \neq \emptyset$ and $Y \neq \emptyset$ hold. Consequently, we obtain the nonempty Cartesian products $A \times B \neq \emptyset$ and $X \times Y \neq \emptyset$ with (3.27) and the Law of Contraposition. Now, to prove the implication directly, we assume $A \times B \subseteq X \times Y$ to be true, so that (3.41) holds by definition of a subset. To prove $A \subseteq X \wedge B \subseteq Y$, we apply the definition of a subset again and verify the equivalent conjunction of the universal sentences

$$\forall a\, (a \in A \Rightarrow a \in X) \tag{3.43}$$

and

$$\forall b\,(b \in B \Rightarrow b \in Y). \tag{3.44}$$

To prove (3.43), we let $\bar{a} \in A$ be arbitrary. Since we initially assumed $B \neq \emptyset$, it follows with (2.42) that there exists an element in B, say $\bar{b}$. Then, the ordered pair $\bar{z} = (\bar{a}, \bar{b})$ exists also. We thus showed that there exist a and b satisfying $a \in A$, $b \in B$ and $(a, b) = \bar{z}$, so that $\bar{z}$ is in $A \times B$ by definition of the Cartesian product of two sets. Here, $\bar{z} \in A \times B$ implies with the assumed $A \times B \subseteq X \times Y$ and with the definition of a subset that $\bar{z} \in X \times Y$ holds. Consequently, there exist (again by definition of the Cartesian product of two sets) elements, say $\bar{x}$ and $\bar{y}$, with $\bar{x} \in X$, $\bar{y} \in Y$ and

$$(\bar{x}, \bar{y}) = \bar{z} \quad [= (\bar{a}, \bar{b})].$$

These equations yield $(\bar{x}, \bar{y}) = (\bar{a}, \bar{b})$ and therefore in particular $\bar{x} = \bar{a}$ with (3.3). In view of this equation, we now see that the previously found $\bar{x} \in X$ implies $\bar{a} \in X$. Since $\bar{a}$ is arbitrary, we may therefore conclude that the universal sentence (3.43) and thus the equivalent $A \subseteq X$ is true.

Regarding (3.43), we take an arbitrary $\bar{\bar{b}} \in B$ and recall the initial assumption $A \neq \emptyset$, so that there is an element in A, say $\bar{\bar{a}}$, according to (2.42). The ordered pair $\bar{\bar{z}} = (\bar{\bar{a}}, \bar{\bar{b}})$ is then also specified. These findings show that there are a and b with $a \in A$, $b \in B$ and $(a, b) = \bar{\bar{z}}$, with the consequence that $\bar{\bar{z}} \in A \times B$ (by definition of the Cartesian product of two sets). This further implies $\bar{z} \in X \times Y$ with the assumed $A \times B \subseteq X \times Y$ (and with the definition of a subset). Therefore, there are (once again by definition of the Cartesian product of two sets) elements, say $\bar{\bar{x}}$ and $\bar{\bar{y}}$, such that $\bar{\bar{x}} \in X$, $\bar{\bar{y}} \in Y$ and

$$(\bar{\bar{x}}, \bar{\bar{y}}) = \bar{\bar{z}} \quad [= (\bar{\bar{a}}, \bar{\bar{b}})].$$

These equations give $(\bar{\bar{x}}, \bar{\bar{y}}) = (\bar{\bar{a}}, \bar{\bar{b}})$ and thus in particular $\bar{\bar{y}} = \bar{\bar{b}}$ because of (3.3), so that the previously established $\bar{\bar{y}} \in Y$ gives $\bar{\bar{b}} \in Y$. As $\bar{\bar{b}}$ was arbitrary, it then follows that the universal sentence (3.43) and thus the equivalent $B \subseteq Y$ also holds.

Since $A \subseteq X$ and $B \subseteq Y$ are both true, the proof of the implication in (3.42) is complete. As A, B, X and Y were arbitrary, the proposition follows then to be true. □

Corollary 3.10. *For any nonempty sets A, B, X and Y it is true that A is included in X and B included in Y iff the Cartesian product of A and B is included in the Cartesian product of X and Y, i.e.*

$$(A \subseteq X \,\wedge\, B \subseteq Y) \Leftrightarrow A \times B \subseteq X \times Y. \tag{3.45}$$

Proof. Letting A, B, X and Y be arbitrary sets and assuming further $A \neq \emptyset$, $B \neq \emptyset$, $X \neq \emptyset$ and $Y \neq \emptyset$ to be true, we see that the first part ('$\Rightarrow$') of the equivalence holds with (3.40) and moreover that the second part ('$\Leftarrow$') holds with (3.42). Since A, B, X and Y are arbitrary, we may therefore conclude that the corollary is true. □

Theorem 3.11 (Equality Criterion for Cartesian products of two sets). *The following equivalence holds for any nonempty sets A, B, X, Y.*

$$(A = X \wedge B = Y) \Leftrightarrow A \times B = X \times Y. \tag{3.46}$$

Proof. We let $A \neq \emptyset$, $B \neq \emptyset$, $X \neq \emptyset$ and $Y \neq \emptyset$ be arbitrary sets. To prove the first part ('$\Rightarrow$') of the equivalence, we assume that $A = X$ and $B = Y$ hold. Applying now (2.22), the former equation $A = X$ implies the truth of $A \subseteq X$ and of $X \subseteq A$, and the latter equation $B = Y$ implies $B \subseteq Y$ and $Y \subseteq B$. Therefore, the two conjunctions $A \subseteq X \wedge B \subseteq Y$ and $X \subseteq A \wedge Y \subseteq B$ are also true, which subsequently imply with (3.45) the truth of $A \times B \subseteq X \times Y$ and of $X \times Y \subseteq A \times B$, respectively. The conjunction of these two inclusions then further implies the desired equality $A \times B = X \times Y$ with (2.22), which proves the first part of the equivalence in (3.46).

To prove the second part ('$\Leftarrow$'), we now assume $A \times B = X \times Y$ to be true, which implies the conjunction of $A \times B \subseteq X \times Y$ and $X \times Y \subseteq A \times B$ with (2.22). In view of (3.45), the first part $A \times B \subseteq X \times Y$ implies the truth of $A \subseteq X$ and of $B \subseteq Y$, and the second part $X \times Y \subseteq A \times B$ the truth of $X \subseteq A$ and of $Y \subseteq B$. Consequently, the conjunctions $A \subseteq X \wedge X \subseteq A$ and $B \subseteq Y \wedge Y \subseteq B$ are both true as well, which yield the two respective equations $A = X$ and $B = Y$ with (2.22), proving the desired conjunction in (3.46).

Thus, the proof of the equivalence (3.46) is complete, and since A, B, X and Y were arbitrary, the theorem follows then to be true. □

Exercise 3.6. Show that the following equivalence holds for any nonempty sets A, B, X and Y.

$$(A \neq X \vee B \neq Y) \Leftrightarrow A \times B \neq X \times Y. \tag{3.47}$$

Lemma 3.12 (Elementary characterization of the complement of a Cartesian product). *For any set X, any subsets A and B of X and any elements a and b of X it is true that the ordered pair formed by a and b is in the complement of $A \times B$ with respect to $X \times X$ if, and only if, a is not an element of A or b is not an element of B, that is,*

$$\begin{aligned} &\forall X, A, B, a, b\,([A \subseteq X \wedge B \subseteq X \wedge a \in X \wedge b \in X] \\ &\quad \Rightarrow [(a,b) \in (A \times B)^c \Leftrightarrow a \notin A \vee b \notin B]). \end{aligned} \tag{3.48}$$

Proof. We let X, A, B, a and b be arbitrary and prove the implication directly, assuming $A \subseteq X$, $B \subseteq X$, $a \in X$ and $b \in X$ to be true. Let us first observe that $A \subseteq X$ and $B \subseteq X$ imply $A \times B \subseteq X \times X$ with (3.40), so that the complement of $A \times B$ with respect to $X \times X$ is defined.

We now prove the first part ('⇒') of the equivalence in (3.48) directly, assuming $(a, b) \in (A \times B)^c$ to be true. This assumption implies by definition of a complement that $(a, b) \in (X \times X) \setminus (A \times B)$ is true, so that the conjunction of $(a, b) \in (X \times X)$ and $(a, b) \notin (A \times B)$ holds, according to the definition of a set difference. Here, the latter implies with (3.28) and the Law of Contraposition $\neg(a \in A \wedge b \in B)$, and therefore the desired disjunction $a \notin A \vee b \notin B$ with De Morgan's Law for sentences (1.51). Thus, the proof of the first part of the equivalence in (3.48) is complete.

To prove the second part ('⇐'), we now assume the disjunction $a \notin A \vee b \notin B$ to be true, which implies the negation $\neg(a \in A \wedge b \in B)$ with De Morgan's Law for sentences (1.51). This negation in turn implies $(a, b) \notin A \times B$ with (3.28) and the Law of Contraposition. Furthermore, introducing the denotation $Y = (a, b)$ and recalling that $a \in X$ and $b \in X$ hold, we see that there exist a and b such that $a \in X$, $b \in X$ and $(a, b) = Y$ are true, so that $Y \in X \times X$ follows to be true with (3.38). Thus, $(a, b) \in X \times X$ and $(a, b) \notin A \times B$ both hold, which conjunction gives $(a, b) \in (X \times X) \setminus (A \times B)$ with the definition of a set difference. Consequently, (a, b) is an element of the complement of $A \times B$ with respect to $X \times X$, so that the proof of the second part of the equivalence in (3.48) is also complete. This in turn proves the implication in (3.48), and since X, A, B, a and b were arbitrary, we may therefore conclude that the proposed universal sentence (3.48) is true. □

Theorem 3.13 (Characterization of the complement of a Cartesian product). *For any set X and any subsets A and B of X it is true that the complement of $A \times B$ with respect to $X \times X$ is identical with the union of the Cartesian products $A^c \times B^c$, $A^c \times B$ and $A \times B^c$ (where the complements are taken with respect to X), i.e.*

$$(A \times B)^c = (A^c \times B^c) \cup (A^c \times B) \cup (A \times B^c). \tag{3.49}$$

Proof. We let X be an arbitrary set and A and B arbitrary subsets of X. Thus, the complements of A and B with respect to X are defined. Furthermore, since $A \subseteq X$ and $B \subseteq X$ imply $A \times B \subseteq X \times X$ with Proposition 3.8, the complement of $A \times B$ with respect to $X \times X$ is also defined. We now consider the two exhaustive cases $(A \times B)^c = \emptyset$ and $(A \times B)^c \neq \emptyset$. The first case $(A \times B)^c = \emptyset$ implies $(X \times X) \setminus (A \times B) = \emptyset$ by definition of a complement, which equation in turn implies $X \times X \subseteq A \times B$ with (2.113) and the Law of Contraposition. Together with the previously established inclusion $A \times B \subseteq X \times X$, this further implies $A \times B = X \times X$ with the Axiom of Extension, and then also the conjunction $A = X \wedge B = X$ with the Identity Criterion for Cartesian products of two sets. We now obtain

$$A^c = X \setminus A \;=\; X \setminus X \;=\; \emptyset,$$
$$B^c = X \setminus B \;=\; X \setminus X \;=\; \emptyset,$$

using the definition of a complement, then substitution based on the equations of the preceding conjunction, and (2.104). Thus, $A^c = B^c = \emptyset$, so that the equations $A^c \times B^c = \emptyset$, $A^c \times B = \emptyset$ and $A \times B^c = \emptyset$ evidently follow to be true with (3.27). Then, we obtain the equations

$$(A^c \times B^c) \cup (A^c \times B) \cup (A \times B^c) = \emptyset \cup \emptyset \cup \emptyset = \emptyset \quad [= (A \times B)^c]$$

by applying substitutions and (2.216), recalling the current case assumption. These equations show that (3.49) holds in the first case.

The second case $(A \times B)^c \neq \emptyset$ shows in light of (2.42) that there exists an element in $(X \times X) \setminus (A \times B)$, say $\bar{z}$. Thus, $\bar{z} \in (X \times X) \setminus (A \times B)$ holds by definition of a complement, and therefore $\bar{z} \in X \times X$ and $\bar{z} \notin A \times B$ are true by definition of a set difference. The former implies by definition of the Cartesian product of two sets that are elements, say $\bar{a}$ and $\bar{b}$, satisfying $\bar{a} \in X$, $\bar{b} \in X$ and $(\bar{a}, \bar{b}) = \bar{z}$. Thus, $(\bar{a}, \bar{b}) \in (A \times B)^c$ holds, which then gives the disjunction $\bar{a} \notin A \vee \bar{b} \notin B$ with Lemma 3.12. Let us now observe that there are three possible cases in which this disjunction is true according to its defining truth table:

1. $\bar{a} \notin A$ is true and $\bar{b} \notin B$ is true,
2. $\bar{a} \notin A$ is true and $\bar{b} \notin B$ is false,
3. $\bar{a} \notin A$ is false and $\bar{b} \notin B$ is true.

In the first case, the conjunctions $\bar{a} \in X \wedge \bar{a} \notin A$ and $\bar{b} \in X \wedge \bar{b} \notin B$ hold, so that $\bar{a} \in A^c$ and $\bar{b} \in B^c$ follow to be true by definition of a set difference and of a complement. Therefore, $(\bar{a}, \bar{b}) \in A^c \times B^c$ follows to be true with (3.28). We thus showed that there exists an element in $A^c \times B^c$, so that $A^c \times B^c \neq \emptyset$ holds according to (2.42). Moreover, the disjunction

$$(\bar{a}, \bar{b}) \in A^c \times B^c \vee (\bar{a}, \bar{b}) \in A^c \times B \vee (\bar{a}, \bar{b}) \in A \times B^c \tag{3.50}$$

is then also true.

In the second case, the conjunction $\bar{a} \in X \wedge \bar{a} \notin A$ and $\bar{b} \in B$ are now evidently true, with the consequence that $\bar{a} \in A^c$ and $\bar{b} \in B$ hold simultaneously. We therefore obtain $(\bar{a}, \bar{b}) \in A^c \times B$ due to (3.28), which shows on the one hand that there is an element in $A^c \times B$, so that $A^c \times B \neq \emptyset$; on the other hand, the disjunction (3.50) is then again true.

Similarly, the third case clearly yields $\bar{a} \in A$ and the conjunction $\bar{b} \in X \wedge \bar{b} \notin B$, so that $\bar{a} \in A$ and $\bar{b} \in B^c$ are both true. Consequently, $(\bar{a}, \bar{b}) \in A \times B^c$ holds, and we now see that there exists an element also in $A \times B^c$, so that $A \times B^c \neq \emptyset$. Clearly, the disjunction (3.50) holds then also in this case.

Since (3.50) holds in any case, this means by definition of the union of two sets that

$$(\bar{a}, \bar{b}) \in A^c \times B^c \cup A \times B^c \cup A \times B^c. \tag{3.51}$$

We thus showed that there exists an element in the preceding union, i.e. that the case assumption $(A \times B)^c \neq \emptyset$ implies $A^c \times B^c \cup A \times B^c \cup A \times B^c \neq \emptyset$.

Based on these findings, we now prove the equation (3.49) by verifying

$$\forall Y \, (Y \in (A \times B)^c \Leftrightarrow Y \in (A^c \times B^c) \cup (A^c \times B) \cup (A \times B^c)). \tag{3.52}$$

To do this, we let Y be arbitrary, and we may prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $Y \in (A \times B)^c$ to be true. Therefore, obtain $Y \in X \times X$ and $Y \notin A \times B$ follow to be true with the definitions of a complement and of a set difference. Here, $Y \in X \times X$ implies with (3.38) that there exist elements, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in X$, $\bar{b} \in X$ and $(\bar{a}, \bar{b}) = Y$ hold. We thus have $(\bar{a}, \bar{b}) \in (A \times B)^c$, which in turn implies $\bar{a} \notin X \vee \bar{b} \notin X$ with (3.48). Then, the three aforementioned cases 1. – 3. evidently apply here for $Y = (\bar{a}, \bar{b})$, and we may follow the same line of reasoning as before to infer the truth of (3.51) for that ordered pair. Thus,

$$Y \in A^c \times B^c \cup A^c \times B \cup A \times B^c. \tag{3.53}$$

is true, completing the proof of the first part of the equivalence in (3.52). To prove the second part ('$\Leftarrow$'), we may now assume (3.53) to be true, which then yields the multiple disjunction

$$Y \in A^c \times B^c \vee Y \in A^c \times B \vee Y \in A \times B^c. \tag{3.54}$$

If the first part $Y \in A^c \times B^c$ of this disjunction is true, then there exist in view of (3.38) elements, say $\bar{a}$ and $\bar{b}$, with $\bar{a} \in A^c$, $\bar{b} \in B^c$ and $(\bar{a}, \bar{b}) = Y$. Here, $\bar{a} \in A^c$ $(= X \setminus A)$ gives $\bar{a} \in X$ and $\bar{a} \notin A$, and similarly $\bar{b} \in B^c$ $(= X \setminus B)$ yields $\bar{b} \in X$ and $\bar{b} \notin B$ (applying again the definitions of a complement and of a set difference). Thus, $A \subseteq X$, $B \subseteq X$, $\bar{a}, \bar{b} \in X$ and the disjunction $\bar{a} \notin A \vee \bar{b} \notin B$ hold, and therefore $(\bar{a}, \bar{b}) \in (A \times B)^c$ follows to be true with (3.48).

If the second part $Y \in A^c \times B$ of the disjunction (3.54) holds, then there are elements, say $\bar{a}'$ and $\bar{b}'$, such that $\bar{a}' \in A^c$, $\bar{b}' \in B$ and $(\bar{a}', \bar{b}') = Y$, where $\bar{a}' \in A^c$ $(= X \setminus A)$ implies the truth of $\bar{a}' \in X$ and $\bar{a}' \notin A$. Consequently, the disjunction $\bar{a}' \notin A \vee \bar{b}' \notin B$ also holds. Furthermore, since we initially assumed $B \subseteq X$, we have that $\bar{b}' \in B$ implies $\bar{b}' \in X$. Then, the simultaneous truth of $A \subseteq X$, $B \subseteq X$, $\bar{a}', \bar{b}' \in X$ and of $\bar{a}' \notin A \vee \bar{b}' \notin B$ implies $(\bar{a}', \bar{b}') \in (A \times B)^c$ again with (3.48).

Similarly, if the third part $Y \in A \times B^c$ of the disjunction (3.54) is true, then there now exist elements, say $\bar{a}''$ and $\bar{b}''$, satisfying $\bar{a}'' \in A$, $\bar{b}'' \in B^c$ and $(\bar{a}'', \bar{b}'') = Y$, where $\bar{b}'' \in B^c$ $(= X \setminus B)$ implies the truth of $\bar{b}'' \in X$ and $\bar{b}'' \notin B$. Then, the disjunction $\bar{a}'' \notin A \vee \bar{b}'' \notin B$ is also true. Moreover, as we initially assumed $A \subseteq X$, we see that $\bar{a}'' \in A$ implies $\bar{a}'' \in X$. Together with $A \subseteq X$, $B \subseteq X$, $\bar{b}'' \in X$ and the preceding disjunction, this gives $(\bar{a}'', \bar{b}'') \in (A \times B)^c$ due to (3.48).

We thus obtain $Y \in (A \times B)^c$ no matter which part of the disjunction (3.54) is true, which proves also the second part of the equivalence in (3.52). As Y is arbitrary, we may therefore conclude that the universal sentence (3.52) holds, which in turn implies the equation (3.49) because of (2.18). This also completes the proof by cases, and since X, A and B were arbitrary sets, we may finally conclude that the theorem is true. □

Proposition 3.14. *If two sets C and D are disjoint, then the Cartesian product of a set A with C and the Cartesian product of a set B with D are also disjoint, that is,*

$$\forall A, B, C, D \, (C \cap D = \emptyset \Rightarrow [A \times C] \cap [B \times D] = \emptyset). \tag{3.55}$$

Proof. We let A, B, C and D be arbitrary sets and prove then the implication by contradiction, assuming $C \cap D = \emptyset$ and $[A \times C] \cap [B \times D] \neq \emptyset$ to be both true. The preceding inequality implies now with (2.42) that there exists an element in $[A \times C] \cap [B \times D]$, say $\bar{y}$. Then, $\bar{y} \in [A \times C] \cap [B \times D]$ implies $\bar{y} \in A \times C$ and $\bar{y} \in B \times D$ by definition of the intersection of two sets. On the one hand, $\bar{y} \in A \times C$ implies by definition of the Cartesian product of two sets that there exist elements, say $\bar{a}$ and $\bar{c}$, with $\bar{a} \in A$, $\bar{c} \in C$ and $(\bar{a}, \bar{c}) = \bar{y}$. On the other hand, $\bar{y} \in B \times D$ implies (again with the Cartesian product of two sets) that there are elements, say $\bar{b}$ and $\bar{d}$, such that $\bar{b} \in B$, $\bar{d} \in D$ and $(\bar{b}, \bar{d}) = \bar{y}$ hold. We thus obtained two expressions for $\bar{y}$, which we may combine via substitution to obtain $[\bar{y} =]$ $(\bar{a}, \bar{c}) = (\bar{b}, \bar{d})$, which further implies $\bar{a} = \bar{b}$ and $\bar{b} = \bar{d}$ with (3.3). In view of the latter equation, we see that the previously established $\bar{c} \in C$ gives $\bar{d} \in C$. Since $\bar{d} \in D$ is also true, it follows (by definition of the intersection of two sets) that $\bar{d} \in C \cap D$ holds. This shows that there exists an element in $C \cap D$, which existential sentence in turn implies $C \cap D \neq \emptyset$ with (2.42), in contradiction to the assumed $C \cap D = \emptyset$. This completes the proof of the implication in (3.55), and since the sets A, B, C, D were arbitrary, the proposed universal sentence finally follows to be true. □

Proposition 3.15. *The Cartesian product is distributive over the union of a pair in the sense that*

$$\forall A, B, C\,(A \times [B \cup C] = [A \times B] \cup [A \times C]). \tag{3.56}$$

Proof. We let A, B and C be arbitrary and apply the Equality Criterion for sets to prove the stated equation. To do this, we verify the equivalent

$$\forall Z\,(Z \in A \times [B \cup C] \Leftrightarrow Z \in [A \times B] \cup [A \times C]), \tag{3.57}$$

letting Z be arbitrary. To prove the first part ('$\Rightarrow$') of the equivalence, we assume $Z \in A \times (B \cup C)$ to hold. This assumption implies with (3.38) that there exist an element of A, say $\bar{a}$, and an element of $B \cup C$, say $\bar{x}$, such that $(\bar{a}, \bar{x}) = Z$ holds. Here, $\bar{x} \in B \cup C$ in turn implies the disjunction

$$\bar{x} \in B \vee \bar{x} \in C \tag{3.58}$$

by definition of the union of two sets. In case the first part of this disjunction is true, the conjunction of $\bar{a} \in A$, $\bar{x} \in B$ and $(\bar{a}, \bar{x}) = Z$ holds, so that $Z \in A \times B$ follows to be true with (3.38). Then, the disjunction $Z \in A \times B \vee Z \in A \times C$ is also true, so that

$$Z \in [A \times B] \cup [A \times C] \tag{3.59}$$

holds by definition of the union of two sets. In case the second part $\bar{x} \in C$ of the disjunction (3.58) is true, we now see that the conjunction of $\bar{a} \in A$, $\bar{x} \in C$ and $(\bar{a}, \bar{x}) = Z$ is true, and we therefore obtain $Z \in A \times C$ again with (3.38). Consequently, the disjunction $Z \in A \times B \vee Z \in A \times C$ is true again, and thus the equivalent (3.59) holds, too. This completes the proof of the first part of the equivalence in (3.57).

We now prove the second part ('$\Leftarrow$') directly, assuming $Z \in [A \times B] \cup [A \times C]$ to be true. This implies (by definition of the union of two sets) that the disjunction

$$Z \in A \times B \vee Z \in A \times C \tag{3.60}$$

holds. On the one hand, if $Z \in A \times B$, then there are elements, say $\bar{a}$ and $\bar{b}$, with $\bar{a} \in A$, $\bar{b} \in B$ and $(\bar{a}, \bar{b}) = Z$. Since $\bar{b} \in B$ is true, the disjunction $\bar{b} \in B \vee \bar{b} \in C$ also holds, so that $\bar{b} \in B \cup C$ holds (by definition of the union of two sets). Thus, there exist elements a and b such that $a \in A$, $b \in B \cup C$ and $(a, b) = Z$, and therefore

$$Z \in A \times [B \cup C] \tag{3.61}$$

follows to be true with (3.38). On the other hand, if the second part $Z \in A \times C$ of the disjunction (3.60) holds, then there exist elements, say $\bar{a}$ and $\bar{c}$, with $\bar{a} \in A$, $\bar{c} \in C$ and $(\bar{a}, \bar{c}) = Z$. Here, $\bar{c} \in C$ implies the truth of the disjunction $\bar{c} \in B \lor \bar{c} \in C$, which evidently means that $\bar{c} \in B \cup C$. These findings show that there are elements a and c with $a \in A$, $c \in B \cup C$ and $(a, c) = Z$, with the consequence that (3.61) holds as before. This proves the second part of the equivalence in (3.57), which is thus true. Since Z is arbitrary, we may therefore conclude that the universal sentence (3.57) holds, which in turn implies the equation in (3.56) with the Equality Criterion for sets. As A, B and C were also arbitrary, we may finally conclude that the proposition is true. □

Exercise 3.7. Show that the Cartesian product is distributive over the union also in the sense that

$$\forall A, B, C\,([A \cup B] \times C = [A \times C] \cup [B \times C]). \tag{3.62}$$

(Hint: Proceed similarly as in the proof of Proposition 3.15.)

Proposition 3.16. *The following universal sentence is true.*

$$\forall A, B, C, D\,([A \cap C] \times [B \cap D] = [A \times B] \cap [C \times D]). \tag{3.63}$$

Proof. We let A, B, C and D be arbitrary sets and verify

$$\forall Z\,(Z \in [A \cap C] \times [B \cap D] \Leftrightarrow Z \in [A \times B] \cap [C \times D]), \tag{3.64}$$

letting Z be arbitrary. We now prove the first part ('$\Rightarrow$') of the equivalence and assume $Z \in [A \cap C] \times [B \cap D]$, so that there exist due to (3.38) an element in $A \cap C$, say $\bar{x}$, and an element in $B \cap D$, say $\bar{y}$, satisfying $(\bar{x}, \bar{y}) = Z$. On the one hand, $\bar{x} \in A \cap C$ yields $\bar{x} \in A$ and $\bar{x} \in C$, and on the other hand, $\bar{y} \in B \cap D$ gives $\bar{y} \in B$ and $\bar{y} \in D$, using the definition of the intersection of two sets. As $\bar{x} \in A$, $\bar{y} \in B$ and $(\bar{x}, \bar{y}) = Z$ are thus true, it follows with (3.38) that $Z \in A \times B$ holds. Similarly, the conjunction of $\bar{x} \in C$, $\bar{y} \in D$ and $(\bar{x}, \bar{y}) = Z$ is also true, so that $Z \in C \times D$. Thus, the conjunction of $Z \in A \times B$ and $Z \in C \times D$ holds, which yields the desired $Z \in [A \times B] \cap [C \times D]$ with the definition of the intersection of two sets.

To prove the second part ('$\Leftarrow$') of the equivalence in (3.64), we assume $Z \in [A \times B] \cap [C \times D]$ to be true, which means (by definition of the intersection of two sets) that $Z \in A \times B$ and $Z \in C \times D$ both hold. The former implies with (3.38) that there are elements of A and B, say $\bar{a}$ and $\bar{b}$, such that $(\bar{a}, \bar{b}) = Z$; similarly, the latter implies the existence of elements of C and D, say of $\bar{c}$ and of $\bar{d}$, with $(\bar{c}, \bar{d}) = Z$. Combining now the two equations for Z, we obtain $(\bar{a}, \bar{b}) = (\bar{c}, \bar{d})$ and therefore $\bar{a} = \bar{c}$ as well as $\bar{b} = \bar{d}$, according to the Equality Criterion for ordered pairs. With these equations, the previously established $\bar{c} \in C$ implies $\bar{a} \in C$, and the previously obtained $\bar{d} \in D$ gives $\bar{b} \in D$. Recalling the truth of $\bar{a} \in A$ and $\bar{b} \in B$, we thus have the true conjunctions $\bar{a} \in A \wedge \bar{a} \in C$ and $\bar{b} \in B \wedge \bar{b} \in D$, which further imply $\bar{a} \in A \cap C$ and $\bar{b} \in B \cap D$, respectively (applying again the definition of the intersection of two sets). Recalling now the equation $(\bar{a}, \bar{b}) = Z$, we now see that there are elements a and b such that $a \in A \cap C$, $b \in B \cap D$ and $(a, b) = Z$ are simultaneously true, with the consequence that $Z \in [A \cap C] \times [B \cap D]$ holds, according to (3.38).

This completes the proof of the equivalence in (3.64), and since Z is arbitrary, we may therefore conclude that the universal sentence (3.64) is true. It then follows from this with the Equality Criterion for sets that the equation in (3.63) holds. Finally, as A, B, C and D were arbitrary sets, we may conclude that the proposed universal sentence (3.63) is true. □

Corollary 3.17. *The Cartesian product is distributive over the intersection in the sense that*

$$\forall A, B, C\, (A \times [B \cap C] = [A \times B] \cap [A \times C]), \tag{3.65}$$
$$\forall A, B, C\, ([A \cap B] \times C = [A \times C] \cap [B \times C]). \tag{3.66}$$

Proof. We first observe that the conjunction of the universal sentences (3.65) and (3.66) is equivalent to

$$\forall A, B, C\, (A \times [B \cap C] = [A \times B] \cap [A \times C] \wedge [A \cap B] \times C = [A \times C] \cap [B \times C]) \tag{3.67}$$

because of the Distributive Law for quantification (1.74). Now, letting A, B and C be arbitrary sets, we obtain the true equations

$$A \times (B \cap C) = (A \cap A) \times (B \cap C) \;=\; [A \times B] \cap (A \times C)$$
$$(A \cap B) \times C = (A \cap B) \times (C \cap C) \;=\; (A \times C) \cap (B \times C)$$

by using (2.60) and (3.64). Since A, B and C were arbitrary, we may therefore conclude that the universal sentence (3.67), and thus the equivalent conjunction of the two proposed universal sentences, is true. □

Proposition 3.18. *The following equations hold for any set X and any subsets A_1, A_2, B_1, B_2 of X.*

$$[A_1 \times (B_1 \setminus B_2)] \cap [(A_1 \setminus A_2) \times (B_1 \cap B_2)] = \emptyset. \tag{3.68}$$
$$[A_1 \times (B_1 \setminus B_2)] \cup [(A_1 \setminus A_2) \times (B_1 \cap B_2)] = (A_1 \times B_1) \setminus (A_2 \times B_2). \tag{3.69}$$

Proof. Letting X, A_1, A_2, B_1 and B_2 be arbitrary sets such that $A_1 \subseteq X$, $A_2 \subseteq X$, $B_1 \subseteq X$ and $B_2 \subseteq X$ are true, we prove first the universal sentence

$$\forall y\,(y \notin [A_1 \times (B_1 \setminus B_2)] \cap [(A_1 \setminus A_2) \times (B_1 \cap B_2)]) \tag{3.70}$$

which will imply the stated equation (3.68) by definition of the empty set. For this purpose, we take an arbitrary y, and we prove then the negation by contradiction, assuming that the negation of that negation holds, so that

$$y \in [A_1 \times (B_1 \setminus B_2)] \cap [(A_1 \setminus A_2) \times (B_1 \cap B_2)]$$

follows to be true with the Double Negation Law. This implies with the definition of the intersection of two sets

$$y \in A_1 \times (B_1 \setminus B_2) \,\wedge\, y \in (A_1 \setminus A_2) \times (B_1 \cap B_2), \tag{3.71}$$

so that $y \in A_1 \times (B_1 \setminus B_2)$ is especially true. According to the definition of the Cartesian product of two sets, there exist then particular elements $\bar{a} \in A_1$ and $\bar{b} \in B_1 \setminus B_2$ with $(\bar{a}, \bar{b}) = y$. Let us observe here that $\bar{b} \in B_1 \setminus B_2$ implies in particular $\bar{b} \notin B_2$ with the definition of a set difference. Because the second part of the conjunction in (3.71) is also true, the preceding equation for y yields via substitution

$$(\bar{a}, \bar{b}) \in (A_1 \setminus A_2) \times (B_1 \cap B_2),$$

so that $\bar{a} \in A_1 \setminus A_2$ and $\bar{b} \in B_1 \cap B_2$ evidently follow to be both true. Clearly, the latter implies in particular $\bar{b} \in B_2$, in contradiction to the previously established negation $\bar{b} \notin B_2$. Thus, the proof of the negation in (3.70) is complete, and as y is arbitrary, we may therefore conclude that the universal sentence (3.70) holds, which gives then the equation (3.68) by definition of the empty set.

To establish the second proposed equation (3.69), we apply the Equality Criterion for sets, letting y be arbitrary. We now obtain the true equivalences

$$
\begin{aligned}
& y \in (A_1 \times B_1) \setminus (A_2 \times B_2) \\
& \Leftrightarrow y \in (A_1 \times B_1) \cap (A_2 \times B_2)^c \\
& \Leftrightarrow y \in (A_1 \times B_1) \cap [[(A_2^c \times B_2^c) \cup (A_2^c \times B_2)] \cup (A_2 \times B_2^c)] \\
& \Leftrightarrow y \in [(A_1 \times B_1) \cap [(A_2^c \times B_2^c) \cup (A_2^c \times B_2)]] \\
& \qquad\qquad \cup [(A_1 \times B_1) \cap (A_2 \times B_2^c)] \\
& \Leftrightarrow y \in [(A_1 \times B_1) \cap (A_2^c \times B_2^c)] \cup [(A_1 \times B_1) \cap (A_2^c \times B_2)] \\
& \qquad\qquad \cup [(A_1 \times B_1) \cap (A_2 \times B_2^c)] \\
& \Leftrightarrow y \in [(A_1 \cap A_2^c) \times (B_1 \cap B_2^c)] \cup [(A_1 \cap A_2^c) \times (B_1 \cap B_2)] \\
& \qquad\qquad \cup [(A_1 \cap A_2) \times (B_1 \cap B_2^c)] \\
& \Leftrightarrow y \in [(A_1 \cap A_2^c) \times (B_1 \cap B_2^c)] \cup [(A_1 \cap A_2) \times (B_1 \cap B_2^c)] \\
& \qquad\qquad \cup [(A_1 \cap A_2^c) \times (B_1 \cap B_2)] \\
& \Leftrightarrow y \in [[(A_1 \cap A_2^c) \cup (A_1 \cap A_2)] \times (B_1 \cap B_2^c)] \\
& \qquad\qquad \cup [(A_1 \cap A_2^c) \times (B_1 \cap B_2)] \\
& \Leftrightarrow y \in [[A_1 \cap (A_2^c \cup A_2)] \times (B_1 \cap B_2^c)] \cup [(A_1 \cap A_2^c) \times (B_1 \cap B_2)] \\
& \Leftrightarrow y \in ([A_1 \cap X] \times (B_1 \setminus B_2)) \cup [(A_1 \setminus A_2) \times (B_1 \cap B_2)] \\
& \Leftrightarrow y \in [A_1 \times (B_1 \setminus B_2)] \cup [(A_1 \setminus A_2) \times (B_1 \cap B_2)]
\end{aligned}
$$

by applying (2.138) where the complement is formed with respect to $X \times X$, then the Characterization of the complement of a Cartesian product (where the complements are now taken with respect to X), the Distributive Law for the intersection of two sets, again the Distributive Law for the intersection of two sets, subsequently (3.63) to each of the three Cartesian products, the Commutative Law for the union of two sets, then (3.62), once again the Distributive Law for the intersection of two sets, then (2.257) together with (2.138), and finally (2.77) in connection with the initial assumption of $A_1 \subseteq X$.

Since y is arbitrary, we may therefore infer from the preceding equivalences the truth of the equation (3.69). As the sets X, A_1, A_2, B_1, and B_2 were arbitrary, we may finally conclude that the proposition holds. □

3.2. Binary Relations

The concept of a 'binary relation' is fundamental to subsequently introduced concepts such as 'orderings', 'equivalence relations', and 'functions'.

Definition 3.5 (Binary relation). We say that a set R is a *binary relation* iff R is a set of ordered pairs, i.e. iff

$$\forall Y\,(Y \in R \Rightarrow \exists a, b\,(Y = (a, b))). \tag{3.72}$$

Proposition 3.19. *Any subset of the Cartesian product of any two sets is a binary relation, that is,*

$$\forall A, B, R\,(R \subseteq A \times B \Rightarrow R \text{ is a binary relation}). \tag{3.73}$$

Proof. Letting A, B and R be arbitrary sets and assuming the inclusion $R \subseteq A \times B$ to be true, we need to show that R satisfies (3.72). To do this, we take an arbitrary set Y and assume that $Y \in R$ is true. This assumption implies now with the preceding inclusion $Y \in A \times B$ by definition of a subset. According to the definition of the Cartesian product of two sets, there are then constants, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in A$, $\bar{b} \in B$ and $(\bar{a}, \bar{b}) = Y$ hold. Thus, the desired existential sentence $\exists a, b\,(Y = (a, b))$ is clearly true, and since Y is arbitrary, we may therefore conclude that R satisfies indeed (3.72). This means that R is a binary relation, and as the sets A, B and Z were arbitrary, we may infer from this the truth of the proposed universal sentence. □

Note 3.3. We then say for any set X that R is a binary relation <u>on</u> X iff R is a subset of the Cartesian product $X \times X$, i.e. iff

$$R \subseteq X \times X. \tag{3.74}$$

Notation 3.2. Instead of $(a, b) \in R$ we also write

$$a\,R\,b. \tag{3.75}$$

In the following, we will usually abbreviate "for any set R such that R is a binary relation" by "for any binary relation".

Let us inspect two simple examples for a binary relation.

Proposition 3.20. *The empty set $\emptyset$ is a binary relation.*

Proof. We verify (3.72) for $R = \emptyset$, i.e.

$$\forall Y\,(Y \in \emptyset \Rightarrow \exists a, b\,(Y = (a, b))). \tag{3.76}$$

For this purpose, we let Y be arbitrary and observe that the antecedent $Y \in \emptyset$ is false by definition of the empty set, so that the implication itself is true. As Y is arbitrary, we may therefore conclude that the universal sentence (3.76) is true, so that $\emptyset$ is a binary relation by definition. $\square$

Exercise 3.8. Show that any binary relation on the empty set is itself empty.
(Hint: Use (3.74), (3.27) and (2.46).)

Proposition 3.21. *For any x and any y it is true that the singleton $\{(x,y)\}$ is a binary relation on $\{x,y\}$.*

Proof. We let x and y be arbitrary and verify

$$\forall Y\,(Y \in \{(x,y)\} \Rightarrow \exists a,b\,(Y = (a,b))). \tag{3.77}$$

For this purpose, we take an arbitrary Y and assume $Y \in \{(x,y)\}$, which implies $Y = (x,y)$ with (2.169). Thus, the existential sentence to be proven is clearly true, and since Y is arbitrary, we may therefore conclude that the universal sentence (3.77) holds. Thus, $\{(x,y)\}$ is a binary relation by definition.

Let us now observe that $x \in \{x,y\}$ and $y \in \{x,y\}$ are true according to (2.151), so that we obtain $\{x\} \subseteq \{x,y\}$ $\{y\} \subseteq \{x,y\}$ with (2.184). These two inclusion now give $\{x\} \times \{y\} \subseteq \{x,y\} \times \{x,y\}$ with Corollary 3.10, where $\{x\} \times \{y\} = \{(x,y)\}$ holds according to (3.39). Applying now substitution based on this equation, the preceding inclusion yields $\{(x,y)\} \subseteq \{x,y\} \times \{x,y\}$, so that $\{(x,y)\}$ is a binary relation on $\{x,y\}$.

As x and y were arbitrary, we may finally conclude that the proposed sentence is true. $\square$

Since ordered triples are structurally ordered pairs for which the first coordinates are themselves ordered pairs, we may view the following kind of relation (which we will consider in greater detail in the context of binary operations) as a special case of a binary relation.

Definition 3.6 (Ternary relation). We say that a set R is a *ternary relation* iff R is a set of ordered triples, that is, iff

$$\forall Y\,(Y \in R \Rightarrow \exists a,b,c\,(Y = (a,b,c))). \tag{3.78}$$

Moreover, we say for any set X that R is a ternary relation <u>on</u> X iff R is a subset of the Cartesian product $(X \times X) \times X$, i.e. iff

$$R \subseteq (X \times X) \times X. \tag{3.79}$$

Exercise 3.9. Verify that the $\emptyset$ is a ternary relation.

(Hint: Use the same arguments as in the proof of Proposition 3.20.)

Exercise 3.10. Show for any x, y and z that the singleton $\{(x, y, z)\}$ is a ternary relation.

(Hint: Proceed in analogy to the proof of Proposition 3.21.)

The next theorem allows us to extract from a given binary relation all the ordered pairs whose first coordinate is element of a given set.

Theorem 3.22. *For any binary relation R and any set A there exists a unique set $R \restriction A$ such that an element Z is in $R \restriction A$ iff Z is in R and moreover if Z is some ordered pair with first coordinate in A, i.e. such that*

$$\forall Z\,(Z \in R \restriction A \Leftrightarrow [Z \in R \,\wedge\, \exists a, b\,(a \in A \,\wedge\, (a, b) = Z)]). \tag{3.80}$$

holds. Then, the set $R \restriction A$ satisfies also

$$\forall a, b\,((a, b) \in R \restriction A \Leftrightarrow [(a, b) \in R \,\wedge\, a \in A]). \tag{3.81}$$

Proof. Letting R be an arbitrary binary relation and A an arbitrary set, we may apply the Axiom of Specification to obtain the true existential sentence

$$\exists R \restriction A\, \forall Z\,(Z \in R \restriction A \Leftrightarrow [Z \in R \,\wedge\, \exists a, b\,(a \in A \,\wedge\, (a, b) = Z)]).$$

It then follows with the Equality Criterion for sets that $R \restriction A$ exists uniquely, that is,

$$\exists! R \restriction A\, \forall Z\,(Z \in R \restriction A \Leftrightarrow [Z \in R \,\wedge\, \exists a, b\,(a \in A \,\wedge\, (a, b) = Z)]). \tag{3.82}$$

We now take arbitrary $\bar{a}$ and $\bar{b}$ and assume first $(\bar{a}, \bar{b}) \in R \restriction A$ to be true, which implies with (3.80) that $(\bar{a}, \bar{b}) \in R$ holds and moreover that there exist constants, say $\bar{\bar{a}}$ and $\bar{\bar{b}}$, such that $\bar{\bar{a}} \in A$ and $(\bar{\bar{a}}, \bar{\bar{b}}) = (\bar{a}, \bar{b})$ are true. The latter equation yields with the Equality Criterion for ordered pairs in particular $\bar{\bar{a}} = \bar{a}$, so that $\bar{\bar{a}} \in A$ gives $\bar{a} \in A$ via substitution. Thus, the conjunction $(\bar{a}, \bar{b}) \in R \wedge \bar{a} \in A$ is true, which proves the first part ('$\Rightarrow$') of the equivalence in (3.81).

To prove the second part ('$\Leftarrow$'), we now assume the conjunction of $(\bar{a}, \bar{b}) \in R$ and $\bar{a} \in A$ to be true. Since the equation $(\bar{a}, \bar{b}) = (\bar{a}, \bar{b})$ also holds, the existential sentence $\exists a, b\,(a \in A \wedge (a, b) = (\bar{a}, \bar{b}))$ is true. Consequently, the conjunction

$$(\bar{a}, \bar{b}) \in R \,\wedge\, \exists a, b\,(a \in A \,\wedge\, (a, b) = (\bar{a}, \bar{b}))$$

holds, which in turn implies $(\bar{a}, \bar{b}) \in R \restriction A$ with (3.80). Thus, the proof of the equivalence in (3.81) is complete, and because a and b are arbitrary, we may infer from this the truth of the universal sentence (3.81).

Since R and A were initially arbitrary, we may therefore conclude that the theorem is true. $\square$

Definition 3.7 (Restriction). For any binary relation R and any set A we call the set $R \upharpoonright A$, also symbolized by

$$\{(a,b) : (a,b) \in R \wedge a \in A\}, \tag{3.83}$$

the *restriction* of R to A.

Corollary 3.23. *For any binary relation R and any set A, it is true that the restriction of R to A is a binary relation included in R.*

Proof. We let R be an arbitrary binary relation and A an arbitrary set. To prove $R \upharpoonright A \subseteq R$, i.e. (applying the definition of a subset)

$$\forall Z\,(Z \in R \upharpoonright A \Rightarrow Z \in R),$$

we let Z be arbitrary and assume $Z \in R \upharpoonright A$ to be true, which assumption implies in particular the desired $Z \in R$ with (3.80). Since Z is arbitrary, the preceding universal sentence follows then to be true, so that $R \upharpoonright A \subseteq R$ holds by definition of a subset. Therefore, the restriction $R \upharpoonright A$ consists of ordered pairs in R and constitutes thus a binary relation. As R and A were also arbitrary, we may finally conclude that the corollary is true. □

Exercise 3.11. Show that the restriction of any binary relation on the empty set to any set is itself empty, that is,

$$\forall R, A\,(R \text{ is a binary relation on } \emptyset \;\Rightarrow\; R \upharpoonright A = \emptyset). \tag{3.84}$$

(Hint: Apply Exercise 3.8, Corollary 3.23, and Proposition 2.13.)

Exercise 3.12. Show that the restriction of any binary relation R to the empty set is itself empty, that is,

$$\forall R\,(R \text{ is a binary relation} \;\Rightarrow\; R \upharpoonright \emptyset = \emptyset). \tag{3.85}$$

(Hint: Use (2.39), Method 1.12, and (3.80).)

Proposition 3.24. *For any set X and any binary relation R on X, the restriction of R to X is identical with R, that is,*

$$\forall X, R\,(R \subseteq X \times X \Rightarrow R \upharpoonright X = R). \tag{3.86}$$

Proof. We let X be an arbitrary set and R an arbitrary binary relation on X, i.e. we let R be an arbitrary subset of the Cartesian production $X \times X$. To prove the equation $R \upharpoonright X = R$, we verify that $R \upharpoonright X \subseteq R$ and $R \subseteq R \upharpoonright X$ are both true (which will then imply the desired equation with the Axiom of Extension). Clearly, the first part $R \upharpoonright X \subseteq R$ of this conjunction is true because of Corollary 3.23. To prove the second part $R \subseteq R \restriction X$, we apply the definition of a subset and verify

$$\forall Z\,(Z \in R \Rightarrow Z \in R \restriction X). \tag{3.87}$$

To do this, we let Z be arbitrary and assume $Z \in R$ to be true, which implies on the one hand $Z \in X \times X$ with the assumed inclusion $R \subseteq X \times X$ (applying again the definition of a subset). On the other hand, $Z \in R$ implies by definition of a binary relation that there exist elements, say $\bar{a}$ and $\bar{b}$, such that $Z = (\bar{a}, \bar{b})$ holds. With this, $Z \in R$ implies $(\bar{a}, \bar{b}) \in R$, and $Z \in X \times X$ implies $(\bar{a}, \bar{b}) \in X \times X$. It then follows with the definition of a Cartesian product that there are elements, say $\bar{a}'$ and $\bar{b}'$, with $\bar{a}' \in X$, $\bar{b}' \in X$ and $(\bar{a}', \bar{b}') = (\bar{a}, \bar{b})$. The latter equation implies in particular $\bar{a}' = \bar{a}$ with the Equality Criterion for ordered pairs, so that $\bar{a}' \in X$ gives $\bar{a} \in X$ after substitution. In view of these findings, the sentence

$$(\bar{a}, \bar{b}) \in R \wedge \exists a, b\,(a \in X \wedge (a, b) = (\bar{a}, \bar{b}))$$

is evidently true, so that $(\bar{a}, \bar{b}) \in R \restriction X$ follows to be true with the definition of a restriction. This finally implies the desired $Z \in R \restriction X$ with the previously established equation $Z = (\bar{a}, \bar{b})$. Since Z is arbitrary, we may therefore conclude that (3.87) holds, which yields $R \subseteq R \restriction X$ by definition of a subset. The conjunction of this inclusion and the already proved $R \restriction X \subseteq R$ then gives the equation $R \restriction X = R$ with the Axiom of Extension. As X and R were arbitrary, it follows that the proposition is true. □

Exercise 3.13. Show that any subset R of the Cartesian product of any two sets X and Y is identical with the restriction of R to X, that is,

$$\forall X, R\,(R \subseteq X \times Y \Rightarrow R \restriction X = R). \tag{3.88}$$

(Hint: Proceed in analogy to the proof of Proposition 3.24, recalling Proposition 3.19.)

Proposition 3.25. *For any binary relation R it is true that, if a set A is included in a set B, then the restriction of R to A is included in the restriction of R to B, that is,*

$$\forall R, A, B\,(R \text{ is a binary relation } \Rightarrow [A \subseteq B \Rightarrow R \restriction A \subseteq R \restriction B]). \tag{3.89}$$

Proof. We let R, A and B be arbitrary sets, assume that R is a binary relation, and then we assume furthermore that $A \subseteq B$ holds, that is (by definition of a subset)

$$\forall y\,(y \in A \Rightarrow y \in B). \tag{3.90}$$

To verify $R \upharpoonright A \subseteq R \upharpoonright B$, we prove the equivalent

$$\forall Z\,(Z \in R \upharpoonright A \Rightarrow Z \in R \upharpoonright B). \tag{3.91}$$

To do this, we let Z be arbitrary and assume that $Z \in R \upharpoonright A$ holds, which implies by definition of a restriction $Z \in R$ and moreover that there exist elements, say $\bar{a}$ and $\bar{b}$, with $\bar{a} \in A$ and $(\bar{a}, \bar{b}) = Z$. Here, $\bar{a} \in A$ implies $\bar{a} \in B$ with (3.90); thus, $\bar{a} \in B$ and $(\bar{a}, \bar{b}) = Z$ are both true, which shows that the existential sentence

$$\exists a, b\,(a \in B \,\wedge\, (a, b) = Z)$$

holds. The conjunction of this and the previously established $Z \in R$ then implies the desired $Z \in R \upharpoonright B$ (with the definition of a restriction). Since Z is arbitrary, we may therefore conclude that (3.91) holds, so that $R \upharpoonright A \subseteq R \upharpoonright B$ is indeed true. As R, A and B were also arbitrary, it then follows that the proposed universal sentence (3.89) holds. □

We now establish two characteristic sets which collect, respectively, the first and the second coordinates of a binary relation.

Theorem 3.26. *The following sentences hold for any binary relation R.*

a) There exists a unique set $\mathrm{dom}(R)$ *such that an element a is in* $\mathrm{dom}(R)$ *iff a is in the union of the union of R and moreover if there is an element b such that the ordered pair formed by a and b is in R, i.e.*

$$\exists!\mathrm{dom}(R)\ \forall a\,(a \in \mathrm{dom}(R) \Leftrightarrow [a \in \bigcup\bigcup R \wedge \exists b\,((a, b) \in R)]). \tag{3.92}$$

b) The set $\mathrm{dom}(R)$ *satisfies also*

$$\forall a\,(a \in \mathrm{dom}(R) \Leftrightarrow \exists b\,((a, b) \in R)). \tag{3.93}$$

Proof. Concerning a), we let R be an arbitrary binary relation and use then the Axiom of Specification to obtain the true existential sentence

$$\exists \mathrm{dom}(R)\ \forall a\,(a \in \mathrm{dom}(R) \Leftrightarrow [a \in \bigcup\bigcup R \,\wedge\, \exists b\,((a, b) \in R)]).$$

Then, we may apply the Equality Criterion for sets to establish the unique existence of $\mathrm{dom}(R)$. Thus, the set $\mathrm{dom}(R)$ satisfies

$$\forall a\,(a \in \mathrm{dom}(R) \Leftrightarrow [a \in \bigcup\bigcup R \,\wedge\, \exists b\,((a, b) \in R)]). \tag{3.94}$$

Concerning b), we let a be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $a \in \mathrm{dom}(R)$ to be true, so that the existential sentence $\exists b\,((a,b)\in R)$ to be proven follows in particular to be true with (3.94).

To prove the second part ('$\Leftarrow$') of the equivalence in (3.93), we assume that there is an element, say $\bar{b}$, such that $(a,\bar{b})\in R$ is true. We may write the latter also as $\{\{a\},\{a,\bar{b}\}\}$, using the notation for an ordered pair. Then, $\bigcup R$ evidently contains by definition of the union of a set system the elements of $\{\{a\},\{a,\bar{b}\}\}$, namely $\{a\}$ and $\{a,\bar{b}\}$. Thus, we have in particular $\{a\}\in\bigcup R$, so that $\bigcup\bigcup R$ contains (again by definition of the union of a set system) the element of $\{a\}$, namely a. We now arrived at the desired $a\in\bigcup\bigcup R$, which implies together with the assumed existential sentence $\exists b\,((a,b)\in R)$ because of (3.94) that $a\in\mathrm{dom}(R)$ holds. This completes the proof of the implication '$\Leftarrow$' and thus the proof of the equivalence in (3.93). Since a is arbitrary, we therefore conclude that the universal sentence (3.93) is true.

As R was arbitrary in the proofs of a) and b), we may therefore conclude that the theorem is true. □

Definition 3.8 (Domain). For any binary relation R we call the set $\mathrm{dom}(R)$ consisting of the first coordinates of the ordered pairs in R in the sense that

$$\forall a\,(a\in\mathrm{dom}(R)\Leftrightarrow\exists b\,((a,b)\in R))$$

the *domain* of R, and we symbolize this set also by

$$\{a:\exists b\,((a,b)\in R)\}. \tag{3.95}$$

Corollary 3.27. *For any binary relation R the domain of R is element of the power set of the union of the union of R, that is,*

$$\mathrm{dom}(R)\in\mathcal{P}(\bigcup\bigcup R). \tag{3.96}$$

Proof. Letting R be arbitrary and assuming R to be a binary relation, we see in light of (3.94) that $a\in\mathrm{dom}(R)$ implies in particular $a\in\bigcup\bigcup R$ for any a, so that

$$\mathrm{dom}(R)\subseteq\bigcup\bigcup R \tag{3.97}$$

holds by definition of a subset. Then, (3.96) follows to be true by definition of a power set. Since R was arbitrary, we may therefore conclude that the proposed universal sentence holds. □

Proposition 3.28. *For any set X and any binary relation R on X, it is true that the domain of R is included in X, that is,*

$$\forall X,R\,(R\subseteq X\times X\Rightarrow\mathrm{dom}(R)\subseteq X). \tag{3.98}$$

Proof. We let X be an arbitrary set and R an arbitrary binary relation on X, i.e. an arbitrary subset of $X \times X$. To prove the inclusion $\mathrm{dom}(R) \subseteq X$, we verify

$$\forall a\,(a \in \mathrm{dom}(R) \Rightarrow a \in X). \tag{3.99}$$

To verify this universal sentence, we let $\bar{a}$ be arbitrary and assume $\bar{a} \in \mathrm{dom}(R)$ to be true. By definition of a domain, this assumption implies that there exists an element, say $\bar{b}$, such that $(\bar{a}, \bar{b}) \in R$ holds. This further implies $(\bar{a}, \bar{b}) \in X \times X$ with the assumed $R \subseteq X \times X$, applying the definition of a subset. It then follows with the definition of a Cartesian product in particular that $\bar{a} \in X$ is true, which proves the implication in (3.99). Since a is arbitrary, we may therefore conclude that (3.99) holds, which yields $\mathrm{dom}(R) \subseteq X$ with the definition of a subset. As X and R were also arbitrary, it follows that the proposed universal sentence (3.98) is true. □

Proposition 3.29. *It is true for any a and any b that the domain of the binary relation $\{(a, b)\}$ is identical with the singleton formed by a, that is,*

$$\forall a, b\,(\mathrm{dom}(\{(a, b)\}) = \{a\}). \tag{3.100}$$

Proof. We let $\bar{a}$ and $\bar{b}$ be arbitrary and prove the stated equation by means of the Equality Criterion for sets, by verifying

$$\forall x\,(x \in \mathrm{dom}(\{(\bar{a}, \bar{b})\}) \Leftrightarrow x \in \{\bar{a}\}). \tag{3.101}$$

We take an arbitrary $\bar{x}$, and we assume first $\bar{x} \in \mathrm{dom}(\{(\bar{a}, \bar{b})\})$ to be true. By definition of a domain, there is then a particular $\bar{\bar{b}}$ such that $(\bar{x}, \bar{\bar{b}}) \in \{(\bar{a}, \bar{b})\}$ holds. Consequently, we obtain $(\bar{x}, \bar{\bar{b}}) = (\bar{a}, \bar{b})$ with (2.169), which equation yields especially $\bar{x} = \bar{a}$ with the Equality Criterion for ordered pairs, and this equation implies the desired $\bar{x} \in \{\bar{a}\}$ with (2.169).

We now assume $\bar{x} \in \{\bar{a}\}$ to be true, which gives $\bar{x} = \bar{a}$ again with (2.169). As $(\bar{a}, \bar{b}) \in \{(\bar{a}, \bar{b})\}$ holds according to (2.153), we obtain $(\bar{x}, \bar{b}) \in \{(\bar{a}, \bar{b})\}$ via substitution, which shows that the existential sentence $\exists b((\bar{x}, b) \in \{(\bar{a}, \bar{b})\})$ is true. Consequently, we obtain $\bar{x} \in \mathrm{dom}(\{(\bar{a}, \bar{b})\})$ by definition of a domain, as desired. Since $\bar{x}$ is arbitrary, we may therefore conclude that the universal sentence (3.101) is true, so that the equation in (3.100) holds indeed. Then, as $\bar{a}$ and $\bar{b}$ are also arbitrary, the proposed sentence follows to be true. □

Proposition 3.30. *If the domain of a binary relation R and a set A are not disjoint, then the restriction of R to A is nonempty, i.e.*

$$\forall R, A\,([R \text{ is a binary relation } \wedge \mathrm{dom}(R) \cap A \neq \emptyset] \Rightarrow R \upharpoonright A \neq \emptyset). \tag{3.102}$$

Proof. We let R and A be arbitrary sets such that R is a binary relation and such that $\mathrm{dom}(R) \cap A \neq \emptyset$ holds. Consequently, there exists an element in $\mathrm{dom}(R) \cap A$, say $\bar{a}$ (according to Proposition 2.11). It then follows with the definition of the intersection of two sets that $\bar{a} \in \mathrm{dom}(R)$ and $\bar{a} \in A$ are both true. The former finding implies by definition of a domain that there exists an element, say $\bar{b}$, such that $(\bar{a}, \bar{b}) \in R$ holds. Thus, there are a and b satisfying $a \in A$ and $(\bar{a}, \bar{b}) = (a, b)$, which existential sentence implies – together with $(\bar{a}, \bar{b}) \in R$ – that $(\bar{a}, \bar{b}) \in R \restriction A$ holds, using (3.80). Thus, there exists an element in $R \restriction A$, so that this restriction is evidently nonempty, proving the implication in (3.102). Since R and A were arbitrary sets, we may therefore conclude that the proposed universal sentence is true. □

Exercise 3.14. Show for any set X and any binary relation R with domain X that the restriction of R to X is identical with R, that is,

$$\forall X, R\,([R \text{ is a binary relation } \wedge \mathrm{dom}(R) = X] \Rightarrow R \restriction X = R). \quad (3.103)$$

(Hint: Proceed similarly to the proof of Proposition 3.24, applying now the definition of a domain instead of the definition of a Cartesian product.)

Exercise 3.15. Show that

a) the domain of the restriction of any binary relation to any set is included in that set, that is,

$$\forall R, A\,(R \text{ is a binary relation } \Rightarrow \mathrm{dom}(R \restriction A) \subseteq A). \quad (3.104)$$

b) the domain of the restriction of any binary relation to any subset of the domain of the binary relation includes the subset, that is,

$$\forall R, A\,([R \text{ is a binary relation } \wedge A \subseteq \mathrm{dom}(R)] \Rightarrow A \subseteq \mathrm{dom}(R \restriction A)). \quad (3.105)$$

Corollary 3.31. *It is true that the domain of the restriction of any binary relation to any subset of its domain includes the subset, that is,*

$$\forall R, A\,([R \text{ is a binary relation } \wedge A \subseteq \mathrm{dom}(R)] \Rightarrow \mathrm{dom}(R \restriction A) = A). \quad (3.106)$$

Proof. We let R and A be arbitrary sets, assuming R to be a binary relation and assuming now in addition $A \subseteq \mathrm{dom}(R)$ to hold. On the one hand, the assumption that R is a binary relation implies with Exercise 3.15a) the inclusion $\mathrm{dom}(R \restriction A) \subseteq A$. On the other hand, the assumed antecedent implies with Exercise 3.15b) the inclusion $A \subseteq \mathrm{dom}(R \restriction A)$. These two inclusions gives us then with the Axiom of Extension the desired equation $\mathrm{dom}(R \upharpoonright A) = A$. Since R and A were arbitrary, the corollary follows therefore to be true. □

In analogy to the domain, we may obtain the set of all second coordinates of a binary relation.

Theorem 3.32. *The following sentences hold for any binary relation R.*

a) *There exists a unique set* $\mathrm{ran}(R)$ *such that an element b is in* $\mathrm{ran}(R)$ *iff b is in the union of the union of R and moreover if there is an element a such that the ordered pair formed by a and b is in R, i.e.*

$$\exists!\mathrm{ran}(R)\, \forall b\, (b \in \mathrm{ran}(R) \Leftrightarrow [b \in \bigcup \bigcup R \wedge \exists a\, ((a, b) \in R)]). \quad (3.107)$$

b) *The set* $\mathrm{ran}(R)$ *satisfies also*

$$\forall b\, (b \in \mathrm{ran}(R) \Leftrightarrow \exists a\, ((a, b) \in R)). \quad (3.108)$$

Exercise 3.16. Prove Theorem 3.32.
(Hint: Proceed in analogy to the proof of Theorem 3.26.)

Definition 3.9 (Range). For any binary relation R we call the set $\mathrm{ran}(R)$ consisting of the second coordinates of the ordered pairs in R in the sense that

$$\forall b\, (b \in \mathrm{ran}(R) \Leftrightarrow \exists a\, ((a, b) \in R))$$

the *range* of R, and we symbolize this set also by

$$\{b : \exists a\, ((a, b) \in R)\}. \quad (3.109)$$

Exercise 3.17. Show for any a and any b that the range of the binary relation $\{(a, b)\}$ is identical with the singleton formed by b, that is,

$$\forall a, b\, (\mathrm{ran}(\{(a, b)\}) = \{b\}). \quad (3.110)$$

Proposition 3.33. *Any binary relation R is included in the Cartesian product of its domain and its range, i.e.*

$$R \subseteq \mathrm{dom}(R) \times \mathrm{ran}(R). \quad (3.111)$$

Proof. We let R be an arbitrary set and assume that R is a binary relation. We now prove the stated inclusion by verifying the equivalent (using the definition of a subset)

$$\forall Y\, (Y \in R \Rightarrow Y \in \mathrm{dom}(R) \times \mathrm{ran}(R)). \quad (3.112)$$

We let Y be arbitrary and assume $Y \in R$ to be true. Then, by definition of a binary relation, there are elements, say $\bar{a}$ and $\bar{b}$, such that $Y = (\bar{a}, \bar{b})$ holds. Thus, $Y \in R$ gives $(\bar{a}, \bar{b}) \in R$ via substitution. This finding shows firstly that there exists an element b satisfying $(\bar{a}, b) \in R$, so that $\bar{a} \in \mathrm{dom}(R)$ follows to be true by definition of a domain; secondly, we see that there is an element a such that $(a, \bar{b}) \in R$ holds, with the consequence that $\bar{b} \in \mathrm{ran}(R)$ is true by definition of a range. Thus, the conjunction $\bar{a} \in \mathrm{dom}(R) \wedge \bar{b} \in \mathrm{ran}(R)$ holds, which in turn implies $[Y =]\ (\bar{a}, \bar{b}) \in \mathrm{dom}(R) \times \mathrm{ran}(R)$ with the definition of the Cartesian product of two sets. This completes the proof of the implication in (3.112), and since Y is arbitrary, we may therefore conclude that the universal sentence (3.112) holds. By definition of a subset, the inclusion (3.111) is then true. As R was initially arbitrary, we may finally conclude that the proposition holds. □

Proposition 3.34. *If a binary relation R is included in a binary relation S, then the range of R is included in the range of S, that is,*

$$\begin{aligned}&\forall R, S\,([R \text{ is a binary relation } \wedge\ S \text{ is a binary relation}]\\ &\quad \Rightarrow [R \subseteq S \Rightarrow \mathrm{ran}(R) \subseteq \mathrm{ran}(S)]).\end{aligned} \tag{3.113}$$

Proof. We let R and S be arbitrary binary relations and then assume $R \subseteq S$, that is (using the definition of a subset),

$$\forall z\,(z \in R \Rightarrow z \in S), \tag{3.114}$$

and show that this implies $\mathrm{ran}(R) \subseteq \mathrm{ran}(S)$, that is,

$$\forall y\,(y \in \mathrm{ran}(R) \Rightarrow y \in \mathrm{ran}(S)). \tag{3.115}$$

For this purpose, we let y be arbitrary. and assume $y \in \mathrm{ran}(R)$, which implies by definition of a range that there exists an element, say $\bar{x}$, such that $(\bar{x}, y) \in R$ holds. This further implies $(\bar{x}, y) \in S$ with (3.114), so that $y \in \mathrm{ran}(S)$ holds (by definition of a range). As y is arbitrary, we therefore conclude that (3.115) holds, so that $\mathrm{ran}(R) \subseteq \mathrm{ran}(S)$ is true. Since R and S were also arbitrary, we finally conclude that the proposed universal sentence holds, as claimed. □

Exercise 3.18. Show that, if a binary relation R is included in a binary relation S, then the domain of R is included in the domain of S, that is,

$$\begin{aligned}&\forall R, S\,([R \text{ is a binary relation } \wedge\ S \text{ is a binary relation}]\\ &\quad \Rightarrow [R \subseteq S \Rightarrow \mathrm{dom}(R) \subseteq \mathrm{dom}(S)]).\end{aligned} \tag{3.116}$$

Corollary 3.35. *For any binary relation R and any set A it is true that the domain and the range of the restriction of R to A are included in, respectively, the domain and the range of R, i.e.*

$$\forall A\,(\mathrm{dom}(R \upharpoonright A) \subseteq \mathrm{dom}(R) \wedge \mathrm{ran}(R \upharpoonright A) \subseteq \mathrm{ran}(R)). \tag{3.117}$$

Proof. Letting R be an arbitrary binary relation and A an arbitrary set, we see in light of Corollary 3.23 that $R \upharpoonright A$ is a binary relation included in the binary relation R, so that $\mathrm{dom}(R \upharpoonright A) \subseteq \mathrm{dom}(R)$ and $\mathrm{ran}(R \upharpoonright A) \subseteq \mathrm{ran}(R)$ follow to be true with Exercise 3.18 and Proposition 3.34, respectively. Since R and A were arbitrary, we therefore conclude that the proposed sentence holds, as claimed. □

Proposition 3.36. *For any binary relation R it is true that, if the domain of R is empty, then the range of R is also empty, that is,*

$$\forall R\,(R \text{ is a binary relation } \Rightarrow [\mathrm{dom}(R) = \emptyset \Rightarrow \mathrm{ran}(R) = \emptyset]). \tag{3.118}$$

Proof. We let R be an arbitrary binary relation and prove the implication by contradiction, assuming $\mathrm{dom}(R) = \emptyset$ and $\mathrm{ran}(R) \neq \emptyset$ to be both true. As the latter assumption implies with (2.42) that there exists an element in $\mathrm{ran}(R)$, say $\bar{b}$. This further implies by definition of a range that there exists an element, say $\bar{a}$, such that $(\bar{a}, \bar{b}) \in R$ holds. This shows that the existential sentence $\exists b\,((\bar{a}, b) \in R)$ is true, which then implies $\bar{a} \in \mathrm{dom}(R)$ by definition of a range. With this finding, the previously made assumption $\mathrm{dom}(R) = \emptyset$ implies $\bar{a} \in \emptyset$, so that the existential sentence $\exists y\,(y \in \emptyset)$ holds. This however contradicts (2.41), so that the proof of the implication (3.118) is complete. As R was arbitrary, we therefore conclude that the proposition is true. □

Exercise 3.19. Prove for any binary relation R that the domain of R is empty iff the range of R is empty, that is,

$$\forall R\,(R \text{ is a binary relation } \Rightarrow [\mathrm{dom}(R) = \emptyset \Leftrightarrow \mathrm{ran}(R) = \emptyset]). \tag{3.119}$$

(Hint: Prove the second part ('$\Leftarrow$') of the equivalence according to the proof of the first part ('$\Rightarrow$') in (3.118), then apply Definition 1.5.)

Exercise 3.20. Verify the following sentences for any binary relation R.

$$R = \emptyset \;\Leftrightarrow\; \mathrm{dom}(R) = \emptyset, \tag{3.120}$$

$$R = \emptyset \;\Leftrightarrow\; \mathrm{ran}(R) = \emptyset. \tag{3.121}$$

(Hint: Regarding (3.120), apply Method 1.11 in connection with (2.42) and the Definitions 3.8 & 3.5. Regarding (3.121), apply (3.119).)

It is also possible to combine two given binary relations in the following sense.

Theorem 3.37. *The following sentences are true for any binary relations Q and R.*

a) There exists a unique set $R \circ Q$ which contains precisely every ordered pair in the Cartesian product of the domain of Q and the range of R such that its first coordinate coincides with the first coordinate of some ordered pair in Q and its second coordinate coincides with the second coordinate of some ordered pair in R, where the second coordinate of the ordered pair in Q and the first coordinate of the ordered pair in R are identical, that is,

$$\exists! R \circ Q \, \forall Y \, (Y \in R \circ Q \Leftrightarrow [Y \in \mathrm{dom}(Q) \times \mathrm{ran}(R) \\ \wedge \, \exists a, b, c \, ((a,b) \in Q \, \wedge \, (b,c) \in R \, \wedge \, (a,c) = Y)]). \tag{3.122}$$

b) The set $R \circ Q$ satisfies

$$R \circ Q \neq \emptyset \Leftrightarrow \exists a, b, c \, ((a,b) \in Q \, \wedge \, (b,c) \in R). \tag{3.123}$$

c) The set $R \circ Q$ satisfies also

$$\forall Y \, (Y \in R \circ Q \Leftrightarrow \exists a, b, c \, ((a,b) \in Q \, \wedge \, (b,c) \in R \, \wedge \, (a,c) = Y)). \tag{3.124}$$

Proof. Concerning a), letting Q and R be arbitrary binary relations, we we obtain with the Axiom of Specification

$$\exists R \circ Q \, \forall Y \, (Y \in R \circ Q \Leftrightarrow [Y \in \mathrm{dom}(Q) \times \mathrm{ran}(R) \\ \wedge \, \exists a, b, c \, ((a,b) \in Q \, \wedge \, (b,c) \in R \, \wedge \, (a,c) = Y)]).$$

The fact that $R \circ Q$ is unique follows by means of the Equality Criterion for sets in the usual way. Thus, the set $R \circ Q$ satisfies

$$\forall Y \, (Y \in R \circ Q \Leftrightarrow [Y \in \mathrm{dom}(Q) \times \mathrm{ran}(R) \\ \wedge \, \exists a, b, c \, ((a,b) \in Q \, \wedge \, (b,c) \in R \, \wedge \, (a,c) = Y)]). \tag{3.125}$$

Concerning b), we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $R \circ Q \neq \emptyset$ to hold, so that there evidently exists an element in $R \circ Q$, say $\bar{Y}$. Then, $\bar{Y} \in R \circ Q$ implies with (3.125) in particular that there are elements, say $\bar{a}$, $\bar{b}$ and $\bar{c}$, satisfying the (multiple) conjunction of $(\bar{a}, \bar{b}) \in Q$, $(\bar{b}, \bar{c}) \in R$ and $(\bar{a}, \bar{c}) = \bar{Y}$. The first two parts of this multiple conjunction show that the existential sentence in (3.123) holds, so that the proof of the first part of the equivalence (3.123) is complete.

To prove the second part ('$\Leftarrow$'), we now assume that Q and R are such that there exist elements, say $\bar{\bar{a}}$, $\bar{\bar{b}}$ and $\bar{\bar{c}}$, with $(\bar{\bar{a}}, \bar{\bar{b}}) \in Q$ and $(\bar{\bar{b}}, \bar{\bar{c}}) \in R$. Then, the ordered pair $\bar{\bar{Y}} = (\bar{\bar{a}}, \bar{\bar{c}})$ is uniquely specified, so that the existential sentence

$$\exists a, b, c\,((a,b) \in Q \;\wedge\; (b,c) \in R \;\wedge\; (a,c) = \bar{Y}) \tag{3.126}$$

holds. Furthermore, $(\bar{\bar{a}}, \bar{\bar{b}}) \in Q$ shows that there is an element b with $(\bar{\bar{a}}, b) \in Q$, so that $\bar{\bar{a}} \in \mathrm{dom}(Q)$ holds by definition of a domain. Moreover, $(\bar{\bar{b}}, \bar{\bar{c}}) \in R$ shows that there is an element b with $(b, \bar{\bar{c}}) \in R$, and therefore $\bar{\bar{c}} \in \mathrm{ran}(R)$ follows to be true by definition of a range. The conjunction of $\bar{\bar{a}} \in \mathrm{dom}(Q)$ and $\bar{\bar{c}} \in \mathrm{ran}(R)$ then implies

$$[(\bar{\bar{a}}, \bar{\bar{c}}) =] \quad \bar{Y} \in \mathrm{dom}(Q) \times \mathrm{ran}(R) \tag{3.127}$$

with the definition of the Cartesian product of two sets. Now, the conjunction of (3.127) and (3.126) further implies with (3.125) $\bar{Y} \in R \circ Q$, which shows that there exists an element in $R \circ Q$. Thus, the set $R \circ Q$ is clearly nonempty, and the proof of the equivalence (3.123) is therefore complete.

As Q and R were arbitrary, we may conclude that a) and b) are true universally. $\square$

Exercise 3.21. Prove Part c) of Theorem 3.37.

(Hint: Proceed similarly as in the proof of Theorem 3.7.)

Definition 3.10 (Composition). For any binary relations Q and R we call the set $R \circ Q$, characterized by

$$\forall Y\,(Y \in R \circ Q \Leftrightarrow \exists a, b, c\,((a,b) \in Q \;\wedge\; (b,c) \in R \;\wedge\; (a,c) = Y)),$$

the *composition* of R and Q.

Proposition 3.38. *The composition of a binary relations Q and a binary relation R is empty if Q or R is empty, that is,*

$$[Q = \emptyset \;\vee\; R = \emptyset] \;\Rightarrow\; R \circ Q = \emptyset. \tag{3.128}$$

Proof. We let Q and R be arbitrary binary relations, and we prove the implication by contraposition, assuming $R \circ Q \neq \emptyset$ to be true. According to (2.42), the composition then has some element, say $\bar{Y} \in R \circ Q$. Due to (3.124), there also exist constant, say $\bar{a}, \bar{b}, \bar{c}$, such that $(\bar{a}, \bar{b}) \in Q$ and $(\bar{b}, \bar{c}) \in R$. Consequently, the sets Q and R both are nonempty. The truth of the conjunction $Q \neq \emptyset \wedge R \neq \emptyset$ implies now the truth of the negation $\neg(Q = \emptyset \vee R = \emptyset)$ by virtue of De Morgan's Law for the disjunction. This finding completes the proof of the implication, and since Q and R were initially arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Corollary 3.39. *The composition of a binary relation R and the empty set yields the empty set, that is,*

$$R \circ \emptyset = \emptyset \;\wedge\; \emptyset \circ R = \emptyset. \tag{3.129}$$

Proof. Letting R be an arbitrary binary relation, the evident truth of $\emptyset = \emptyset$ implies the truth of the disjunctions $\emptyset = \emptyset \vee R = \emptyset$ and $R = \emptyset \vee \emptyset = \emptyset$, which in turn imply $R \circ \emptyset = \emptyset$ and $\emptyset \circ R = \emptyset$ with (3.128). As R was arbitrary, we therefore conclude that the corollary holds. □

Proposition 3.40. *For any binary relations Q and R such that the range of Q is included in the domain of R, it is true that the domain of the composition $R \circ Q$ is identical with the domain of Q, that is,*

$$\begin{aligned}&\forall Q, R\,([Q, R \text{ are binary relations} \wedge \operatorname{ran}(Q) \subseteq \operatorname{dom}(R)]\\ &\quad \Rightarrow \operatorname{dom}(R \circ Q) = \operatorname{dom}(Q)).\end{aligned} \tag{3.130}$$

Proof. We let Q and R be arbitrary binary relations with $\operatorname{ran}(Q) \subseteq \operatorname{dom}(R)$, so that

$$\forall b\,(b \in \operatorname{ran}(Q) \Rightarrow b \in \operatorname{dom}(R)). \tag{3.131}$$

holds by definition of a subset. To prove $\operatorname{dom}(R \circ Q) = \operatorname{dom}(Q)$, we verify

$$\forall a\,(a \in \operatorname{dom}(R \circ Q) \Leftrightarrow a \in \operatorname{dom}(Q)), \tag{3.132}$$

letting $\bar{a}$ be arbitrary. To show that the first implication ($\Rightarrow$) holds, we assume $\bar{a} \in \operatorname{dom}(R \circ Q)$. Then, by definition of a domain, there exists an element, say $\bar{c}$, such that $(\bar{a}, \bar{c}) \in R \circ Q$ holds. This implies with the definition of a composition in particular $(\bar{a}, \bar{c}) \in \operatorname{dom}(Q) \times \operatorname{ran}(R)$, which further implies $\bar{a} \in \operatorname{dom}(Q)$ by definition of the Cartesian product of two sets, as desired.

We now show that the second implication ($\Leftarrow$) also holds, which we do directly by assuming $\bar{a} \in \operatorname{dom}(Q)$ to be true. Then, by definition of a domain, there exists an element, say $\bar{b}$, such that $(\bar{a}, \bar{b}) \in Q$ is true. This in turn implies $\bar{b} \in \operatorname{ran}(Q)$ by definition of a range and then $\bar{b} \in \operatorname{dom}(R)$ with (3.131). By definition of a domain, there exists an element, say $\bar{c}$, such that $(\bar{b}, \bar{c}) \in R$ holds. Let us now define the ordered pair $Y = (\bar{a}, \bar{c})$ Then, $(\bar{a}, \bar{b}) \in Q$, $(\bar{b}, \bar{c}) \in R$ and $(\bar{a}, \bar{c}) = Y$ show that there exist a, b, c such that

$(a,b) \in Q$, $(b,c) \in R$ and $(a,c) = Y$ hold. This existential sentence implies $Y \in R \circ Q$ with (3.124), and therefore $(\bar{a}, \bar{c}) \in R \circ Q$. Applying now the definition of a domain, we obtain the desired $\bar{a} \in \mathrm{dom}(R \circ Q)$.

Thus, the proof of the equivalence in (3.132) is complete. Since $\bar{a}$ is arbitrary, we therefore conclude that (3.132) holds, so that the sets $\mathrm{dom}(R \circ Q)$ and $\mathrm{dom}(Q)$ follow to be identical with the Equality Criterion for sets. As Q and R were also arbitrary, we further conclude that the proposition (3.130) is true. □

Exercise 3.22. Show for any binary relations Q and R such that the range of Q is included in the domain of R that the range of the composition $R \circ Q$ is included in the range of R, that is,

$$\begin{aligned} &\forall Q, R\,([Q, R \text{ are binary relations} \wedge \mathrm{ran}(Q) \subseteq \mathrm{dom}(R)] \\ &\quad \Rightarrow \mathrm{ran}(R \circ Q) \subseteq \mathrm{ran}(R)). \end{aligned} \tag{3.133}$$

(Hint: Proceed in analogy to the proof of the first part of the equivalence in (3.132), using the definition of a range instead of the definition of a domain.)

We also obtain a new binary relation by interchanging the coordinates of the ordered pairs in a given binary relation.

Theorem 3.41. *The following sentences hold for any binary relation R.*

a) There exists a unique set R^{-1} such that an element Y is in R^{-1} iff Y is in the Cartesian product of the range of R and the domain of R, and moreover if there is an ordered pair in R whose first coordinate is the second coordinate of Y and whose second coordinate is the first coordinate of Y, that is,

$$\begin{aligned} &\exists! R^{-1}\, \forall Y\, (Y \in R^{-1} \\ &\quad \Leftrightarrow [Y \in \mathrm{ran}(R) \times \mathrm{dom}(R) \wedge \exists a, b\,((a,b) \in R \wedge (b,a) = Y])). \end{aligned} \tag{3.134}$$

b) The set R^{-1} is nonempty iff R is nonempty, that is,

$$R^{-1} \neq \emptyset \Leftrightarrow R \neq \emptyset. \tag{3.135}$$

c) The set R^{-1} satisfies also

$$\forall Y\, (Y \in R^{-1} \Leftrightarrow \exists a, b\,((a,b) \in R \wedge (b,a) = Y)). \tag{3.136}$$

Proof. We let R be an arbitrary binary relation. Concerning a), we may use the Axiom of Specification to obtain the true existential sentence

$$\exists R^{-1}\,\forall Y\,(Y \in R^{-1} \\ \Leftrightarrow [Y \in \mathrm{ran}(R) \times \mathrm{dom}(R) \,\wedge\, \exists a,b\,((a,b) \in R \,\wedge\, (b,a) = Y])),$$

and we may apply then the Equality Criterion for sets to establish the unique existence of R^{-1} in the usual way. This set thusly satisfies

$$\forall Y\,(Y \in R^{-1} \Leftrightarrow [Y \in \mathrm{ran}(R) \times \mathrm{dom}(R) \,\wedge\, \exists a,b\,((a,b) \in R \,\wedge\, (b,a) = Y])). \tag{3.137}$$

Concerning b), we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $R^{-1} \neq \emptyset$ holds. Clearly, there exists then an element in R^{-1}, say $\bar{Y}$. Consequently, $\bar{Y} \in R^{-1}$ implies with (3.137) in particular that there are elements, say $\bar{a}$ and $\bar{b}$, such that $(\bar{a},\bar{b}) \in R$ and $(\bar{b},\bar{a}) = \bar{Y}$ hold. Here, $(\bar{a},\bar{b}) \in R$ clearly shows that there exists an element in R, so that R is nonempty. Thus, the first part of the equivalence in (3.135) is true.

To prove the second part, we now assume R to be nonempty, so that there is an element in R, say $\bar{Z}$. This implies with the definition of a binary relation that there exist elements, say $\bar{\bar{a}}$ and $\bar{\bar{b}}$, with $\bar{Z} = (\bar{\bar{a}},\bar{\bar{b}})$. Then, $\bar{Z} \in R$ yields $(\bar{\bar{a}},\bar{\bar{b}}) \in R$. Thus, there is, on the one hand, an element b with $(\bar{\bar{a}},b) \in R)$, so that $\bar{\bar{a}} \in \mathrm{dom}(R)$ holds by definition of a domain. On the other hand, we see that there is an element a such that $(a,\bar{\bar{b}}) \in R$ holds, which implies $\bar{\bar{b}} \in \mathrm{ran}(R)$ by definition of a range. The previous two findings give with (3.28)

$$(\bar{\bar{b}},\bar{\bar{a}}) \in \mathrm{ran}(R) \times \mathrm{dom}(R). \tag{3.138}$$

Denoting $Y = (\bar{\bar{b}},\bar{\bar{a}})$, we thus showed that $Y \in \mathrm{ran}(R) \times \mathrm{dom}(R)$ holds and that there are elements a,b with $(a,b) \in R$ as well as $(b,a) = Y$. Consequently, Y is an element of R^{-1} because of (3.137), and therefore the set R^{-1} is nonempty. Thus, the proof of b) is complete.

Concerning c), we let Y be arbitrary, and we prove the first part ('$\Rightarrow$') of the equivalence in (3.136) directly, assuming $Y \in R^{-1}$ to be true. Then, this gives in particular the existential sentence in (3.136) to be proven. To prove the second part ('$\Leftarrow$') directly, we assume the truth of the existential sentence

$$\exists a,b\,((a,b) \in R \,\wedge\, (b,a) = Y), \tag{3.139}$$

i.e., that there exist elements, say $\bar{a}$ and $\bar{b}$ such that $(\bar{a},\bar{b}) \in R$ and $(\bar{b},\bar{a}) = Y$ hold. Here, $(\bar{a},\bar{b}) \in R$ implies on the one hand $\bar{a} \in \mathrm{dom}(R)$ by definition of a domain, and on the other hand $\bar{b} \in \mathrm{ran}(R)$ by definition of a range. Consequently,

$$[(\bar{b},\bar{a}) =] \quad Y \in \mathrm{ran}(R) \times \mathrm{dom}(R)$$

follows to be true with (3.28). Together with the assumed existential sentence, this further implies with (3.137) $Y \in R^{-1}$, as desired. This completes the proof of the equivalence, and since Y is arbitrary, we may therefore conclude that c) holds, too.

Finally, as R was arbitrary, the theorem follows to be true. □

Definition 3.11 (Inverse of a binary relation). For any binary relation R we call the set R^{-1} containing precisely any ordered pair whose first coordinate is the second coordinate and whose second coordinate is the first coordinate of some ordered pair in R, in the sense that

$$\forall Y\,(Y \in R^{-1} \Leftrightarrow \exists a, b\,((a,b) \in R \wedge (b,a) = Y)),$$

the *inverse* of R. We symbolize this set also by

$$\{(b,a) : (a,b) \in R\}. \tag{3.140}$$

Corollary 3.42. *For any binary relation R it is true that the inverse of R is a subset of the Cartesian product of the range and the domain of R, i.e.*

$$R^{-1} \subseteq \mathrm{ran}(R) \times \mathrm{dom}(R). \tag{3.141}$$

Proof. Letting R be an arbitrary binary relation, we see in light of (3.137) that $Y \in R^{-1}$ implies in particular $Y \in \mathrm{ran}(R) \times \mathrm{dom}(R)$ for any Y, so that (3.141) holds by definition of a subset. As R is arbitrary, this inclusion is then true for any R. □

Proposition 3.43. *For any binary relation R, it is true that the ordered pair formed by some b and some a is element of the inverse of R iff the ordered pair formed by a and b is in R, i.e.*

$$\forall a, b\,((b,a) \in R^{-1} \Leftrightarrow (a,b) \in R). \tag{3.142}$$

Proof. We let R be an arbitrary set, assume that R is a binary relation, and let $\bar{a}$ as well as $\bar{b}$ be arbitrary. To prove the first part ('⇒') of the equivalence, we assume $(\bar{b}, \bar{a}) \in R^{-1}$ to be true, which implies with the definition of the inverse of a binary relation that there exist elements, say $\bar{\bar{a}}$ and $\bar{\bar{b}}$, such that $(\bar{\bar{a}}, \bar{\bar{b}}) \in R$ and $(\bar{\bar{b}}, \bar{\bar{a}}) = (\bar{b}, \bar{a})$ are true. This equation implies with the Equality Criterion for ordered pairs that the equations $\bar{\bar{b}} = \bar{b}$ and $\bar{\bar{a}} = \bar{a}$ hold, so that the previously established $(\bar{\bar{a}}, \bar{\bar{b}}) \in R$ yields $(\bar{a}, \bar{b}) \in R$ via substitution. Thus, the first part of the equivalence in (3.142) is true. To prove the second part ('⇐'), we now assume $(\bar{a}, \bar{b}) \in R$ to be true. Since the ordered pair $(\bar{b}, \bar{a})$ is also specified by $\bar{a}$ and $\bar{b}$, we thus see that there are elements a and b such that the conjunction $(a,b) \in R \wedge (b,a) = (\bar{b}, \bar{a})$ holds.

This existential sentence then implies (with the definition of the inverse of a binary relation) that $(\bar{b}, \bar{a}) \in R^{-1}$ is true, which completes the proof of the equivalence. Since $\bar{a}$ and $\bar{b}$ were arbitrary, we may therefore conclude that the universal sentence (3.142) holds. As R was initially also arbitrary, we may then infer from this the truth of the proposed sentence. □

Theorem 3.44 (Characterization of the domain of the inverse of a binary relation). *The domain of the inverse of a binary relation R is identical with the domain of R, that is,*

$$\forall R\,(R \text{ is a binary relation } \Rightarrow \operatorname{dom}(R^{-1}) = \operatorname{ran}(R)). \tag{3.143}$$

Proof. We let R be arbitrary and assume that R is a binary relation. Now, we apply the Equality Criterion for sets to prove the proposed equation, by verifying equivalently

$$\forall b\,(b \in \operatorname{dom}(R^{-1}) \Leftrightarrow b \in \operatorname{ran}(R)). \tag{3.144}$$

We let $\bar{b}$ be arbitrary and assume first $\bar{b} \in \operatorname{dom}(R^{-1})$ to be true. By definition of a domain, there then exists an element, say $\bar{a}$, such that $(\bar{b}, \bar{a}) \in R^{-1}$ holds. This implies with Proposition 3.43 the truth of $(\bar{a}, \bar{b}) \in R$, which shows that there is an element a satisfying $(a, \bar{b}) \in R$, so that $\bar{b} \in \operatorname{ran}(R)$ follows to be true by definition of a range. Conversely, we now assume $\bar{b} \in \operatorname{ran}(R)$ to be true, so that there exists (by definition of a range) an element, say $\bar{a}$, with $(\bar{a}, \bar{b}) \in R$. Then, Proposition 3.43 gives $(\bar{b}, \bar{a}) \in R^{-1}$, which shows that there is an element a which satisfies $(\bar{b}, a) \in R^{-1}$, so that $\bar{b} \in \operatorname{dom}(R^{-1})$ holds (by definition of a domain). Thus, the equivalence in (3.144) holds, and since $\bar{b}$ is arbitrary, we may therefore conclude that the (3.144) is true. This universal sentence in turn implies the equation $\operatorname{dom}(R^{-1}) = \operatorname{ran}(R)$ (with the Equality Criterion for sets), and as R was arbitrary, we may then further conclude that the proposed universal sentence (3.143) is true. □

3.3. Ordered Sets

3.3.1. Basic characteristics of partially, totally and linearly ordered sets

In this section we will investigate binary relations which satisfy certain combinations of the definite properties listed in the subsequent definition.

Definition 3.12. For any set X we say that a binary relation R on X is

(1) *reflexive* iff
$$\forall a\,(a \in X \Rightarrow a\,R\,a). \tag{3.145}$$

(2) *irreflexive* iff
$$\forall a\,(a \in X \Rightarrow \neg a\,R\,a), \tag{3.146}$$

(3) *symmetric* iff
$$\forall a, b\,(a, b \in X \Rightarrow [a\,R\,b \Rightarrow b\,R\,a]). \tag{3.147}$$

(4) *antisymmetric* iff
$$\forall a, b\,(a, b \in X \Rightarrow [(a\,R\,b \,\wedge\, b\,R\,a) \Rightarrow a = b]). \tag{3.148}$$

(5) *transitive* iff
$$\forall a, b, c\,(a, b, c \in X \Rightarrow [(a\,R\,b \,\wedge\, b\,R\,c) \Rightarrow a\,R\,c]). \tag{3.149}$$

(6) *total* iff
$$\forall a, b\,(a, b \in X \Rightarrow [a\,R\,b \,\vee\, b\,R\,a]). \tag{3.150}$$

(7) *connex* iff
$$\forall a, b\,(a, b \in X \Rightarrow [a\,R\,b \,\vee\, b\,R\,a \,\vee\, a = b]), \tag{3.151}$$

(8) *comparable* or *trichotomous* iff
$$\begin{aligned}\forall a, b\,(a, b \in X \Rightarrow [&(a\,R\,b \,\vee\, b\,R\,a \,\vee\, a = b) \\ &\wedge \neg(a\,R\,b \,\wedge\, b\,R\,a) \,\wedge\, \neg(a\,R\,b \,\wedge\, a = b) \,\wedge\, \neg(b\,R\,a \,\wedge\, a = b)])\end{aligned} \tag{3.152}$$

Corollary 3.45. *The empty binary relation $R = \emptyset$ on $X = \emptyset$ is reflexive, irreflexive, symmetric, antisymmetric, transitive, total, connex, comparable.*

Proof. In view of Exercise 3.8, any binary relation on $X = \emptyset$ is itself the empty set. Furthermore, letting a, b and c be arbitrary, we see that the antecedents $a \in X$ regarding Property (1) and (2), the antecedents $a, b \in X$ with respect to the Properties (3), (4), (6), (7) and (8), and the antecedent $a, b, c \in X$ concerning Property (5) are all false by definition of the empty set. Therefore, the corresponding implications are all true, so that the Properties (1) – (8) follow to be true for $R = \emptyset$ on $X = \emptyset$. $\square$

Corollary 3.46. *The empty binary relation $R = \emptyset$ on a nonempty set X is irreflexive (and not reflexive), symmetric, antisymmetric, transitive, and not total.*

Proof. We let X be an arbitrary nonempty set, $R = \emptyset$ be the empty binary relation on X, and we let in the following a, b and c be arbitrary elements of X. Since R is empty, we have that $(a, a) \in R$, $(a, b) \in R$, $(b, a) \in R$ and $(b, c) \in R$ are all false; thus, $a \, R \, a$, $a \, R \, b$, $b \, R \, a$ and $b \, R \, c$ are also false.

Since $a \in X$ implies the false $a \, R \, a$, we see that R is not reflexive according to (3.145). Then, $\neg a \, R \, a$ is true, so that R is indeed irreflexive according to (3.146). Next, since $a \, R \, b$ is false, the implication in (3.147) based on this antecedent is true, and therefore R is symmetric. Moreover, as the conjunction of $a \, R \, b$ and $b \, R \, a$ is false, the implication in (3.148) based on this false antecedent is true, so that R follows to be also antisymmetric. Similarly, because the conjunction of $a \, R \, b$ and $b \, R \, c$ is false, the implication in (3.149) with this false antecedent holds, and R follows therefore to be transitive. Furthermore, the previously mentioned fact that $a \, R \, b$ and $b \, R \, a$ are both false implies that the disjunction $a \, R \, b \vee b \, R \, a$ in (3.150) is also false, so that R is not total. $\square$

Exercise 3.23. Show that any binary relation R on any singleton $\{x\}$ is connex.

(Hint: Establish the disjunction in (3.151) by using (2.169).)

Exercise 3.24. Show for any x that the empty binary relation $R = \emptyset$ on the singleton $\{x\}$ is comparable.

(Hint: Use Exercise 3.23.)

Proposition 3.47. *For any x it is true that the singleton $R = \{(x, x)\}$ is a reflexive, symmetric, antisymmetric, transitive, total and connex binary relation on the singleton $X = \{x\}$.*

Proof. We let x be arbitrary and observe in light of Proposition 3.21 and the definition of a singleton that $R = \{(x, x)\}$ is a binary relation $\{x, x\} =$

$\{x\}$. Next, we verify the claimed properties of R and let for this purpose $a, b, c \in \{x\}$ be arbitrary, which assumption implies the equations

$$a = x,\ b = x,\ c = x \tag{3.153}$$

with (2.169). The latter argument also gives $(x, x) \in R\ [= \{(x, x)\}]$, so that substitutions based on the equations (3.153) yield

$$(a, a), (a, b), (a, c), (b, a), (b, c) \in R,$$

which we may also write as

$$a\,R\,a,\ a\,R\,b,\ a\,R\,c,\ b\,R\,a,\ b\,R\,c. \tag{3.154}$$

Here, the truth of $a\,R\,a$ shows that $R = \{(x, x)\}$ satisfies the implication in (3.145), and therefore we may conclude that R is reflexive (since a is arbitrary). In addition, we notice that the equations (3.153) imply

$$a = b. \tag{3.155}$$

Let us now observe that the truth of (3.154) and of (3.155) immediately causes the implications

$$\begin{aligned} a\,R\,b &\Rightarrow b\,R\,a, \\ (a\,R\,b \wedge b\,R\,a) &\Rightarrow a = b, \\ (a\,R\,b \wedge b\,R\,c) &\Rightarrow a\,R\,c, \end{aligned}$$

in (3.147) – (3.149) to be true themselves; since a, b and c are arbitrary, we may therefore conclude that R is symmetric, antisymmetric, and transitive. Clearly, the truth of (3.154) causes also the truth of the disjunction $a\,R\,b \vee b\,R\,a$ in (3.150), from which we may infer that R is total (since a and b are arbitrary). In view of Exercise 3.23, R is also connex. As x was initially arbitrary, we may finally conclude that the proposed universal sentence holds. □

Proposition 3.48. *For any x and y it is true that the singleton $R = \{(x, y)\}$ is a transitive binary relation on the pair $\{x, y\}$.*

Proof. Letting x and y be arbitrary, we have due to Proposition 3.21 that $R = \{(x, y)\}$ is a binary relation on $\{x, y\}$. To prove that R is transitive, we let a, b and c be arbitrary, assume $a, b, c \in \{x, y\}$ to be true, and assume furthermore that $a\,R\,b$ and $b\,R\,c$ are both true. Since we may write the latter assumptions also as $(a, b) \in \{(x, y)\}$ and $(b, c) \in \{(x, y)\}$, we obtain the equations $(a, b) = (x, y)$ and $(b, c) = (x, y)$ with (2.169). Then, combining these equations clearly gives $(a, b) = (b, c)$ and therefore $b = c$ with the Equality Criterion for ordered pairs. With this equation, the assumed sentence $a\,R\,b$ yields $a\,R\,c$ via substitution. Since a, b and c are arbitrary, we may therefore conclude that R satisfies (3.149), so that $R = \{(x, y)\}$ is a transitive binary relation on the pair $\{x, y\}$. As x and y were also arbitrary, we may now further conclude that the proposition is true. $\square$

Theorem 3.49 (Characterization of comparability). *For any set X and any binary relation R on X it is true that R is comparable iff precisely one of the three sentences $a\,R\,b$, $b\,R\,a$ and $a = b$ is true for any elements a and b in X, i.e. iff*

$$\begin{aligned}\forall a, b\,(a, b \in X \Rightarrow [(a\,R\,b \,\wedge\, [\neg b\,R\,a] \,\wedge\, a \neq b) \\ \vee ([\neg a\,R\,b] \,\wedge\, b\,R\,a \,\wedge\, a \neq b) \\ \vee ([\neg a\,R\,b] \,\wedge\, [\neg b\,R\,a] \,\wedge\, a = b)]).\end{aligned} \tag{3.156}$$

Proof. Let us take arbitrary sets X and R, and let us assume that R is a binary relation on X. To prove the first part ('$\Rightarrow$') of the stated equivalence, we further assume that R is comparable, so that R satisfies the universal sentence (3.152). To show that this implies (3.156), we let a and b be arbitrary, and we assume $a, b \in X$ to hold. This assumption implies with (3.152) on the one hand the truth in particular of

$$\neg(a\,R\,b \,\wedge\, b\,R\,a), \tag{3.157}$$
$$\neg(a\,R\,b \,\wedge\, a = b), \tag{3.158}$$
$$\neg(b\,R\,a \,\wedge\, a = b), \tag{3.159}$$

which negations in turn imply with De Morgan's Law for sentences (1.51)

$$\neg a\,R\,b \,\vee\, \neg b\,R\,a, \tag{3.160}$$
$$\neg a\,R\,b \,\vee\, a \neq b, \tag{3.161}$$
$$\neg b\,R\,a \,\vee\, a \neq b. \tag{3.162}$$

On the other hand, we obtain from (3.152) the true disjunction

$$a\,R\,b \,\vee\, b\,R\,a \,\vee\, a = b. \tag{3.163}$$

In case the first part $a\,R\,b$ is true, we see immediately that the first part of the multiple conjunction

$$a\,R\,b \,\wedge\, [\neg b\,R\,a] \,\wedge\, a \neq b \tag{3.164}$$

in (3.156) holds. Furthermore, since the case assumption implies that $\neg a\,R\,b$ is false, it follows from the truth of the disjunctions (3.160) and (3.161) that their respective second parts $\neg b\,R\,a$ and $a \neq b$ are true, so that the second and third part of the multiple conjunction (3.164) also hold. Then, the truth of (3.164) clearly implies the truth of the multiple disjunction in (3.156) to be proven.

In case the second part $b\,R\,a$ of the disjunction (3.163) is true, this means that the second part of the multiple conjunction

$$[\neg a\,R\,b] \wedge b\,R\,a \wedge a \neq b \tag{3.165}$$

holds. Since $\neg b\,R\,a$ is now false, we also obtain from the true disjunctions (3.160) and (3.162) the true negations $\neg a\,R\,b$ and $a \neq b$, respectively, so that the multiple conjunction (3.165) holds. Then, the multiple disjunction in (3.156) is again true.

In the final case that the third part $a = b$ in (3.163) is true, we now see that the third part of the conjunction

$$[\neg a\,R\,b] \wedge [\neg b\,R\,a] \wedge a = b \tag{3.166}$$

holds. Moreover, the falsehood of $a \neq b$ yields in view of the true disjunctions (3.161) and (3.162) the true negations $\neg a\,R\,b$ and $\neg b\,R\,a$. Thus, (3.166) holds, so that the multiple disjunction in (3.156) is true also in this case. Since we showed that the consequent of the implication in (3.156) holds in any case, and since a and b are arbitrary, we may infer from this finding the truth of the universal sentence (3.156), completing the proof of the first part of the proposed equivalence.

To prove the second part ('$\Leftarrow$'), we now assume (3.156) to be true and show that R satisfies (3.152). Letting a and b be arbitrary and assuming $a, b \in X$ to be true, it now follows with the preceding assumption that the multiple disjunction

$$\begin{aligned} &(a\,R\,b \wedge [\neg b\,R\,a] \wedge a \neq b) \\ \vee\, &([\neg a\,R\,b] \wedge b\,R\,a \wedge a \neq b) \\ \vee\, &([\neg a\,R\,b] \wedge [\neg b\,R\,a] \wedge a = b) \end{aligned} \tag{3.167}$$

is true. If its first part (3.167) holds, then $a\,R\,b$ is in particular true, and therefore the multiple disjunction (3.163) is also satisfied by R. Moreover, (3.167) implies in particular $\neg b\,R\,a$ as well as $a \neq b$, so that the disjunctions (3.160) – (3.162) are clearly all satisfied by R. These further imply (3.157) – (3.159) with De Morgan's Law for sentences (1.51); together with the previously established (3.163), this shows that the multiple conjunction in (3.152) is thus satisfied by R in the first case.

Next, if the second part of the disjunction (3.167) holds, then $b\,R\,a$ is now in particular true, with the consequence that the multiple disjunction

(3.163) is again satisfied by R. Since we also obtain the true negations $\neg a\,R\,b$ and $a \neq b$, the disjunctions (3.160) – (3.162) are evidently all true, as in the first case. Consequently, they give again the true negations (3.157) – (3.159), besides the true (3.163). Thus, the multiple conjunction in (3.152) is satisfied also in the second case.

Finally, if the third part in (3.167) holds, then we have in particular the true equation $a = b$, and the disjunction (3.163) holds then as well. In addition, (3.167) yields the true negations $\neg a\,R\,b$ and $\neg b\,R\,a$, and we see once again that the disjunctions (3.160) – (3.162) are true. In analogy to the first and the second case, we may therefore establish the truth of the multiple conjunction in (3.152), which thus holds in any case.

Because a and b are arbitrary, we may therefore conclude that R satisfies (3.152), so that R is comparable by definition. Thus, the proof of the proposed equivalence is complete, and since X and R were initially arbitrary sets, we may now further conclude that the stated theorem is true. □

Proposition 3.50. *For any x and y satisfying $x \neq y$ it is true that the singleton $R = \{(x, y)\}$ is a comparable binary relation on $\{x, y\}$.*

Proof. We take arbitrary x and y such that $x \neq y$ holds and recall from Proposition 3.50 that $R = \{(x, y)\}$ is a (transitive) binary relation on $\{x, y\}$. It will be useful for us to establish first the following four sentences:

$$x\,R\,y, \tag{3.168}$$

$$\neg x\,R\,x, \tag{3.169}$$

$$\neg y\,R\,y, \tag{3.170}$$

$$\neg y\,R\,x. \tag{3.171}$$

Because $(x, y) \in \{(x, y)\}$ $[= R]$ holds according to (2.153), we obtain $(x, y) \in R$, which we may also write as (3.168). We may prove the remaining three sentences by contradiction. Assuming $x\,R\,x$ to be true, we may write this as $(x, x) \in \{(x, y)\}$ $[= R]$, which yields $(x, x) = (x, y)$ with (2.169) and therefore especially $x = y$ with the Equality Criterion for ordered pairs, in contradiction to the assumption $x \neq y$. Similarly, the assumption $y\,R\,y$ may be stated as $(y, y) \in \{(x, y)\}$ $[= R]$, which gives $(y, y) = (x, y)$ (again with (2.169)) and consequently in particular $y = x$ (using again the Equality Criterion for ordered pairs), so that we obtain the same contradiction as before. Finally, the assumption $y\,R\,x$ means $(y, x) \in \{(x, y)\}$ $[= R]$, which implies $(y, x) = (x, y)$ and then $x = y$ (using the same arguments as before), once again in contradiction to the true negation $x \neq y$.

We now apply the Characterization of comparability, letting a and b be arbitrary and assuming $a, b \in \{x, y\}$ to be true. Here, $a \in \{x, y\}$ implies by definition of a pair the true disjunction $a = x \vee a = y$, which we use to prove the multiple disjunction in (3.156) for $R = \{(x, y)\}$ by cases. In the first case of $a = x$, we observe that $b \in \{x, y\}$ yields the the true disjunction $b = x \vee b = y$, which we employ for a proof of the desired sentence by cases within the current first case. On the one hand, if $b = x$ holds (besides the current case assumption $a = x$), we obtain via substitution $a = b$ and from (3.169) the $\neg a\, R\, b$ as well as $\neg b\, R\, a$, so that the multiple conjunction

$$\neg a\, R\, b \wedge \neg b\, R\, a \wedge a = b \tag{3.172}$$

holds. Then, the multiple disjunction in (3.156) is evidently also true. On the other hand, if $b = y$ holds (alongside $a = x$), then the initial assumption $x \neq y$ yields $a \neq b$ via substitution, the sentence (3.168) gives $a\, R\, b$, and (3.171) implies $\neg b\, R\, a$. Thus, we now have the true multiple conjunction

$$a\, R\, b \wedge \neg b\, R\, a \wedge a \neq b,$$

so that the multiple disjunction in (3.156) follows again to be true. We now consider the second case $a = y$ and then again the two (sub)cases $b = x$ and $b = y$. On the one hand, if $b = x$ is true, the assumed $x \neq y$ gives $a \neq b$, and the sentences (3.168) and (3.171) imply $b\, R\, a$ and $\neg a\, R\, b$, respectively, so that we obtain the truth of

$$\neg a\, R\, b \wedge b\, R\, a \wedge a \neq b,$$

and therefore the truth of the desired multiple disjunction. On the other hand, if $b = y$ is true, it follows with the current case assumption $a = y$ that $a = b$ holds; furthermore, (3.170) gives $\neg a\, R\, b$ as well as $b\, R\, a$, so that (3.172) is true again. Thus, $R = \{(x, y)\}$ satisfies the multiple disjunction in (3.156) in any case, and since a and b were arbitrary, we may therefore conclude that this binary relation is indeed comparable. □

It will be also useful for to know the following link between comparability, irreflexivity and connexity.

Lemma 3.51. *For any set X and any transitive binary relation R on X, it is true that R is irreflexive and connex iff R is comparable.*

Proof. We let X be an arbitrary set and R an arbitrary transitive binary relation on X. We now prove the first part ('⇒') of the stated equivalence by contradiction, assuming that R is irreflexive and connex, i.e.

$$\forall a\, (a \in X \Rightarrow \neg a\, R\, a) \wedge \forall a, b\, (a, b \in X \Rightarrow [a\, R\, b \vee b\, R\, a \vee a = b]) \tag{3.173}$$

and assuming that R is not comparable, i.e.

$$\neg\forall a,b\,(a,b\in X\Rightarrow[(a\,R\,b\,\vee\,b\,R\,a\,\vee\,a=b)\\ \wedge\,\neg(a\,R\,b\,\wedge\,b\,R\,a)\,\wedge\,\neg(a\,R\,b\,\wedge\,a=b)\,\wedge\,\neg(b\,R\,a\,\wedge\,a=b)]). \tag{3.174}$$

Here, we may write the latter negation equivalently as

$$\exists a,b\,(a,b\in X\wedge\neg[(a\,R\,b\,\vee\,b\,R\,\vee\,a=b)\\ \wedge\,\neg(a\,R\,b\,\wedge\,b\,R\,a)\,\wedge\,\neg(a\,R\,b\,\wedge\,a=b)\,\wedge\,\neg(b\,R\,a\,\wedge\,a=b)])$$

by applying the Quantifier Negation Law (1.53) and (1.82) in connection with the Double Negation Law. Thus, there are elements in X, say $\bar{a}$ and $\bar{b}$, with

$$\neg[(\bar{a}\,R\,\bar{b}\,\vee\,\bar{b}\,R\,\bar{a}\,\vee\,\bar{a}=\bar{b})\\ \wedge\,\neg(\bar{a}\,R\,\bar{b}\,\wedge\,\bar{b}\,R\,\bar{a})\,\wedge\,\neg(\bar{a}\,R\,\bar{b}\,\wedge\,\bar{a}=\bar{b})\,\wedge\,\neg(\bar{b}\,R\,\bar{a}\,\wedge\,\bar{a}=\bar{b})]$$

Let us now apply De Morgan's Law for the conjunction successively to obtain first

$$\neg(\bar{a}\,R\,\bar{b}\,\vee\,\bar{b}\,R\,\bar{a}\,\vee\,\bar{a}=\bar{b})\\ \vee\,\neg[\neg(\bar{a}\,R\,\bar{b}\,\wedge\,\bar{b}\,R\,\bar{a})\,\wedge\,\neg(\bar{a}\,R\,\bar{b}\,\wedge\,\bar{a}=\bar{b})\,\wedge\,\neg(\bar{b}\,R\,\bar{a}\,\wedge\,\bar{a}=\bar{b})],$$

then in connection with the Double Negation Law and the Associative Law for the conjunction as well as for the disjunction

$$\neg(\bar{a}\,R\,\bar{b}\,\vee\,\bar{b}\,R\,\bar{a}\,\vee\,\bar{a}=\bar{b})\,\vee\,(\bar{a}\,R\,\bar{b}\,\wedge\,\bar{b}\,R\,\bar{a})\\ \vee\,\neg[\neg(\bar{a}\,R\,\bar{b}\,\wedge\,\bar{a}=\bar{b})\,\wedge\,\neg(\bar{b}\,R\,\bar{a}\,\wedge\,\bar{a}=\bar{b})],$$

and moreover

$$\neg(\bar{a}\,R\,\bar{b}\vee\bar{b}\,R\,\bar{a}\vee\bar{a}=\bar{b})\vee(\bar{a}\,R\,\bar{b}\wedge\bar{b}\,R\,\bar{a})\vee(\bar{a}\,R\,\bar{b}\wedge\bar{a}=\bar{b})\vee(\bar{b}\,R\,\bar{a}\wedge\bar{a}=\bar{b}). \tag{3.175}$$

If the first part of this multiple disjunction is true, then we obtain a contradiction since $\bar{a},\bar{b}\in X$ implies with the second part of the assumed conjunction (3.173), i.e. with the assumed connexity of R, the truth of $\bar{a}\,R\,\bar{b}\,\vee\,\bar{b}\,R\,\bar{a}\,\vee\,\bar{a}=\bar{b}$. Next, if the second part $\bar{a}\,R\,\bar{b}\,\wedge\,\bar{b}\,R\,\bar{a}$ of the multiple disjunction (3.175) holds, then this yields $\bar{a}\,R\,\bar{a}$ with the initially assumed transitivity (3.149) of R. Also, if the third part $\bar{a}\,R\,\bar{b}\,\wedge\,\bar{a}=\bar{b}$ or the fourth part $\bar{b}\,R\,\bar{a}\,\wedge\,\bar{a}=\bar{b}$ is true, then the equation $\bar{a}=\bar{b}$ holds in particular, so that substitution in the true $\bar{a}\,R\,\bar{b}$ and $\bar{b}\,R\,\bar{a}$ yields $\bar{a}\,R\,\bar{a}$ in any case. Since $\bar{a}\in X$ implies also $\neg\bar{a}\,R\,\bar{a}$ with the first part of the assumed conjunction (3.173), i.e. with the assumed irreflexivity of R, we have a contradiction also in case the second, third or fourth part of the disjunction (3.175) is true. Thus, the proof of the implication '$\Rightarrow$' via contradiction is complete.

We now prove the second part ('$\Leftarrow$') of the proposed equivalence also by contradiction, assuming

$$\begin{aligned} &\forall a, b\,(a, b \in X \Rightarrow [(a\,R\,b\ \vee\ b\,R\,a\ \vee\ a = b) \\ &\quad \wedge\ \neg(a\,R\,b\ \wedge\ b\,R\,a)\ \wedge\ \neg(a\,R\,b\ \wedge\ a = b)\ \wedge\ \neg(b\,R\,a\ \wedge\ a = b\,)]). \end{aligned} \tag{3.176}$$

and the negation of (3.173) to be both true. We may write this negation also as

$$\neg\forall a\,(a \in X \Rightarrow \neg a\,R\,a)\ \vee\ \neg\forall a, b\,(a, b \in X \Rightarrow [a\,R\,b\ \vee\ b\,R\,a\ \vee\ a = b])$$

by means of De Morgan's Law for the conjunction. Using now the Quantifier Negation Law (1.53) as well as (1.82) in connection with the Double Negation Law, we obtain equivalently

$$\exists a\,(a \in X\ \wedge\ a\,R\,a)\ \vee\ \exists a, b\,(a, b \in X\ \wedge\ \neg[a\,R\,b\ \vee\ b\,R\,a\ \vee\ a = b]). \tag{3.177}$$

In case the first part of this disjunction is true, there exists an element in X, say $\bar{a}$, with $\bar{a}\,R\,\bar{a}$; since $\bar{a}, \bar{a} \in X$ implies with (3.176) in particular $\neg(\bar{a}\,R\,\bar{a}\ \wedge\ \bar{a}\,R\,\bar{a})$ and therefore $\neg\bar{a}\,R\,\bar{a}\ \vee\ \neg\bar{a}\,R\,\bar{a}$ with De Morgan's Law for the conjunction, so that $\neg\bar{a}\,R\,\bar{a}$ follows to be true with the Idempotent Law for the disjunction, we arrived at a contradiction with the previously found $\bar{a}\,R\,\bar{a}$. Next, in case the second part of the disjunction (3.177) holds, there are elements in X, say $\bar{a}$ and $\bar{b}$, satisfying the negation $\neg[\bar{a}\,R\,\bar{b} \vee \bar{b}\,R\,\bar{a} \vee \bar{a} = \bar{b}]$; as $\bar{a}, \bar{b} \in X$ implies with (3.176) in particular $\bar{a}\,R\,\bar{b}\ \vee\ \bar{b}\,R\,\bar{a}\ \vee\ \bar{a} = \bar{b}$, we again have a contradiction. This completes the proof of the implication '$\Leftarrow$' and thus the proof of the proposed equivalence. Since X and R were arbitrary, we may therefore conclude that the lemma holds. □

Let us apply this lemma in connection with the Propositions 3.48 & 3.50.

Corollary 3.52. *It is true for any x and y with $x \neq y$ that the singleton $R = \{(x, y)\}$ is an irreflexive, connex binary relation on $\{x, y\}$.*

In the following, we will consider standard types of binary relations which satisfy certain combinations of the properties listed in Definition 3.12.

Definition 3.13 (Equivalence relation, equivalent elements). We say for any set X that a binary relation $\sim$ on X is an *equivalence relation* on X iff $\sim$ is

1. reflexive,

2. symmetric, and
3. transitive.

We then say for any set X and any equivalence relation $\sim$ on X that two elements x_1 and x_2 of X are *equivalent* under $\sim$ iff

$$x_1 \sim x_2. \tag{3.178}$$

Corollary 3.45 and Proposition 3.47 give immediately the following basic examples for an equivalence relation.

Corollary 3.53. *The empty binary relation $\sim = \emptyset$ on $X = \emptyset$ is an equivalence relation.*

Corollary 3.54. *For any x it is true that the binary relation $\sim = \{(x,x)\}$ on $\{x\}$ is an equivalence relation.*

Proposition 3.55. *It is true for any set X, any equivalence relation $\sim$ on X and any element x of X that there exists a unique set $[x]_\sim$ consisting of all the elements of X which are equivalent to x, in the sense that*

$$\forall y\, (y \in [x]_\sim \Leftrightarrow y \sim x). \tag{3.179}$$

Proof. We let X and $\sim$ be arbitrary sets and assume $\sim$ to be an equivalence relation on X. Concerning a), letting x be arbitrary and assuming $x \in X$ to be true, we see in light of the Axiom of Specification and the Equality Criterion for sets that there exists a unique set $[x]_\sim$ satisfying

$$\forall y\, (y \in [x]_\sim \Leftrightarrow [y \in X \wedge y \sim x]). \tag{3.180}$$

In order to prove that the unique set $[x]_\sim$ satisfies (3.179), we take an arbitrary y. On the one hand, the assumption $y \in [x]_\sim$ implies especially $y \sim x$ with (3.180), so that the first part ('$\Rightarrow$') of the equivalence in (3.179) holds. To establish the second part ('$\Leftarrow$'), we assume now $y \sim x$ to be true, which we may write also as $(y,x) \in \sim$. Since $\sim$ is an equivalence relation on X, the inclusion $\sim \subseteq X \times X$ holds, so that the preceding finding implies $(y,x) \in X \times X$ by definition of a subset. We thus have in particular $y \in X$ by definition of the Cartesian product of two sets, and this implies in conjunction with $y \sim x$ because of (3.180) that $y \in [x]_\sim$ is true. Since y is arbitrary, we may therefore conclude that $[x]_\sim$ satisfies indeed the universal sentence (3.179), and as x, X and $\sim$ were also arbitrary, we may then further conclude that the proposed universal sentence holds. $\square$

Definition 3.14 (Equivalence class, representative). We call for any set X, for any equivalence relation $\sim$ on X and for any element $x \in X$ the set

$$[x]_\sim = [x]_{\sim_X} \tag{3.181}$$

consisting of all the elements of X that are equivalent to x the *equivalence class* of x with respect to $\sim$. Furthermore, we call any element of an equivalence class a *representative* of that equivalence class.

Corollary 3.56. *It is true for any set X and any equivalence relation $\sim$ on X that the equivalence class of any element of X is included in X, i.e.*

$$\forall x\,(x \in X \Rightarrow [x]_\sim \subseteq X). \tag{3.182}$$

Proof. Letting X, $\sim$ and x be arbitrary such that $\sim$ is an equivalence relation on X and such that x is an element of X, we observe in light of (3.180) $y \in [x]_\sim$ implies especially $y \in X$ for an arbitrary y, so that the inclusion $[x]_\sim \subseteq X$ follows to be true by definition of a subset. Because X, $\sim$ and x are also arbitrary, we may therefore conclude that the proposed sentence holds. □

Corollary 3.57. *It is true for any set X and any equivalence relation $\sim$ on X that any element of X is contained in its own equivalence class, i.e.*

$$\forall x\,(x \in X \Rightarrow x \in [x]_\sim). \tag{3.183}$$

Proof. We take arbitrary sets X, $\sim$ and x, assuming $\sim$ to be an equivalence relation on X and assuming x to be an element of X. We therefore obtain with Property 1 of an equivalence relation (i.e., with the reflexivity of $\sim$) the true sentence $x \sim x$, which implies $x \in [x]_\sim$ with (3.179). As the sets X, $\sim$ and x were initially arbitrary, we may infer from this finding the truth of the proposed universal sentence. □

Note 3.4. Corollary 3.57 shows that every equivalence class $[x]_\sim$ contains x and thus some element of X, so that we have

$$\forall x\,(x \in X \Rightarrow [x]_\sim \neq \emptyset) \tag{3.184}$$

according to (2.42).

Theorem 3.58 (Equality Criterion for equivalence classes). *It is true for any equivalence relation $\sim$ on any set X that the equivalence classes of two elements x and y in X are identical iff x and y are equivalent, i.e.*

$$\forall x, y\,(x, y \in X \Rightarrow ([x]_\sim = [y]_\sim \Leftrightarrow x \sim y)). \tag{3.185}$$

Proof. We let X and $\sim$ be arbitrary sets, we assume $\sim$ to be an equivalence relation on X, and we assume $\bar{x}, \bar{y} \in X$ to be true. We establish the first part ('$\Rightarrow$') of the equivalence in (3.185) by contraposition, assuming the negation $\neg \bar{x} \sim \bar{y}$ to be true. This assumption implies then with (3.179) and the Law of Contraposition that $\bar{x} \notin [\bar{y}]_\sim$ holds. Since $\bar{x} \in [\bar{x}]_\sim$ is also true according to (3.183), we obtain the true disjunction $\bar{x} \in [\bar{x}]_\sim \wedge \bar{x} \notin [\bar{y}]_\sim$. Let us observe that the existential sentence

$$\exists x\,([x \in [\bar{x}]_\sim \wedge x \notin [\bar{y}]_\sim] \vee [x \in [\bar{y}]_\sim \wedge x \notin [\bar{x}]_\sim])$$

is then also true, and that this sentence implies $[\bar{x}]_\sim \neq [\bar{y}]_\sim$ due to (2.23). We thus completed the proof of the implication '$\Rightarrow$' by contraposition.

We establish the second implication '$\Leftarrow$' directly, assuming $\bar{x} \sim \bar{y}$ to be true. Next, we apply the Equality Criterion for sets to prove the equation $[\bar{x}]_\sim = [\bar{x}]_\sim$, by verifying the universal sentence

$$\forall z\,(z \in [\bar{x}]_\sim \Leftrightarrow z \in [\bar{y}]_\sim). \tag{3.186}$$

For this purpose, we let z be arbitrary and assume first $z \in [\bar{x}]_\sim$ to be true. Thus, z is equivalent to $\bar{x}$, i.e. $z \sim \bar{x}$ holds according to (3.179). In conjunction with the assumed $\bar{x} \sim \bar{y}$, this implies then $z \sim \bar{y}$ with Property 3 of an equivalence relation (i.e., with the transitivity of $\sim$). This finding gives us then the desired consequent $z \in [\bar{y}]_\sim$ by applying again (3.179). We now conversely assume $z \in [\bar{y}]_\sim$ to be true, so that $z \sim \bar{y}$ holds evidently. Let us observe now that the assumed $\bar{x} \sim \bar{y}$ implies $\bar{y} \sim \bar{x}$ with Property 2 of an equivalence relation (i.e., with the symmetry of $\sim$). Then, the simultaneous truth of $z \sim \bar{y}$ and $\bar{y} \sim \bar{x}$ implies the truth of $z \sim \bar{x}$ because of the transitivity of $\sim$, with the evident consequence that $z \in [\bar{x}]_\sim$ holds, as desired. We thus completed the proof of the equivalence in (3.186), in which z is arbitrary, so that the universal sentence (3.186) follows to be true. Consequently, the equation $[\bar{x}]_\sim = [\bar{x}]_\sim$ holds indeed, and this finding completes the proof of the second part ('$\Leftarrow$') of the equivalence in (3.185).

Since X, $\sim$, $\bar{a}$ and $\bar{b}$ were initially arbitrary, we may therefore conclude that the stated theorem holds. □

Exercise 3.25. Show for any equivalence relation $\sim$ on any set X that the equivalence classes of two elements x and y in X are not disjoint iff x and y are equivalent, i.e.

$$\forall x, y\,(x, y \in X \Rightarrow ([x]_\sim \cap [y]_\sim \neq \emptyset \Leftrightarrow x \sim y)). \tag{3.187}$$

(Hint: Prove the implications directly, applying (2.42), (2.57) and some of the arguments of the proof of the Equality Criterion for equivalence classes.)

Combining the equivalences in (3.185) and (3.187) gives us the following alternative characterization of equality and non-disjointness of two equivalence classes.

Corollary 3.59. *It is true for any equivalence relation $\sim$ on any set X that the equivalence classes of two elements in X are identical iff they are not disjoint, i.e.*

$$\forall x, y\,(x, y \in X \Rightarrow ([x]_\sim = [y]_\sim \Leftrightarrow [x]_\sim \cap [y]_\sim \neq \emptyset)). \tag{3.188}$$

Note 3.5. The preceding Corollary 3.59 shows that two equivalence classes are either identical or disjoint, because equality and disjointness cannot occur concurrently.

Proposition 3.60. *It is true for any equivalence relation $\sim$ on any set X that there exists a unique set (system) $X/\sim$ consisting of all the equivalence classes $[x]_\sim$ with $x \in X$, in the sense that*

$$\forall Z\,(Z \in X/\sim\ \Leftrightarrow \exists x\,(x \in X \ \wedge\ [x]_\sim = Z)). \tag{3.189}$$

Proof. Letting X and $\sim$ be arbitrary sets such that $\sim$ is an equivalence relation of X, we obtain by means of the Axiom of Specification and the Equality Criterion for sets a unique set $X/\sim$ whose elements satisfy

$$\forall Z\,(Z \in X/\sim\ \Leftrightarrow [Z \in \mathcal{P}(X) \ \wedge\ \exists x\,(x \in X \ \wedge\ [x]_\sim = Z)]). \tag{3.190}$$

Letting Z be arbitrary, we note on the one hand that $Z \in X/\sim$ yields in particular the existential sentence in (3.189) in view of (3.190). On the other hand, assuming that there exists a constant, say $\bar{x}$, with $\bar{x} \in X$ and $[\bar{x}]_\sim = Z$, we see that (3.182) gives the inclusion $[Z =]\ [\bar{x}]_\sim \subseteq X$. We therefore have $Z \in \mathcal{P}(X)$ by definition of a power set, which finding implies in conjunction with the assumed existential sentence that $Z \in X/\sim$ is true, according to (3.190). We thus completed the proof of the equivalence in (3.189), where Z was arbitrary, so that the universal sentence (3.189) holds, too. Since X and $\sim$ are also arbitrary, the stated proposition follows therefore to be true. □

Definition 3.15 (Quotient set). We say for any set X and any equivalence relation $\sim$ on X that the set

$$X/\sim \tag{3.191}$$

consisting of all equivalence classes with respect to $\sim$ is the *quotient set* of X with respect to $\sim$.

Theorem 3.61 (Partitioning Property of quotient sets). *It is true that the quotient set $X/\sim$ of any set X with respect to any equivalence relation $\sim$ on X constitutes a partition of X, i.e.*

$$\forall A, B\,([A, B \in X/\sim \;\wedge A \neq B] \Rightarrow A \cap B = \emptyset) \;\wedge\; \bigcup X/\sim\, = X. \tag{3.192}$$

Proof. We take arbitrary sets X and $\sim$ such that $\sim$ is an equivalence relation on X. Then, the quotient set $X/\sim$ is defined and constitutes a subset of $\mathcal{P}(X)$ in view of (3.190), noting that $Z \in X/\sim$ implies in particular $Z \in \mathcal{P}(X)$ for any Z. Thus, $X/\sim$ is by definition of a power set a system of subsets of X.

We now show that all sets in this set system are disjoint, letting $A, B \in X/\sim$ be arbitrary such that $A \neq B$ holds. Due to (3.189), the preceding assumption $A \in X/\sim$ implies that there exists a constant, say $\bar{x}$, satisfying $\bar{x} \in X$ and $[\bar{x}]_\sim = A$. Similarly, the assumed $B \in X/\sim$ implies the existence of a particular constant $\bar{y} \in X$ with $[\bar{y}]_\sim = B$. Then, the other assumption $A \neq B$ yields $[\bar{x}]_\sim \neq [\bar{y}]_\sim$ via substitution, and this finding further implies $\neg[\bar{x}]_\sim \cap [\bar{y}]_\sim \neq \emptyset$ with (3.188) and the Law of Contraposition. Consequently, we obtain $[\bar{x}]_\sim \cap [\bar{y}]_\sim = \emptyset$ with the Double Negation Law, so that substitutions gives us the desired equation $A \cap B = \emptyset$, proving the implication in (3.192). Since A and B are arbitrary, we may therefore conclude that the universal sentence in (3.192) is true, which means that the sets in $X/\sim$ are indeed pairwise disjoint.

Next, we verify that the union of the set system $X/\sim$ is identical with X. To do this, we apply the Equality Criterion for sets and prove accordingly the universal sentence

$$\forall c\,(c \in \bigcup X/\sim\, \Leftrightarrow c \in X), \tag{3.193}$$

letting c be arbitrary. Regarding the first part ('$\Rightarrow$') of the equivalence, we assume $c \in \bigcup X/\sim$ to be true, which means by definition of the union of a set system that $c \in \bar{A}$ holds for some particular set $\bar{A} \in X/\sim$. According to (3.189) there exists then a particular element $\bar{x} \in X$ such that $[\bar{x}]_\sim = \bar{A}$. We therefore obtain $[\bar{x}]_\sim \subseteq X$ by means of (3.182), as well as $c \in [\bar{x}]_\sim$ via substitution. Consequently, the definition of a subset yields $c \in X$, as desired. Regarding the second part ('$\Leftarrow$') of the equivalence, we assume conversely $c \in X$ to be true, which gives us $c \in [c]_\sim$ with (3.183), and the simultaneous truth of $c \in X$ and of $[c]_\sim = [c]_\sim$ demonstrates that there exists a constant x satisfying both $x \in X$ and $[x]_\sim = [c]_\sim$. This existential sentence implies now with (3.189) that $[c]_\sim \in X/\sim$ is true. In conjunction with the previously established $c \in [c]_\sim$, this shows in light of the definition of the union of a set system that there exists a set $A \in X/\sim$ that contains c, with the desired consequence that $c \in \bigcup X/\sim$ holds. We thus completed the proof of the equivalence in (3.193), and as c was arbitrary, we may now infer from the truth of that equivalence the truth of the universal sentence (3.193), and therefore the truth of the equation $\bigcup X/\sim = X$ in (3.192).

We thus proved both parts of the conjunction (3.192), in which X and $\sim$ were arbitrary, so that the stated theorem is indeed true. □

The following kind of binary relation will be used frequently throughout this exposition.

Definition 3.16 (Reflexive partial ordering, partially ordered set / poset). For any set X we say that a binary relation R on X is a *reflexive partial ordering* of X iff R is

1. reflexive,
2. antisymmetric, and
3. transitive.

We then call the ordered pair (X, R) a *partially ordered set* or a *poset*.

Corollary 3.62. *The empty binary relation $R = \emptyset$ on $X = \emptyset$ is a reflexive partial ordering of $\emptyset$, and*

$$(\emptyset, \emptyset) \tag{3.194}$$

is a partially ordered set.

Corollary 3.63. *For any x it is true that the binary relation $R = \{(x, x)\}$ on $\{x\}$ is a reflexive partial ordering of $\{x\}$, and*

$$(\{x\}, \{(x, x)\}) \tag{3.195}$$

is a partially ordered set.

Theorem 3.64 (Reflexive partial ordering of inclusion ($\subseteq$)). *It is true for any set system $\mathcal{K}$ that there exists a unique set $\subseteq_{\mathcal{K}}$ such that an element Y is in $\subseteq_{\mathcal{K}}$ iff there exists an ordered pair (A, B) in the Cartesian product of $\mathcal{K}$ with itself such that A is included in B, i.e. iff*

$$\forall Y\,(Y \in \subseteq_{\mathcal{K}} \Leftrightarrow [Y \in \mathcal{K} \times \mathcal{K} \wedge \exists A, B\,(A \subseteq B \wedge (A, B) = Y)]). \tag{3.196}$$

Then, the set $\subseteq_{\mathcal{K}}$ is a reflexive partial ordering of $\mathcal{K}$ and satisfies

$$\forall A, B\,(A, B \in \mathcal{K} \Rightarrow [A \subseteq_{\mathcal{K}} B \Leftrightarrow A \subseteq B]). \tag{3.197}$$

Proof. Letting $\mathcal{K}$ be an arbitrary set system, we may evidently apply the Axiom of Specification in connection with the Equality Criterion for sets to establish the unique existence sentence of a set $\subseteq_{\mathcal{K}}$ satisfying (3.196) holds.

Next, we verify that $\subseteq_{\mathcal{K}}$ is a binary relation on $\mathcal{K}$, i.e. $\subseteq_{\mathcal{K}} \subseteq \mathcal{K} \times \mathcal{K}$. For this purpose, we apply the definition of a subset and prove the equivalent universal sentence

$$\forall Y\,(Y \in \subseteq_{\mathcal{K}} \Rightarrow Y \in \mathcal{K} \times \mathcal{K}), \tag{3.198}$$

letting Y be arbitrary and assuming $Y \in \subseteq_{\mathcal{K}}$ to be true. This assumption implies with (3.196) in particular $Y \in \mathcal{K} \times \mathcal{K}$, completing the proof of the implication in (3.198). As Y is arbitrary, we may therefore conclude that the universal sentence (3.198) holds, which means $\subseteq_{\mathcal{K}} \subseteq \mathcal{K} \times \mathcal{K}$ (by definition of a subset). Thus, $\subseteq_{\mathcal{K}}$ is indeed a binary relation on $\mathcal{K}$, by definition.

To demonstrate that the universal sentence (3.197) is true for the binary relation $\subseteq_{\mathcal{K}}$, we take arbitrary sets $\bar{A}$ and $\bar{B}$, and we assume $\bar{A}, \bar{B} \in \mathcal{K}$ to be true. To establish now the first part ('$\Rightarrow$') of the equivalence in (3.197), we assume $\bar{A} \subseteq_{\mathcal{K}} \bar{B}$, which assumption we may write also as $(\bar{A}, \bar{B}) \in \subseteq_{\mathcal{K}}$. This in turn implies with (3.196) especially that there constants, say $\bar{\bar{A}}$ and $\bar{\bar{B}}$, such that $\bar{\bar{A}} \subseteq \bar{\bar{B}}$ and $(\bar{\bar{A}}, \bar{\bar{B}}) = (\bar{A}, \bar{B})$ are both true. Then, the latter equation gives with the Equality Criterion for ordered pairs $\bar{\bar{A}} = \bar{A}$ as well as $\bar{\bar{B}} = \bar{B}$, so that the former inclusion yields via substitutions $\bar{A} \subseteq \bar{B}$, as desired. Thus, the first part of the equivalence to be proven holds.

Regarding the second part ('$\Leftarrow$'), we now assume $\bar{A} \subseteq \bar{B}$ to be true, which assumption shows in light of the obviously true equation $(\bar{A}, \bar{B}) = (\bar{A}, \bar{B})$ that the existential sentence

$$\exists A, B\,(A \subseteq B \,\wedge\, (A, B) = (\bar{A}, \bar{B}))$$

holds. Furthermore, the initial assumption $\bar{A}, \bar{B} \in \mathcal{K}$ implies $(\bar{A}, \bar{B}) \in \mathcal{K} \times \mathcal{K}$ by definition of the Cartesian product of two sets, and this finding implies then together with the preceding existential sentence the truth of $(\bar{A}, \bar{B}) \in \subseteq_{\mathcal{K}}$ with (3.196). We already established $\subseteq_{\mathcal{K}}$ as a binary relation, so that we may write this also as $\bar{A} \subseteq_{\mathcal{K}} \bar{B}$, completing the proof of the equivalence in (3.197). Since A and B were arbitrary, we may therefore conclude that the proposed universal sentence (3.197) is indeed true.

It now remains for us to verify that $\subseteq_{\mathcal{K}}$ is a reflexive partial ordering of $\subseteq_{\mathcal{K}}$. We first prove that $\subseteq_{\mathcal{K}}$ is reflexive and verify accordingly

$$\forall A\,(A \in \mathcal{K} \Rightarrow A \subseteq_{\mathcal{K}} A). \tag{3.199}$$

We let A be an arbitrary set, we assume $A \in \mathcal{K}$ to be true, and we observe that $A \subseteq A$ holds according to (2.10). Because of (3.197), we then obtain immediately the desired consequent $A \subseteq_{\mathcal{K}} A$, and since A was arbitrary, we may therefore conclude that the universal sentence (3.199) holds, which means that $\subseteq_{\mathcal{K}}$ is a reflexive binary relation on $\mathcal{K}$, by definition.

Concerning the antisymmetry of $\subseteq_{\mathcal{K}}$, we need to verify

$$\forall A, B\,(A, B \in \mathcal{K} \Rightarrow [(A \subseteq_{\mathcal{K}} B \,\wedge\, B \subseteq_{\mathcal{K}} A) \Rightarrow A = B]). \tag{3.200}$$

To do this, we let A and B be arbitrary sets, assume $A, B \in \mathcal{K}$ to be true, and assume in addition that $A \subseteq_{\mathcal{K}} B$ and $B \subseteq_{\mathcal{K}} A$ both hold. The latter two assumptions immediately imply $A \subseteq B$ and $B \subseteq A$, respectively, in view of (3.197). Consequently, the conjunction $A \subseteq B \,\wedge\, B \subseteq A$ is true, which implies then the true equation $A = B$ with the Axiom of Extension. Thus, the proofs of the implications in (3.200) are complete, and as A and B were arbitrary, we may therefore conclude that the universal sentence (3.200) holds, so that $\subseteq_{\mathcal{K}}$ is indeed an antisymmetric binary relation on $\mathcal{K}$.

Finally, we demonstrate that $\subseteq_{\mathcal{K}}$ is transitive, i.e. that $\subseteq_{\mathcal{K}}$ satisfies the universal sentence

$$\forall A, B, C\,(A, B, C \in \mathcal{K} \Rightarrow [(A \subseteq_{\mathcal{K}} B \,\wedge\, B \subseteq_{\mathcal{K}} C) \Rightarrow A \subseteq_{\mathcal{K}} C]). \tag{3.201}$$

Letting A, B, C be arbitrary, assuming $A, B, C \in \mathcal{K}$ to be true, and assuming also $A \subseteq_{\mathcal{K}} B$ as well as $B \subseteq_{\mathcal{K}} C$ to hold, we obtain the inclusions $A \subseteq B$ and $B \subseteq C$ with (3.197). Thus, the conjunction $A \subseteq B \,\wedge\, B \subseteq C$ is true, which in turn implies $A \subseteq C$ with (2.13). The latter inclusion now gives the desired $A \subseteq_{\mathcal{K}} C$ again with (3.197), and since A, B and C are arbitrary, the universal sentence (3.201) follows also to be true. Thus, $\subseteq_{\mathcal{K}}$ is a transitive binary relation by definition, and because $\subseteq_{\mathcal{K}}$ is reflexive and antisymmetric as well, it is a reflexive binary relation by definition.

Since $\mathcal{K}$ was initially arbitrary, we may now finally conclude that the stated theorem is true. □

The properties of a reflexively-partially ordered set also hold for any 'subset' of such an ordered set.

Theorem 3.65 (Reflexive partial ordering of subsets). *The following sentences are true for any set X, for any reflexive partial ordering R of X, and for any subset $A \subseteq X$.*

a) There exists a unique set R_A consisting of all the ordered pairs in R whose components are elements of A, that is,

$$\exists! R_A\, \forall Z\,(Z \in R_A \Leftrightarrow [Z \in R \,\wedge\, \exists x, y\,(x, y \in A \,\wedge\, (x, y) = Z)]). \tag{3.202}$$

b) Then, R_A is a binary relation on X, which is included in R, i.e.

$$R_A \subseteq R, \tag{3.203}$$

and which satisfies

$$\forall x, y\,(x, y \in A \Rightarrow [x\,R_A\,y \Leftrightarrow x\,R\,y]). \tag{3.204}$$

c) Furthermore, R_A is a reflexive partial ordering of A.

Proof. We let X, R and A be arbitrary sets, we assume that R is a reflexive partial ordering of X, and we assume that A is a subset of X.

Concerning a), we may evidently apply the Axiom of Specification together with the Equality Criterion for sets to establish the stated uniquely existential sentence. Thus, the set R_A satisfies

$$\forall Z\,(Z \in R_A \Leftrightarrow [Z \in R \wedge \exists x, y\,(x, y \in A \wedge (x, y) = Z)]). \tag{3.205}$$

Concerning b), we observe in light of (3.205) that $Z \in R_A$ implies in particular $Z \in R$ for any Z, so that the inclusion (3.203) holds by definition of a subset. Furthermore, the reflexive partial ordering R of X is by definition a binary relation on X, so that $R \subseteq X \times X$ also holds. The previous two inclusions then give the inclusion $R_A \subseteq X \times X$ with (2.13), which means that R_A is a binary relation on X. We now take arbitrary constants $\bar{x}$ and $\bar{y}$, and we assume $\bar{x}, \bar{y} \in A$ to be true. To prove the first part ('$\Rightarrow$') of the equivalence in (3.204), we assume now also that $\bar{x}\,R_A\,\bar{y}$ holds. We may write this assumption also as $(\bar{x}, \bar{y}) \in R_A$, which in turn implies $(\bar{x}, \bar{y}) \in R$ with (3.203) by definition of a subset. Since R is a binary relation, we may write the latter also as $\bar{x}\,R\,\bar{y}$, so that the proof of the first part of the equivalence is complete. To prove the second part ('$\Leftarrow$'), we now assume conversely $\bar{x}\,R\,\bar{y}$ to be true, that is, $(\bar{x}, \bar{y}) \in R$. The initial assumption $\bar{x}, \bar{y} \in A$ clearly shows that there exist constants x and y such that $x, y \in A$ and $(x, y) = (\bar{x}, \bar{y})$ are both true. Then, $(\bar{x}, \bar{y}) \in R$ implies together with this existential sentence that $(\bar{x}, \bar{y}) \in R_A$ holds, according to (3.205), which we may write also as $\bar{x}\,R_A\,\bar{y}$ (recalling that R_A is a binary relation). Thus, the second part of the equivalence is also true, and since $\bar{x}, \bar{y}$ were arbitrary, we may therefore conclude that the universal sentence (3.204) holds.

Concerning c), we first verify that R_A is a binary relation on A, i.e. that the inclusion $R_A \subseteq A \times A$ holds. For this purpose, we take an arbitrary set Z and assume $Z \in R_A$ to be true. This assumption implies now with (3.205) in particular that there exist constants, say $\bar{x}$ and $\bar{y}$, such that $\bar{x}, \bar{y} \in A$ and $(\bar{x}, \bar{y}) = Z$ are both true. The former yields $(\bar{x}, \bar{y}) \in A \times A$ with the definition of the Cartesian product of two sets, so that substitution based on the latter equation gives $Z \in A \times A$. Since Z is arbitrary, we may infer from this finding that $Z \in R_A$ implies $Z \in A \times A$ for any set Z, so that $R_A \subseteq A \times A$ is indeed true (by definition of a subset). Thus, R_A is a binary relation on A by definition.

Let us check that R_A is reflexive, letting x be arbitrary and assuming $x \in A$ to be true. Then, the initially assumed inclusion $A \subseteq X$ evidently yields $x \in X$, and this implies $x\,R\,x$ since we assumed R to be a reflexive partial ordering of X. Because of (3.204), the previous finding further implies $x\,R_A\,x$. As x was arbitrary, we may therefore infer from this the reflexivity of R_A.

Regarding the antisymmetry, we take arbitrary $x, y \in A$ such that $x\,R_A\,y$ and $y\,R_A\,x$ are both true. Clearly, we then obtain $x, y \in X$ and consequently $x\,R\,y$ as well as $y\,R\,x$. As the reflexive partial ordering R is antisymmetric, we get the desired equation $x = y$, and since x and y are arbitrary, we may therefore conclude that R_A is indeed antisymmetric.

Finally, we demonstrate that R_A is transitive, by letting $x, y, z \in A$ be arbitrary such that $x\,R_A\,y$ and $y\,R_A\,z$ hold. Evidently, $x, y, z \in X$ is then also true, with the consequence that $x\,R\,y$ and $y\,R\,z$ both hold. Since the reflexive partial ordering R is transitive, we obtain $x\,R\,z$ and therefore $x\,R_A\,z$, as desired. Here, x, y and z were arbitrary, so that R_A follows to be transitive as well.

We thus proved that the binary relation R_A on A is a reflexive partial ordering of A. Because the sets X, R and A were initially arbitrary, we may now finally conclude that the stated theorem is true. □

We continue now with another basic kind of binary ordering relation, which we will encounter mainly in the context of number systems. The main idea is to replace the previously considered reflexivity property by irreflexivity.

Definition 3.17 (Irreflexive partial ordering, less than). For any set X we say that a binary relation $<$ on X is an *irreflexive partial ordering* of X iff $<$ is

1. irreflexive and
2. transitive.

We then call the ordered pair

$$(X, <) \tag{3.206}$$

also a *partially ordered set* or a *poset*. Furthermore, we say for any elements a, b of X that a is *less than* b iff $a < b$.

Corollary 3.66. *For any set X the empty binary relation $R = \emptyset$ on X is an irreflexive partial ordering of X, and*

$$(X, \emptyset) \tag{3.207}$$

is a partially ordered set.

Proposition 3.67. *For any set X and any irreflexive partial ordering $<$ of X it is true that if an element a of X is less than an element b of X, then a and b are different, i.e.*

$$\forall a, b\,(a, b \in X \Rightarrow [a < b \Rightarrow a \neq b]). \tag{3.208}$$

Proof. We let X be an arbitrary set, $<$ an arbitrary irreflexive partial ordering of X, let a and b be arbitrary, and assume further $a, b \in X$ to hold. Next, we prove the implication $a < b \Rightarrow a \neq b$ by contradiction, assuming $a < b$ and $\neg a \neq b$ to be true. The latter means $\neg(\neg a = b)$ and therefore implies $a = b$ with the Double Negation Law. With this equation, the assumed $a < b$ becomes $a < a$ after substitution. Since $\neg a < a$ is also true in view of the irreflexivity of $<$, we thus obtained a contradiction according to (1.11), which proves the implications in (3.208). Since X, $<$, a and b were arbitrary, the proposed universal sentence follows to be true. □

Exercise 3.26. Verify the following universal sentence for any set X and any irreflexive partial ordering $<$ of X.

$$\forall a, b\,(a, b \in X \Rightarrow \neg(a < b \,\wedge\, b < a)). \tag{3.209}$$

(Hint: Apply Method 1.11 in connection with Definition 3.17.)

We now state a similar version of Reflexive partial orderings of subsets in the context of irreflexive partial orderings.

Theorem 3.68 (Irreflexive partial ordering of subsets). *The following sentences are true for any set X, for any irreflexive partial ordering $<_X$ of X, and for any subset $A \subseteq X$.*

a) *There exists a unique set $<_A$ consisting of all the ordered pairs in $<_X$ whose components are elements of A, that is,*

$$\exists! <_A \forall Z\,(Z \in <_A \Leftrightarrow [Z \in <_X \,\wedge \exists x, y\,(x, y \in A \,\wedge\, (x, y) = Z)]). \tag{3.210}$$

b) *Then, $<_A$ is a binary relation on X, which is included in R, i.e.*

$$<_A \subseteq <_X, \tag{3.211}$$

and which satisfies

$$\forall x, y\,(x, y \in A \Rightarrow [x <_A y \Leftrightarrow x <_X y]). \tag{3.212}$$

c) Furthermore, $<_A$ is an irreflexive partial ordering of A.

Exercise 3.27. Prove Theorem 3.68.

(Hint: Proceed in analogy to the proof of Theorem 3.65; use the Law of Contraposition.)

Special forms of reflexive and irreflexive partial orderings are the 'total' and the 'linear' ordering, as defined in the following.

Definition 3.18 (Total ordering, totally ordered set/chain). For any set X we say that a reflexive partial ordering $\leq$ of X is a *total ordering* of X iff $\leq$ is total. We then call $(X, \leq)$ a *totally ordered set* or a *chain*.

Corollary 3.69. *The empty binary relation $R = \emptyset$ on $\emptyset$ is a total ordering of $\emptyset$, and*

$$(\emptyset, \emptyset) \tag{3.213}$$

is a totally ordered set.

To obtain another simple example, we recall Corollary 3.63 and Proposition 3.47.

Corollary 3.70. *For any x it is true that the binary relation $R = \{(x,x)\}$ on $\{x\}$ is a total ordering of $\{x\}$, and*

$$(\{x\}, \{(x,x)\}) \tag{3.214}$$

is a totally ordered set.

Theorem 3.71 (Total ordering of subsets). *For any totally ordered set $(X, \leq)$ and any subset $A \subseteq X$, it is true that the set $(A, \leq_A)$ is also totally ordered.*

Proof. We let X, $\leq$ and A be arbitrary sets such that $\leq$ is a total ordering of X and such that A is included in X. Thus, $\leq$ is a reflexive partial ordering of X, so that there exists the unique reflexive partial ordering $\leq_A$ of A according to Theorem 3.65. It thus remains for us to show that $\leq_A$ is total, i.e. that $\leq_A$ satisfies

$$\forall a, b\,(a, b \in A \Rightarrow [a \leq_A b \,\vee\, b \leq_A a]). \tag{3.215}$$

To do this, we let a and b be arbitrary and assume $a, b \in A$ to be true. Then, the assumption $A \subseteq X$ yields (by definition of a subset) $a, b \in X$ and therefore $a \leq b \,\vee\, b \leq a$ due to the totality of $\leq$. Based on this true disjunction, we now prove the disjunction in (3.215) by cases. In the first case $a \leq b$, we obtain with (3.204) from the assumed $a, b \in A$ the true inequality $a \leq_A b$. Then, the disjunction to be proven is evidently also true. Similarly, the second case $b \leq a$ yields $b \leq_A a$ and therefore the truth of the disjunction in (3.215), completing the proof by cases. Since a and b are arbitrary, we may therefore conclude that the universal sentence (3.215) is true, which means that the binary relation $\leq_A$ is indeed total. Thus, $\leq_A$ is a total ordering of A, and as the sets X, $\leq$ and A were initially arbitrary, we may infer from this finding the truth of the stated theorem. □

Definition 3.19 (Linear ordering, linearly ordered set). For any set X we say that an irreflexive partial ordering $<$ on X is a *linear ordering* of X iff $<$ is connex. We then call $(X, <)$ a *linearly ordered set*.

Note 3.6. For future reference, any linear ordering $<$ of a set X is

1. irreflexive, i.e. satisfies
$$\forall a\,(a \in X \Rightarrow \neg a < a), \tag{3.216}$$
2. connex, i.e. satisfies
$$\forall a, b\,(a, b \in X \Rightarrow [a < b \,\vee\, b < a \,\vee\, a = b]), \tag{3.217}$$
and
3. transitive, i.e. satisfies
$$\forall a, b, c\,(a, b, c \in X \Rightarrow [(a < b \,\wedge\, b < c) \Rightarrow a < c]). \tag{3.218}$$

Corollary 3.72. *The empty binary relation $R = \emptyset$ on $\emptyset$ is a linear ordering of $\emptyset$, and*
$$(\emptyset, \emptyset) \tag{3.219}$$
is a linearly ordered set.

Combining Corollary 3.66 with the finding of Exercise 3.24 yields the following nontrivial example for a linearly ordered set.

Corollary 3.73. *For any x the empty binary relation $R = \emptyset$ on $\{x\}$ is a linear ordering of $\{x\}$, and*
$$(\{x\}, \emptyset) \tag{3.220}$$
is a linearly ordered set.

Another simple example is immediately derived from Proposition 3.48 and Corollary 3.52.

Corollary 3.74. *For any x and y satisfying $x \neq y$ it is true that the singleton $R = \{(x,y)\}$ is a linear ordering of $\{x,y\}$, and*

$$(\{x,y\},\{(x,y)\}) \tag{3.221}$$

is a linearly ordered set.

It is possible replace Property 1 and Property 2 of a linearly ordered set by the equivalent property of comparability.

Theorem 3.75 (Characterization of linearly ordered sets). *For any set X and any binary relation $<$ on X, it is true that $<$ is a linear ordering of X iff*

2. $<$ is comparable, that is,*

$$\begin{aligned}\forall a,b\,(a,b \in X \Rightarrow [(a < b \,\vee\, b < a \,\vee\, a = b) \\ \wedge\, \neg(a < b \,\wedge\, b < a) \,\wedge\, \neg(a < b \,\wedge\, a = b) \wedge \neg(b < a \,\wedge\, a = b\,)]),\end{aligned} \tag{3.222}$$

and if

3. $<$ is transitive, that is,

$$\forall a,b,c\,(a,b,c \in X \Rightarrow [(a < b \,\wedge\, b < c) \Rightarrow a < c]). \tag{3.223}$$

Proof. We let X be an arbitrary set and $<$ an arbitrary binary relation. On the one hand, if the ordered pair $(X,<)$ is linearly ordered, then $<$ is by definition irreflexive, connex, and transitive. It then follows with Lemma 3.51 from the irreflexivity and the connexity that $<$ is also comparable. Thus, Property 2* and Property 3 hold, so that the proof of the first part of the proposed equivalence is complete. On the other hand, if $<$ is comparable and transitive, then it follows with Lemma 3.51 from the comparability of $<$ that $<$ is also irreflexive and connex. Together with the transitivity of $<$, this shows that $<$ is a linear ordering of X, which finding completes the proof of the equivalence. Since X and $<$ were arbitrary, the theorem follows then to be true. □

Note 3.7. Theorem 3.49 shows for any linearly ordered set $(X,<)$ in light of Property 2* that precisely one of the three sentences $a < b$, $b < a$ and $a = b$ is true for any elements a,b in X, that is,

$$\begin{aligned}&(a < b \,\wedge\, [\neg b < a] \,\wedge\, a \neq b)) \\ &\vee\, ([\neg a < b] \,\wedge\, b < a \,\wedge\, a \neq b) \\ &\vee\, ([\neg a < b] \,\wedge\, [\neg b < a] \,\wedge\, a = b).\end{aligned} \tag{3.224}$$

Theorem 3.76 (Linear ordering of subsets). *For any linearly ordered set $(X, <)$ and any subset $A \subseteq X$ defining the irreflexive partial ordering $<_A$ according to Theorem 3.68, it is true that $(A, <_A)$ is linearly ordered.*

Exercise 3.28. Prove Theorem 3.76.
(Hint: Apply a proof similar to that of Theorem 3.71.)

The notion of comparability by means of $<$ suggests the following terminology.

Definition 3.20 (Greater than, strictly between, intermediate value, less than or equal to, greater than or equal to, between). For any set X, any irreflexive partial ordering $<$ of X and any elements $a, b, c \in X$, we say that

(1) b is *greater than* a, symbolically

$$b > a. \tag{3.225}$$

if, and only if, $a < b$.

(2) b is *strictly between* or an *intermediate value* of a and c, symbolically

$$a < b < c, \tag{3.226}$$

if, and only if $a < b$ and $b < c$.

(3) a is *less than or equal to* b, symbolically

$$a \leq b \tag{3.227}$$

if, and only if $a < b$ or $a = b$.

(4) b is *greater than or equal to* a, symbolically

$$b \geq a \tag{3.228}$$

if, and only if $a \leq b$.

(5) b is *between* a and c, symbolically

$$a \leq b \leq c, \tag{3.229}$$

if, and only if $a \leq b$ and $b \leq c$.

The following immediate consequences of the definition of $\leq$ and the properties of $<$ will be applied frequently.

Theorem 3.77 (Negation Formula for $\leq$ & for $<$). *The following laws are true for any linearly ordered set $(X, <)$.*

a) **Negation Formula for $\leq$:**

$$\forall a, b\,(a, b \in X \Rightarrow [\neg a \leq b \Leftrightarrow a > b]). \tag{3.230}$$

b) **Negation Formula for $<$:**

$$\forall a, b\,(a, b \in X \Rightarrow [\neg a < b \Leftrightarrow a \geq b]). \tag{3.231}$$

Proof. We let X and $<$ be arbitrary sets and assume further that the ordered pair $(X, <)$ is linearly ordered. Concerning a), we let a and b be arbitrary and assume that $a, b \in X$ holds. Let us now observe the truth of the equivalences

$$\begin{aligned} \neg a \leq b &\Leftrightarrow \neg(a < b \,\vee\, a = b) \\ &\Leftrightarrow \neg a < b \,\wedge\, a \neq b, \end{aligned}$$

using Definition 3.20(3) and De Morgan's Law for the disjunction. Therefore, the assumption $\neg a \leq b$ implies that $a < b$ and $a = b$ are both false. Since the linear ordering $<$ of X is connex, the disjunction of $a < b$, $b < a$ and $a = b$ is true, so that the second part $b < a$ holds. This gives the desired consequent $a > b$ of the first part of the equivalence with Definition 3.20(1). To prove the second part, we now assume $a > b$ to be true, so that $b < a$ holds. As the linear ordering $<$ is comparable, it follows with the Characterization of comparability that precisely one of the sentences $a < b$, $b < a$ and $a = b$ is true. Therefore, $a < b$ and $a = b$ are false, which means that the conjunction of $\neg a < b$ and $a \neq b$ is true, so that $\neg a \leq b$ follows to be true with the previously established equivalences. Thus, the second part of the equivalence in (3.230) also holds. Since a and b are arbitrary, we may now conclude that the universal sentence (3.230) is true, so that the proof of a) is complete. As X and $<$ are also arbitrary, we may further conclude that a) holds for any X and any $<$. □

Exercise 3.29. Prove the Negation Formula for $<$.

(Hint: Use similar arguments as in the proof of the Negation Formula for $\leq$.)

The following formulas will be applied frequently.

Theorem 3.78 (Transitivity Formula for $<$ and $\leq$ & for $\leq$ and $<$). *The following laws are true for any partially ordered set $(X, <)$.*

a) **Transitivity Formula for $<$ and $\leq$**:

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [(a < b \,\wedge\, b \leq c) \Rightarrow a < c]). \tag{3.232}$$

b) **Transitivity Formula for $\leq$ and $<$**:

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [(a \leq b \,\wedge\, b < c) \Rightarrow a < c]). \tag{3.233}$$

Proof. We let X and $<$ be arbitrary sets and assume that the ordered pair $(X, <)$ is partially ordered. Concerning a), we take arbitrary a, b and c and assume $a, b, c \in X$ to be true. We now assume furthermore that $a < b$ and $b \leq c$ both hold, where the latter means that the disjunction $b < c \vee b = c$ is true, according to Definition 3.20(3). In case the first part $b < c$ of this disjunction holds, we obtain the true conjunction $a < b \wedge b < c$, which in turn implies the desired $a < c$ with the transitivity of the partial ordering $<$ of X. In case the second part $b = c$ of the preceding disjunction holds, then the previously assumed $a < b$ yields via substitution again $a < c$, as desired. Thus, the two implications in (3.232) are true, and since a, b, c are arbitrary, the universal sentence (3.232) follows to be also true. As X and $<$ were also arbitrary, we may now further conclude that a) holds for any X and any $<$. □

Exercise 3.30. Prove the Transitivity Formula for $\leq$ and $<$.

Note 3.8. We will apply a similar notation as in (3.229) to write, for instance, $a < b \leq c$ instead of $a < b \wedge b \leq c$,

Proposition 3.79. *The following implication holds for any set X, any irreflexive partial ordering $<$ of X, and any $a, b \in X$.*

$$[\neg(a < b \,\wedge\, b < a) \,\wedge\, a \neq b] \;\Rightarrow\; \neg(a \leq b \,\wedge\, b \leq a). \tag{3.234}$$

Proof. We let X be an arbitrary set, $<$ an arbitrary irreflexive partial ordering of X, and a, b arbitrary elements. We now prove the implication by contradiction, assuming the negation $\neg(a < b \wedge b < a)$, the inequality $a \neq b$ and the double negation $\neg\neg(a \leq b \wedge b \leq a)$ to be true. The latter implies $a \leq b \wedge b \leq a$ with (1.35), which conjunction we may also write as

$$(a < b \,\vee\, a = b) \,\wedge\, (b < a \,\vee\, b = a),$$

using Definition 3.20(3). Here, $a = b$ and $b = a$ are both false in view of the assumed $a \neq b$, so that the preceding conjunction implies the truth of $a < b$ and $b < a$. Thus, $a < b \wedge b < a$ is true, and $\neg(a < b \wedge b < a)$ also holds due to Exercise 3.26, so that we obtained a contradiction. This proves the implication (3.234), and since X, $<$, a and b were arbitrary, we therefore conclude that the proposition is true. □

Proposition 3.80. *The following equivalence is true for any set X, any irreflexive partial ordering $<$ of X, and any elements $a, b \in X$.*

$$a < b \;\Leftrightarrow\; (a \leq b \,\wedge\, a \neq b) \tag{3.235}$$

Proof. We let X be an arbitrary set, $<$ an arbitrary irreflexive partial ordering of X, and a and b arbitrary elements of X.

To prove the first part ('$\Rightarrow$') of the stated equivalence, we assume $a < b$. On the one hand, the disjunction $a < b \vee a = b$ is then evidently also true (irrespective of the truth value of $a = b$), which further implies $a \leq b$ with Definition 3.20(3). On the other hand, the assumed $a < b$ implies $a \neq b$ with Proposition 3.67, which shows together with the previously established $a \leq b$ that the right-hand side of the equivalence (3.235) is true.

To prove the second part ('$\Leftarrow$') of that equivalence, we assume the conjunction

$$a \leq b \,\wedge\, a \neq b$$

to be true. Because of Definition 3.20(3) and the Commutative Law for sentences (1.36), we may write this sentence equivalently as

$$a \neq b \,\wedge\, (a < b \,\vee\, a = b).$$

Then, an application of the Distributive Law for Sentences (1.44) gives

$$(a \neq b \,\wedge\, a < b) \,\vee\, (a \neq b \,\wedge\, a = b).$$

Here, $a \neq b \wedge a = b$ is evidently a contradiction and therefore false, so that the first part $a \neq b \wedge a < b$ of the preceding disjunction is true. This conjunction then implies in particular $a < b$, so that the left-hand side of the equivalence (3.235) is true. Thus, the proof of the equivalence is complete, and since X, $<$, a and b were arbitrary, we finally conclude that the proposition holds, as claimed. □

Definition 3.21 (Densely ordered set). We say that a linearly ordered set $(X, <)$ is *densely ordered* iff

1. X is neither empty nor a singleton, that is,

$$X \neq \emptyset \,\wedge\, \forall a\,(X \neq \{a\}), \tag{3.236}$$

   and

2. for any two elements x and y in X with $x < y$ there exists an element of X which is strictly between x and y, that is,

$$\forall x, y\,([x, y \in X \,\wedge\, x < y] \Rightarrow \exists z\,(z \in X \,\wedge\, x < z < y)). \tag{3.237}$$

3.3.2. Induced partial orderings

Any given irreflexive partial ordering may be used to define a corresponding reflexive partial ordering of the same set.

Theorem 3.81 (Characterization of induced reflexive partial orderings). *The following sentences hold for any set X and any irreflexive partial ordering $<_X$ of X.*

a) There exists a unique set $\leq_X$ such that an element Z is in $\leq_X$ iff Z is in $X \times X$ and moreover if there is an ordered pair (a,b) identical with Z where a is less than b or a is equal to b, that is,

$$\exists!\leq_X \forall Z\,(Z \in \leq_X \\ \Leftrightarrow [Z \in X \times X \wedge \exists a,b\,([a <_X b \vee a = b] \wedge (a,b) = Z)]).$$

b) The set $\leq_X$ is a binary relation on X satisfying

$$\forall a,b\,(a,b \in X \Rightarrow [a \leq_X b \Leftrightarrow (a <_X b \vee a = b)]) \tag{3.238}$$

and furthermore

$$\forall a,b\,(a,b \in X \Rightarrow [a <_X b \;\Leftrightarrow\; (a \leq_X b \wedge a \neq b)]). \tag{3.239}$$

c) Moreover, the binary relation $\leq_X$ is a reflexive partial ordering of X.

Proof. Letting X be an arbitrary set and $<_X$ an arbitrary irreflexive partial ordering of X, we evidently obtain the uniquely existential sentence a) with the Axiom of Specification in connection with the Equality Criterion for sets. Thus, the set $\leq_X$ satisfies

$$\forall Z\,(Z \in \leq_X \Leftrightarrow [Z \in X \times X \wedge \exists a,b\,([a <_X b \vee a = b] \wedge (a,b) = Z)]). \tag{3.240}$$

Concerning b), letting Z be arbitrary, we see that the assumption $Z \in \leq_X$ implies with (3.240) in particular $Z \in X \times X$, so that $\leq_X \subseteq X \times X$ follows to be true by definition of a subset. Thus, $\leq_X$ is a binary relation on X by definition.

Next, regarding (3.238), we let $\bar{a}$ and $\bar{b}$ be arbitrary and assume $\bar{a},\bar{b} \in X$. To prove the first part ('$\Rightarrow$') of the equivalence, we further assume $\bar{a} \leq_X \bar{b}$, which we may write also as $(\bar{a},\bar{b}) \in \leq_X$. This implies with (3.240) in particular that there exist elements, say $\bar{\bar{a}}$ and $\bar{\bar{b}}$, satisfying the disjunction $\bar{\bar{a}} <_X \bar{\bar{b}} \vee \bar{\bar{a}} = \bar{\bar{b}}$ and $(\bar{\bar{a}},\bar{\bar{b}}) = (\bar{a},\bar{b})$. The latter equation now gives $\bar{\bar{a}} = \bar{a}$ and $\bar{\bar{b}} = \bar{b}$ with the Equality Criterion for ordered pairs, so that the preceding disjunction becomes $\bar{a} <_X \bar{b} \vee \bar{a} = \bar{b}$ after carrying out substitutions based on these equations. We thus proved the first part of the equivalence in (3.238).

To prove the second part ('$\Leftarrow$'), we now assume the disjunction $\bar{a} <_X \bar{b} \vee \bar{a} = \bar{b}$ to be true, so that the existential sentence

$$\exists a, b\,([a <_X b \vee a = b] \wedge (a,b) = (\bar{a},\bar{b}))$$

evidently holds. Furthermore, the initially assumed $\bar{a}, \bar{b} \in X$ implies $(\bar{a},\bar{b}) \in X \times X$ by definition of the Cartesian product of two sets. Together with the preceding existential sentence, this further implies $(\bar{a},\bar{b}) \in \leq_X$ according to (3.240), which finding we may then write also as $\bar{a} \leq_X \bar{b}$. This completes the proof of the equivalence and thus the proof of the implication in (3.238). Since $\bar{a}$ and $\bar{b}$ are arbitrary, we may therefore conclude that the universal sentence (3.238) holds.

Then, Proposition 3.80 applies also to the binary relation $\leq_X$, so that (3.235) holds as well.

Concerning c), we first verify that $\leq_X$ is reflexive, i.e. that $\leq_X$ satisfies

$$\forall a\,(a \in X \Rightarrow a \leq_X a). \tag{3.241}$$

For this purpose, we let a be arbitrary and assume $a \in X$. Because $a = a$ is obviously true, the disjunction $a <_X a \vee a = a$ holds then as well, so that $a \leq_X a$ follows to be true with (3.238). Since a is arbitrary, we may therefore conclude that the universal sentence (3.241) holds, which means indeed that $\leq_X$ is a reflexive binary relation on X.

To establish the antisymmetry of $\leq_X$, we verify accordingly

$$\forall a, b\,(a, b \in X \Rightarrow [(a \leq_X b \wedge b \leq_X a) \Rightarrow a = b]), \tag{3.242}$$

letting a and b be arbitrary in X, and assuming moreover $a \leq_X b$ and $b \leq_X a$ to hold. These assumptions imply with (3.238) the truth of the disjunctions $a <_X b \vee a = b$ and $b <_X a \vee b = a$. Thus, the conjunction of these two disjunctions holds, which we may write equivalently as

$$(a = b \vee a <_X b) \wedge (a = b \vee b <_X a),$$

applying the Commutative Law for the disjunction. We now obtain with the Distributive Law for sentences (1.45) the true disjunction

$$a = b \vee (a <_X b \wedge b <_X a). \tag{3.243}$$

Since $<_X$ is an irreflexive partial ordering, we may apply Exercise 3.26 to infer from $a, b \in X$ that the negation $\neg(a <_X b \wedge b <_X a)$ is true. Thus, the second part of the true disjunction (3.243) is false, and therefore the first part $a = b$ is true. We thus arrived at the desired consequent of the implication in (3.242) to be proven. The truth of this implication in turn established the truth of the implication based on the antecedent $a, b \in X$, and since a and b were arbitrary, we may therefore conclude that (3.242) is true, i.e. that $\leq_X$ is antisymmetric.

Finally, we prove the transitivity of $\leq_X$ by verifying the universal sentence

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [(a \leq_X b \wedge b \leq_X c) \Rightarrow a \leq_X c]). \tag{3.244}$$

Letting a, b, c be arbitrary in X, we further assume that $a \leq_X b$ and $b \leq_X c$ hold, so that we obtain the true conjunction

$$(a <_X b \vee a = b) \wedge (b <_X c \vee b = c)$$

by applying (3.238). Then, the Distributive Law for sentences (1.44) yields the true disjunction

$$[(a <_X b \vee a = b) \wedge b <_X c] \vee [(a <_X b \vee a = b) \wedge b = c]. \tag{3.245}$$

In case the first part of this disjunction is true, we have that the disjunction $a <_X b \vee a = b$ and $b <_X c$ are both true. On the one hand, if $a <_X b$ holds, the conjunction $a <_X b \wedge b <_X c$ is evidently true, which further implies $a <_X c$ with the transitivity if $<_X$. Then, the disjunction $a <_X c \vee a = c$ is also true (irrespective of the truth value of $a = c$), so that we obtain the desired $a \leq_X c$ with (3.238). On the other hand, if $a = b$ holds, then the previously established $b <_X c$ yields again $a <_X c$ (via substitution), so that the disjunction $a <_X c \vee a = c$ and therefore $a \leq_X c$ follow again to be true.

In case the second part of the disjunction (3.245) is true, we now see that the disjunction $a <_X b \vee a = b$ and $b = c$ are both true. On the one hand, if $a <_X b$ holds, then substitution based on the preceding equation yields $a <_X c$ and therefore the true disjunction $a <_X c \vee a = c$, so that the desired $a \leq_X c$ follows to true as shown before. On the other hand, if $a = b$ holds, then we obtain in view of $b = c$ the true equation $a = c$, so that the disjunction $a <_X c \vee a = c$ holds again (irrespective of the truth value of $a <_X c$). Thus, we obtain once again $a \leq_X c$, completing the proof of the implications in (3.244). As a, b and c are arbitrary, we may then infer from this that (3.244) holds, so that $\leq_X$ is also transitive.

We thus demonstrated that the binary relation $\leq_X$ on X is reflexive, antisymmetric and transitive, so that $\leq_X$ is a reflexive partial ordering of X, by definition. In the proofs of a) – c) the sets X and $<_X$ were arbitrary, so that the theorem holds, as claimed. $\square$

Note 3.9. The binary relation $\leq_X$ specified within the preceding theorem is thus compatible with Definition 3.20 of '$\leq$'.

Definition 3.22 (Induced reflexive partial ordering). For any set X and any irreflexive partial ordering $<_X$ of X we call the binary relation $\leq_X$ on X which satisfies

$$\forall a, b\,(a, b \in X \Rightarrow [a \leq_X b \Leftrightarrow (a <_X b \vee a = b)]) \tag{3.246}$$

the *reflexive partial ordering induced by* $<_X$.

Recalling that $\{(x, x)\}$ is a reflexive partial of ordering of a singleton $\{x\}$ according to Corollary 3.63 and that $\emptyset$ is an irreflexive partial ordering of $\{x\}$ due to Corollary 3.66, we now see that the preceding definition provides a direct link between the two partial orderings.

Proposition 3.82. *For any x it is true that the reflexive partial ordering $R = \{(x, x)\}$ of $X = \{x\}$ is identical with the reflexive partial ordering ($\leq_X$) induced by the irreflexive partial ordering $<_X = \emptyset$ of $\{x\}$.*

Proof. We let x be arbitrary and apply the Equality Criterion for sets to establish the identity of $R = \{(x, x)\}$ and the reflexive partial ordering $\leq_X$ induced by the irreflexive partial ordering $<_X = \emptyset$ of $X = \{x\}$. For this purpose, we verify

$$\forall Z\,(Z \in R \Leftrightarrow Z \in \leq_X), \tag{3.247}$$

letting Z be arbitrary. Let us first observe that $x \in X$ $[= \{x\}]$ holds according to (2.153). Now, to prove the first part ('$\Rightarrow$') of the equivalence, we assume $Z \in R$ $[= \{(x, x)\}]$ to be true, which implies $Z = (x, x)$ with (2.169). Then, the basic fact $x = x$ implies the truth of the disjunction $x <_X x \vee x = x$, so that (3.246) gives $x \leq_X x$. We may write this also as $[(x, x) =]\, Z \in \leq_X$, which finding completes the proof of the first part of the equivalence in (3.247).

To prove the second part ('$\Leftarrow$'), we now assume $Z \in \leq_X$ to be true. Since the (induced) reflexive partial ordering $\leq_X$ is by definition a binary relation on X, the equation $(\bar{a}, \bar{b}) = Z$ holds for particular constants $\bar{a}$ and $\bar{b}$, and $\leq_X$ is included in $X \times X$, i.e. included in $\{x\} \times \{x\}$. Consequently, $[Z =]\ (\bar{a}, \bar{b}) \in \leq_X$ implies $(\bar{a}, \bar{b}) \in \{x\} \times \{x\}$ with the definition of a subset. Since $\{x\} \times \{x\} = \{(x, x)\}$ holds due to (3.39), we therefore obtain $(\bar{a}, \bar{b}) \in \{(x, x)\}$ $[= R]$, so that the second part of the equivalence also holds. Since Z is arbitrary, we may now further conclude that (3.247) is true, so that the sets $\{(x, x)\}$ and $\leq_X$ are indeed equal. As x was also arbitrary, we may finally conclude that the proposition holds, as claimed. □

Theorem 3.83 (Induced total ordering). *For any set X and any linear ordering $<_X$ of X it is true that the induced reflexive partial ordering $\leq_X$ is a total ordering of X.*

Proof. Letting X and $<_X$ be arbitrary sets and assume that $<_X$ is a linear ordering of X. Let us first observe that $<_X$ is then more generally an irreflexive partial ordering of X, which induces the reflexive partial ordering $\leq_X$ of X. To show that $\leq_X$ is in the given situation also total, we now prove the universal sentence

$$\forall a, b\,(a, b \in X \Rightarrow [a \leq_X b \,\vee\, b \leq_X a]). \tag{3.248}$$

We let a and b be arbitrary and assume $a, b \in X$ to be true. Since the linear ordering $<_X$ is in particular connex, the multiple disjunction $a <_X b \vee b <_X a \vee a = b$ is true. If $a <_X b$ holds, then the disjunction $a <_X b \vee a = b$ is also true, which in turn implies $a \leq_X b$ with (3.238). Then, the desired disjunction $a \leq_X b \vee b \leq_X a$ also holds. Similarly, if the second part $b <_X a$ of the preceding multiple disjunction holds, then we obtain the true disjunction $b <_X a \vee b = a$, and therefore $b \leq_X a$ again with (3.238). Finally, if $a = b$ holds, then the previously considered disjunction $a <_X b \vee a = b$ is again true, with the consequence that $a \leq_X$ and then also $a \leq_X b \vee b \leq_X a$ hold, as shown earlier. Thus, the proof of the implication in (3.248) is complete, and since a and b are arbitrary, we may therefore conclude that the stated universal sentence is true. This means that the (induced) reflexive partial ordering $\leq_X$ is total and therefore, by definition, a total ordering of X. As X and $<_X$ were arbitrary, the theorem follows then to be true. □

Definition 3.23 (Induced total ordering). For any set X and any linear ordering $<_X$ of X we call the induced reflexive partial ordering $\leq_X$, which is total according to Theorem 3.83, the *total ordering induced by* $<_X$.

Proposition 3.84. *For any x and any y satisfying $x \neq y$ it is true that the total ordering $\leq_X$ induced by the linear ordering $<_X = \{(x, y)\}$ of the pair $X = \{x, y\}$ is identical with the triple $\{(x, x), (x, y), (y, y)\}$.*

Proof. We take arbitrary x and y and assume $x \neq y$ to be true, so that $<_X = \{(x, y)\}$ is indeed a linear ordering of $X = \{x, y\}$ due to Corollary 3.74. To prove that the triple $\{(x, x), (x, y), (y, y)\}$ is identical with the total ordering $\leq_X$ induced by $<_X$, we apply the Equality Criterion for sets and demonstrate accordingly the truth of

$$\forall Z\,(Z \in \{(x, x), (x, y), (y, y)\} \Leftrightarrow Z \in\, \leq_X). \tag{3.249}$$

To do this, we let Z be arbitrary and assume first $Z \in \{(x,x),(x,y),(y,y)\}$ to be true, so that

$$Z = (x,x) \lor Z = (x,y) \lor Z = (y,y) \tag{3.250}$$

holds according to (2.230). We now use this true disjunction to prove the sentence $Z \in \leq_X$ by cases. In the first case $Z = (x,x)$, we observe that the basic fact $x = x$ gives the true disjunction $x <_X x \lor x = x$. Then, since $x \in \{x,y\}$ is true in view of (2.151), the preceding disjunction implies $x \leq_X x$ with (3.238), which we may write also as $(x,x) \in \leq_X$. This in turn gives the desired consequent $Z \in \leq_X$ by means of substitution based on the current case assumption $Z = (x,x)$. In the second case $Z = (x,y)$, we notice that $(x,y) \in \{(x,y)\}$ $[= <_X]$ holds according to (2.153), so that we obtain $(x,y) \in <_X$, which we may write as $x <_X y$. Then, the disjunction $x <_X y \lor x = y$ is true as well, and since $x,y \in \{x,y\}$ holds with (2.151), this disjunction implies $x \leq_X y$ with (3.238). This means that $[Z =]$ $(x,y) \in \leq_X$ is true, so that $Z \in \leq_X$ holds also in the second case. Finally, in the third case $Z = (y,y)$, we see that $y = y$ yields the true disjunction $y <_X y \lor y = y$ where $y \in \{x,y\}$ holds (as mentioned within the proof for the second case), so that $y \leq_X y$ follows to be true with (3.238). Thus, we have $[Z =]$ $(y,y) \in \leq_X$, which shows that $Z \in \leq_X$ is true once again, so that the proof of that sentence by cases is complete. Therefore, the first part ('$\Rightarrow$') of the equivalence in (3.249) holds.

To prove the second part ('$\Leftarrow$'), we now assume conversely $Z \in \leq_X$ to be true. Because the induced total ordering $\leq_X$ is a binary relation on $X = \{x,y\}$, it is included in the Cartesian product $\{x,y\} \times \{x,y\}$, so that $Z \in \leq_X$ implies $Z \in \{x,y\} \times \{x,y\}$ with the definition of a subset. Moreover, there exist by definition of a binary relation two constants, say $\bar{a}$ and $\bar{b}$, such that $(\bar{a},\bar{b}) = Z$ holds. Then, $Z \in \{x,y\} \times \{x,y\}$ gives $(\bar{a},\bar{b}) \in \{x,y\} \times \{x,y\}$ via substitution, so that we obtain $\bar{a} \in \{x,y\}$ and $\bar{b} \in \{x,y\}$ with the definition of the Cartesian product of two sets. Furthermore, $Z \in \leq_X$ yields with the preceding equation $(\bar{a},\bar{b}) \in \leq_X$, which we may also write as $\bar{a} \leq_X \bar{b}$. Consequently, this inequality implies the disjunction $\bar{a} <_X \bar{b} \lor \bar{a} = \bar{b}$ with (3.238), which we may now use to prove the sentence $Z \in \{(x,x),(x,y),(y,y)\}$ by cases. In the first case that $\bar{a} <_X \bar{b}$ is true, we thus have $(\bar{a},\bar{b}) \in <_X$ $[= \{(x,y)\}]$, so that we obtain $[Z =]$ $(\bar{a},\bar{b}) = (x,y)$ with (2.169). Because of $Z = (x,y)$, the multiple disjunction (3.250) is then also true, which in turn implies the desired $Z \in \{(x,x),(x,y),(y,y)\}$ with (2.230). In the second case that $\bar{a} = \bar{b}$ is true, we see that $Z = (\bar{a},\bar{b})$ yields $Z = (\bar{a},\bar{a})$ by means substitution, where $\bar{a} \in \{x,y\}$ holds, as mentioned earlier. Therefore, the disjunction $\bar{a} = x \lor \bar{a} = y$ is true by definition of a pair, which we may now use to prove (3.250). by cases. On the one hand, if $\bar{a} = x$ holds, then the previously established $Z = (\bar{a},\bar{a})$ gives $Z = (x,x)$, and the disjunction (3.250) is then also true. On the other hand, if $\bar{a} = y$ holds, then $Z = (\bar{a}, \bar{a})$ yields $Z = (y, y)$, so that (3.250) is again true. Thus, the proof of that multiple disjunction by cases is complete, and this disjunction implies $Z \in \{(x,x),(x,y),(y,y)\}$ as in the first case. The truth of this sentence in turn proves the second part of the equivalence in (3.249).

As Z is arbitrary, we may therefore conclude that (3.249) is true, and we may now infer from this universal sentence the truth of the equality $\{(x,x),(x,y),(y,y)\} = \leq_X$. This shows that the total ordering $\leq_X$ induced by the linear ordering $<_X$ is indeed identical with $\{(x,x),(x,y),(y,y)\}$. Since x and y were initially arbitrary, we may finally conclude that the proposition is true. □

Corollary 3.85. *For any x and any y the ordered pair*

$$(\{x,y\}, \{(x,x),(x,y),(y,y)\}) \tag{3.251}$$

is a totally ordered set.

Proof. We let x and y be arbitrary and observe that the Law of the Excluded Middle yields the true disjunction $x = y \lor x \neq y$, which we now use to prove by cases that (3.251) is a totally ordered set. In the first case when $x = y$ is true, we obtain on the one hand the equation $\{x,y\} = \{x\}$ with (2.167). On the other hand, we evidently have that the two conjunctions $x = x \land y = x$ and $y = x \land y = x$ are true, which imply with the Equality Criterion for ordered pairs $(x,y) = (x,x)$ and $(y,y) = (x,x)$, respectively; these equations then imply together with (2.231)

$$\{(x,x),(x,y),(y,y)\} = \{(x,x),(x,x),(x,x)\} = \{(x,x)\}.$$

These findings show that the ordered pair (3.251) reduces in the current first case to the totally ordered set $(\{x\}, \{(x,x)\})$ established in Corollary 3.70. Regarding the other case $x \neq y$, we have that (3.251) is a totally ordered set because of Proposition 3.84. Since x and y were initially arbitrary, we may therefore conclude that the corollary is true. □

We may also begin with a reflexive partial ordering and induce a corresponding irreflexive partial ordering.

Theorem 3.86 (Characterization of induced irreflexive partial orderings). *The following sentences are true for any set X and any reflexive partial ordering $\leq_X$ of X.*

a) There exists a unique set $<_X$ such that an element Z is in $<_X$ iff Z is in $X \times X$ and moreover if there is an ordered pair (a,b) identical *with Z where a is less than or equal to b and simultaneously unequal to b, that is,*

$$\exists! <_X \forall Z \, (Z \in <_X \\ \Leftrightarrow [Z \in X \times X \, \wedge \, \exists a, b \, ([a \leq_X b \, \wedge \, a \neq b] \, \wedge \, (a, b) = Z)]).$$

b) *The set $<_X$ is a binary relation on X satisfying*

$$\forall a, b \, (a, b \in X \Rightarrow [a <_X b \; \Leftrightarrow \; (a \leq_X b \, \wedge \, a \neq b)]) \tag{3.252}$$

and moreover

$$\forall a, b \, (a, b \in X \Rightarrow [a \leq_X b \Leftrightarrow (a <_X b \, \vee \, a = b)]). \tag{3.253}$$

c) *The binary relation $<_X$ is an irreflexive partial ordering of X.*

Proof. We let X be an arbitrary set and $\leq_X$ an arbitrary reflexive partial ordering of X. We now evidently obtain the uniquely existential sentence a) with the Axiom of Specification in connection with the Equality Criterion for sets. Thus, the set $<_X$ satisfies

$$\forall Z \, (Z \in <_X \Leftrightarrow [Z \in X \times X \wedge \exists a, b \, ([a \leq_X b \wedge a \neq b] \wedge (a, b) = Z)]). \tag{3.254}$$

Concerning b), letting Z be arbitrary, we see that the assumption $Z \in <_X$ implies with (3.254) in particular $Z \in X \times X$, so that $<_X \subseteq X \times X$ follows to be true by definition of a subset. Thus, $<_X$ is a binary relation on X by definition.

Next, regarding (3.252), we let $\bar{a}$ and $\bar{b}$ be arbitrary and assume $\bar{a}, \bar{b} \in X$. To prove the first part ('$\Rightarrow$') of the equivalence, we further assume $\bar{a} <_X \bar{b}$, which we may write also as $(\bar{a}, \bar{b}) \in <_X$. This implies with (3.254) in particular that there exist elements, say $\bar{\bar{a}}$ and $\bar{\bar{b}}$, satisfying the conjunction $\bar{\bar{a}} \leq_X \bar{\bar{b}} \wedge \bar{\bar{a}} \neq \bar{\bar{b}}$ and $(\bar{\bar{a}}, \bar{\bar{b}}) = (\bar{a}, \bar{b})$. The latter equation now gives $\bar{\bar{a}} = \bar{a}$ and $\bar{\bar{b}} = \bar{b}$ with the Equality Criterion for ordered pairs, so that the preceding conjunction becomes $\bar{a} \leq_X \bar{b} \wedge \bar{a} \neq \bar{b}$ after carrying out substitutions based on these equations. We thus proved the first part of the equivalence in (3.252).

To prove the second part ('$\Leftarrow$'), we now assume the conjunction $\bar{a} \leq_X \bar{b} \wedge \bar{a} \neq \bar{b}$ to be true, so that the existential sentence

$$\exists a, b \, ([a \leq_X b \, \wedge \, a \neq b] \, \wedge \, (a, b) = (\bar{a}, \bar{b}))$$

evidently holds. Furthermore, the initially assumed $\bar{a}, \bar{b} \in X$ implies $(\bar{a}, \bar{b}) \in X \times X$ by definition of the Cartesian product of two sets. Together with the preceding existential sentence, this further implies $(\bar{a}, \bar{b}) \in <_X$ according to (3.254), which finding we may then write also as $\bar{a} <_X \bar{b}$. This completes the proof of the equivalence and thus the proof of the implication in (3.252). Since $\bar{a}$ and $\bar{b}$ are arbitrary, we may therefore conclude that the universal sentence (3.252) holds.

Regarding (3.253), we now let $\bar{a}$ and $\bar{b}$ be arbitrary and assume $\bar{a}, \bar{b} \in X$ to be true. To prove the first part ('$\Rightarrow$') of the equivalence by contradiction, we further assume $\bar{a} \leq_X \bar{b}$ and the negation $\neg(\bar{a} <_X \bar{b} \vee \bar{a} = \bar{b})$ to be true. The latter yields with De Morgan's Law for the disjunction the truth of $\neg \bar{a} <_X \bar{b}$ and of $\bar{a} \neq \bar{b}$. Here, we may write the former negation also as $\neg(\bar{a}, \bar{b}) \in <_X$, which negation in turn implies with (3.254) in connection with the Law of Contraposition and De Morgan's Law for the conjunction that $(\bar{a}, \bar{b}) \notin X \times X$ or

$$\neg \exists a, b \, (a \leq_X b \wedge a \neq b \wedge (a, b) = (\bar{a}, \bar{b}))$$

holds. Since the initial assumption $\bar{a}, \bar{b} \in X$ implies the truth of $(\bar{a}, \bar{b}) \in X \times X$ with the definition of the Cartesian product of two sets, the first part $(\bar{a}, \bar{b}) \notin X \times X$ of the preceding disjunction is false, so that the second part of that disjunction, i.e. the preceding negated existential sentence, is true. We may write the latter equivalently as

$$\forall a, b \, ((a, b) = (\bar{a}, \bar{b}) \Rightarrow \neg[a \leq_X b \wedge a \neq b])$$

by using the Quantifier Negation Law (1.54) in connection with the Commutative Law for the conjunction and (1.81). We may now infer from this for $\bar{a}$ and $\bar{b}$ that $\neg[\bar{a} \leq_X \bar{b} \wedge \bar{a} \neq \bar{b}]$ is true, in contradiction to the previously assumed/established truth of $\bar{a} \leq_X \bar{b}$ and $\bar{a} \neq \bar{b}$. Thus, the proof of the first part of the equivalence in (3.253) via contradiction is complete.

To prove the second part ('$\Leftarrow$'), we assume the disjunction $\bar{a} <_X \bar{b} \vee \bar{a} = \bar{b}$ to be true. In case of $\bar{a} <_X \bar{b}$, it follows with (3.254) in particular that there are elements, say $\bar{\bar{a}}$ and $\bar{\bar{b}}$, satisfying $\bar{\bar{a}} \leq_X \bar{\bar{b}}$, $\bar{\bar{a}} \neq \bar{\bar{b}}$ and $(\bar{\bar{a}}, \bar{\bar{b}}) = (\bar{a}, \bar{b})$. This equation gives with the Equality Criterion for ordered pairs $\bar{\bar{a}} = \bar{a}$ and $\bar{\bar{b}} = \bar{b}$, so that the previous finding $\bar{\bar{a}} \leq_X \bar{\bar{b}}$ yields the desired $\bar{a} \leq_X \bar{b}$ by substitution. In case the second part $\bar{a} = \bar{b}$ of the assumed disjunction holds, we see that the reflexivity of $\leq_X$ gives first $a \leq_X a$ and then again the desired $a \leq_X b$ via substitution based on the preceding equation. This completes the proof of the equivalence in (3.253), and since $\bar{a}$ and $\bar{b}$ were arbitrary, we may therefore conclude that the universal sentence (3.253) is true. As X and $\leq_X$ were initially arbitrary, this sentence is then true for any X and any $\leq_X$. $\square$

Exercise 3.31. Prove Theorem 3.86c).

Definition 3.24 (Induced irreflexive partial ordering). For any set X and any reflexive partial ordering $\leq_X$ of X we call the binary relation $<_X$ on X that satisfies

$$\forall a, b\,(a, b \in X \Rightarrow [a <_X b \Leftrightarrow (a \leq_X b \wedge a \neq b)]) \tag{3.255}$$

the *reflexive partial ordering induced by* $\leq_X$.

Example 3.1. The irreflexive partial ordering $<_{\mathcal{X}}$ induced by the reflexive partial ordering of inclusion '$\subseteq$' on a set system $\mathcal{X}$ satisfies

$$\begin{aligned}&\forall a, b\,(a, b \in X \Rightarrow [a <_X b \;\Leftrightarrow\; (a \subseteq b \wedge a \neq b)])\\ &\forall a, b\,(a, b \in X \Rightarrow [a \subseteq b \Leftrightarrow (a <_X b \vee a = b)])\end{aligned}$$

according to (3.252) and (3.253). Because of the definition of a proper subset and due to (2.26), these universal sentences evidently remain true if we replace $<_X$ by $\subset$. Thus, $\subset$ represents the irreflexive partial ordering of proper inclusion on a set system $\mathcal{X}$.

Proposition 3.87. *For any x it is true that the irreflexive partial ordering $R = \emptyset$ of $X = \{x\}$ is identical with the irreflexive partial ordering ($<_X$) induced by the reflexive partial ordering $\leq_X = \{(x, x)\}$ of $\{x\}$.*

Proof. We let x be arbitrary and apply the definition of the empty set to establish the identity of $R = \emptyset$ and of the irreflexive partial ordering $<_X$ induced by the reflexive partial ordering $\leq_X = \{(x, x)\}$ of $X = \{x\}$, by verifying

$$\forall Z\,(Z \notin\, <_X). \tag{3.256}$$

To do this, we let Z be arbitrary and show that assuming $Z \in\, <_X$ to be true implies a contradiction. As the (induced) irreflexive partial ordering $<_X$ is (by definition) a binary relation on X, we have $(\bar{a}, \bar{b}) = Z$ for particular constants $\bar{a}$ and $\bar{b}$, and $<_X$ is included in $X \times X$, that is, included in $\{x\} \times \{x\}$. With this, $[Z =]\ (\bar{a}, \bar{b}) \in\, <_X$ yields $(\bar{a}, \bar{b}) \in \{x\} \times \{x\}$ by definition of a subset, and therefore with the definition of the Cartesian product of two sets $\bar{a}, \bar{b} \in \{x\}$. The latter in turn implies $\bar{a} = x$ and $\bar{b} = x$ with (2.169), so that $(\bar{a}, \bar{b}) \in\, <_X$ gives $(x, x) \in\, <_X$ via substitution, which we may now write also as $x <_X x$. This inequality contradicts the fact that $\neg x <_X x$ is true because $<_X$ is irreflexive, and this finding completes the proof of $Z \notin\, <_X$ by contradiction. Since Z is arbitrary, we may therefore conclude that (3.256) holds, so that $<_X = \emptyset$ follows to be true (by definition of the empty set). Then, as x was also arbitrary, we may further conclude that the proposed universal sentence is true. □

Note 3.10. Proposition 3.82 and Proposition 3.87 show that the reflexive partial ordering $\{(x,x)\}$ of $\{x\}$ and the irreflexive partial ordering $\emptyset$ of $\{x\}$ induce each other.

The preceding note and the properties of an induced reflexive/irreflexive partial ordering suggest that there are pairs of partial orderings, consisting of a reflexive and an irreflexive partial ordering which correspond to each other in the sense that each of them uniquely determines the other one.

Proposition 3.88. *For any set X and any reflexive partial ordering $\leq_X$ of X, it is true that there exists a unique irreflexive partial ordering of X which induces $\leq_X$, and this inducing irreflexive partial ordering is identical with the irreflexive partial ordering $<_X$ of X induced by $\leq_X$.*

Proof. We let X and $\leq_X$ be arbitrary, assume that $\leq_X$ is a reflexive partial ordering of X, and denote by $<_X$ the irreflexive partial ordering of X induced by $\leq_X$. In a first step, we apply the Equality Criterion for sets to prove that the reflexive partial ordering $\leq'_X$ induced by $<_X$ is identical with the given $\leq_X$. For this purpose, we verify

$$\forall Z\,(Z \in\, \leq_X \Leftrightarrow\; Z \in\, \leq'_X). \tag{3.257}$$

We let Z be arbitrary and assume first $Z \in\, \leq_X$ to be true. As a partial ordering of X, we have that $\leq_X$ is a binary relation such that $\leq_X \subseteq X \times X$ holds. By definition of a binary relation, there are then constants, say $\bar{a}$ and $\bar{b}$, satisfying $(\bar{a},\bar{b}) = Z$. Therefore, $Z \in\, \leq_X$ yields by substitution $(\bar{a},\bar{b}) \in\, \leq_X$, which in turn gives with the preceding inclusion $(\bar{a},\bar{b}) \in X \times X$ (by definition of a subset). This further implies $\bar{a},\bar{b} \in X$ with the definition of the Cartesian product of two sets, and we may write $(\bar{a},\bar{b}) \in\, \leq_X$ as $\bar{a} \leq_X \bar{b}$. Since $<_X$ is induced by $\leq_X$, these findings imply in view of (3.253) the disjunction $\bar{a} <_X \bar{b} \vee \bar{a} = \bar{b}$, which in turn implies $\bar{a} \leq'_X \bar{b}$ because of (3.238) in connection with the fact that $\leq'_X$ is induced by $<_X$. Writing this inequality now as $[Z =]\ (\bar{a},\bar{b}) \in\, \leq'_X$, we see that the desired consequent $Z \in\, \leq'_X$ is true, so that the proof of the first part ('$\Rightarrow$') of the equivalence in (3.257) is complete.

To prove the second part ('$\Leftarrow$'), we now conversely assume $Z \in\, \leq'_X$ to be true. In analogy to the proof of the first part, there exist particular constants $\bar{a}$ and $\bar{b}$ such that $(\bar{a},\bar{b}) = Z$ holds. We thus have $(\bar{a},\bar{b}) \in\, \leq'_X$, which implies $(\bar{a},\bar{b}) \in X \times X$ since the partial ordering $\leq'_X$ is included in $X \times X$. We therefore obtain $\bar{a},\bar{b} \in X$ (by definition of the Cartesian product of two sets), and we may write for $(\bar{a},\bar{b}) \in\, \leq'_X$ also $\bar{a} \leq'_X \bar{b}$. Because $\leq'_X$ is induced by $<_X$, (3.238) gives $\bar{a} <_X \bar{b} \vee \bar{a} = \bar{b}$, which further implies $\bar{a} \leq_X \bar{b}$ with (3.253) – recalling that $<_X$ is induced by $\leq_X$. Since we may write the preceding inequality also as $[Z =]\ (\bar{a},\bar{b}) \in\, \leq_X$, the consequent $Z \in\, \leq_X$ of the implication '$\Leftarrow$' holds, as desired. Thus, the proof of the equivalence in (3.257) is complete, and since Z was arbitrary, we may therefore conclude that (3.257) is true.

Consequently, the reflexive partial orderings $\leq_X$ and $\leq'_X$ are indeed identical. Based on this equality, we may now apply substitution to the assumption that $<_X$ induces $\leq'_X$ to find that $<_X$ induces $\leq_X$. To show that there exists a unique irreflexive partial ordering of X which induces $\leq_X$, it therefore remains for us to demonstrate that $<_X$ is the only irreflexive partial ordering of X which induces $\leq_X$. To do this, we establish

$$\forall <'_X \, (<'_X \text{ is an irreflexive partial ordering of } X \text{ inducing } \leq_X \Rightarrow <_X = <'_X), \tag{3.258}$$

according to Method 1.18. We let $<'_X$ be an arbitrary set, assume that $<'_X$ is an irreflexive partial ordering of X such that $\leq_X$ is the reflexive partial ordering induced by $<'_X$, and show that $<_X$ and $<'_X$ follow to be identical sets. For this purpose, we verify

$$\forall Z \, (Z \in <_X \Leftrightarrow \; Z \in <'_X), \tag{3.259}$$

letting Z be arbitrary. To establish the first part ('$\Rightarrow$') of the equivalence, we may evidently follow the same line of arguments as in the proof of the first part of the equivalence in (3.257) to infer from the assumption $Z \in <_X$ the truth of $\bar{a} <_X \bar{b}$ for two particular elements $\bar{a}, \bar{b} \in X$ with $Z = (\bar{a}, \bar{b})$. Since $\leq_X$ is induced by $<_X$, we then obtain with (3.239) the true conjunction $\bar{a} \leq_X \bar{b} \wedge \bar{a} \neq \bar{b}$, which in turn implies $\bar{a} <'_X \bar{b}$ with (3.239) and the assumption that $\leq_X$ is also induced by $<'_X$. The preceding inequality shows that $[(\bar{a}, \bar{b}) =] \; Z \in <'_X$ holds, as desired.

We may establish the second part ('$\Leftarrow$') of the equivalence by applying similar arguments as in the proof of the second part of the equivalence in (3.257). Assuming $Z \in <'_X$ to be true, where $<'_X \subseteq X \times X$ holds, we obtain $\bar{a} <'_X \bar{b}$ holds for some particular constants $\bar{a}, \bar{b} \in X$ with $Z = (\bar{a}, \bar{b})$. As $\leq_X$ is induced by $<'_X$, this yields $\bar{a} \leq_X \bar{b} \wedge \bar{a} \neq \bar{b}$ with (3.239), which conjunction in turn gives $\bar{a} <_X \bar{b}$ again with (3.239) – recalling that $\leq_X$ is also induced by $<_X$. This inequality may be written as $[(\bar{a}, \bar{b}) =] \; Z \in <_X$, so that the second part of the equivalence also holds. As Z was arbitrary, we may therefore conclude that (3.259) is true, which completes the proof of the proposed uniquely existential sentence. We thus also showed that the irreflexive partial ordering $<_X$ (induced by $\leq_X$) induces itself $\leq_X$. $\square$

Exercise 3.32. Prove for any set X and any irreflexive partial ordering $<_X$ of X that there exists a unique reflexive partial ordering of X which induces $<_X$, and show furthermore that this inducing reflexive partial ordering is identical with the reflexive partial ordering $\leq_X$ of X induced by $<_X$.

(Hint: Proceed in analogy to the proof of Proposition 3.88.)

Theorem 3.89 (Induced linear ordering). *For any set X and any total ordering $\leq_X$ of X it is true that the induced irreflexive binary relation $<_X$ is a linear ordering of X.*

Proof. We let X and $\leq_X$ be arbitrary and assume that $\leq_X$ is a total ordering of X. Since $\leq_X$ is then a reflexive partial ordering of X, it induces the irreflexive partial ordering $<_X$. We now prove

$$\forall a, b\,(a, b \in X \Rightarrow [a <_X b \,\vee\, b <_X a \,\vee\, a = b]), \tag{3.260}$$

letting $\bar{a}$ and $\bar{b}$ be arbitrary in X. Thus, the ordered pairs $\bar{U} = (\bar{a}, \bar{b})$ and $\bar{V} = (\bar{b}, \bar{a})$ exist, where the first equation shows – together with $\bar{a} \in X$ and $\bar{b} \in X$ – that there are elements a and b with $a \in X$, $b \in X$ and $(a, b) = \bar{U}$, so that $\bar{U} \in X \times X$ follows to be true by definition of the Cartesian product of two sets. Similarly, the second equation equation shows – jointly with $\bar{b} \in X$ and $\bar{a} \in X$ – that there are elements b and a such that $b \in X$, $a \in X$ and $(b, a) = \bar{V}$ hold, with the consequence that $\bar{V} \in X \times X$. Furthermore, since $\leq_X$ is total, the disjunction $\bar{a} \leq_X \bar{b} \,\vee\, \bar{b} \leq_X \bar{a}$ is true.

In case that $\bar{a} \leq_X \bar{b}$ holds, we observe that the disjunction $\bar{a} \neq \bar{b} \vee \bar{a} = \bar{b}$ is also true, according to (1.10). On the one hand, if $\bar{a} \neq \bar{b}$ holds (alongside the current case assumption $\bar{a} \leq_X \bar{b}$), then we see that there exist a and b such that $a \leq_X b$, $a \neq b$ and $(a, b) = \bar{U}$ hold. Together with the previously established $\bar{U} \in X \times X$, this existential sentence implies $\bar{U} \in <_X$ with (3.254) and therefore $\bar{a} <_X \bar{b}$. Then, the disjunction

$$\bar{a} <_X \bar{b} \,\vee\, \bar{b} <_X \bar{a} \,\vee\, \bar{a} = \bar{b} \tag{3.261}$$

is evidently also true (irrespective of the truth values of $\bar{b} <_X \bar{a}$ and $\bar{a} = \bar{b}$). On the other hand, if $\bar{a} = \bar{b}$ holds, then the disjunction (3.261) follows immediately to be true (irrespective of the truth values of $\bar{a} <_X \bar{b}$ and $\bar{b} <_X \bar{a}$).

In case that $\bar{b} \leq_X \bar{a}$ is true, we may apply exactly the same arguments to infer from this the truth of the equivalence (3.261). To begin with, we notice that now $\bar{b} \neq \bar{a}$ or $\bar{b} = \bar{a}$ holds. On the one hand, if $\bar{b} \neq \bar{a}$ holds (alongside the current case assumption $\bar{b} \leq_X \bar{a}$), then there are evidently b and a satisfying $b \leq_X a$, $b \neq a$ and $(b, a) = \bar{V}$. Together with the previously established $\bar{V} \in X \times X$, this existential sentence yields $\bar{V} \in <_X$ and therefore $\bar{b} <_X \bar{a}$, proving the disjunction (3.261) irrespective of the truth values of $\bar{a} <_X \bar{b}$ and $\bar{a} = \bar{b}$. On the other hand, if $\bar{b} = \bar{a}$ holds, then evidently also $\bar{a} = \bar{b}$, and the disjunction (3.261) holds again.

We thus proved that $\bar{a}, \bar{b} \in X$ implies (3.261) in any case, and since $\bar{a}, \bar{b}$ are arbitrary, we may therefore conclude that the universal sentence

(3.260) is true. Thus, the irreflexive partial ordering $<_X$ is connex, too, and therefore a linear ordering of X by definition. Since X and $\leq_X$ were arbitrary, it follows that the theorem holds, as claimed. □

Exercise 3.33. Simplify the proof of Theorem 3.89 by using (3.252) and (3.253).

Definition 3.25 (Induced linear ordering). For any set X and any total ordering $\leq_X$ of X we call the induced irreflexive partial ordering $<_X$ (which is linear due to Theorem 3.89) the *linear ordering induced by* $\leq_X$.

Notation 3.3. In view of Exercise 3.32, we will use expressions such as

- "any partially ordered set $(X, <_X)$"
- "any linearly ordered set $(X, <_X)$"
- "any partially ordered set $(X, \leq_X)$"
- "any totally ordered set $(X, \leq_X)$"

in the sense that $<_X$ and $\leq_X$ are any sets such that, respectively,

- $<_X$ is an irreflexive partial and $\leq_X$ a reflexive partial ordering of X
- $<_X$ is a linear ordering and $\leq_X$ a total ordering of X
- $\leq_X$ is a reflexive partial and $<_X$ an irreflexive partial ordering of X
- $\leq_X$ is a total ordering and $<_X$ a linear ordering of X

where $<_X$ and $\leq_X$ induce each other.

3.3.3. Extremal elements

Aside from comparing elements of a partially/totally/linearly ordered set only relatively, it is in certain cases possible to also compare in an absolute sense with respect to certain 'extreme' elements.

Definition 3.26 (Maximal & minimal element). For any partially ordered set $(X, <_X)$ and any nonempty subset A of X,

(1) we say that an element $m \in A$ is a *maximal element* of A (with respect to $<_X$) iff no element of A is greater than m, i.e. iff

$$\forall x\, (x \in A \Rightarrow \neg m <_X x). \tag{3.262}$$

(2) we say that an element $m \in A$ is a *minimal* of A (with respect to $<_X$) iff no element of A is less than m, i.e. iff

$$\forall x\,(x \in A \Rightarrow \neg x <_X m). \tag{3.263}$$

Note 3.11. Due to (1.81), a maximal element m of A is equivalently characterized by

$$\neg\exists x\,(x \in A \wedge m <_X x), \tag{3.264}$$

and a minimal element m of A by

$$\neg\exists x\,(x \in A \wedge x <_X m). \tag{3.265}$$

It will also be useful to have a concept for a 'largest' element which need not necessarily lie in the considered set A.

Definition 3.27 (Upper & lower bound, bounded-from-above & bounded from below set). For any partially ordered set $(X, \leq_X)$ and any subset A of X,

(1) we say that an element $u \in X$ is an *upper bound* for A (with respect to $\leq_X$) iff every element of A is less than or equal to u, i.e. iff

$$\forall x\,(x \in A \Rightarrow x \leq_X u). \tag{3.266}$$

Furthermore, we say that A is *bounded from above* (with respect to $\leq_X$) iff there exists an upper bound for A (with respect to $\leq_X$), i.e. iff

$$\exists u\,(u \in X \wedge \forall x\,(x \in A \Rightarrow x \leq_X u)). \tag{3.267}$$

(2) we say that an element $a \in X$ is a *lower bound* for A (with respect to $\leq_X$) iff any element of A is greater than or equal to a, i.e. iff

$$\forall x\,(x \in A \Rightarrow a \leq_X x). \tag{3.268}$$

Moreover, we say that A is *bounded from below* (with respect to $\leq_X$) iff there exists a lower bound for A (with respect to $\leq_X$), i.e. iff

$$\exists a\,(a \in X \wedge \forall x\,(x \in A \Rightarrow a \leq_X x)). \tag{3.269}$$

(3) we say that A is *bounded* (with respect to $\leq_X$) iff A is both bounded from above and bounded from below (with respect to $\leq_X$).

Proposition 3.90. *For any partially ordered set $(X, \leq_X)$ it is true that any element of X is an upper bound for the empty set, i.e.*

$$\forall x\,(x \in X \Rightarrow \forall y\,(y \in \emptyset \Rightarrow y \leq_X x)). \tag{3.270}$$

Proof. We let X and $\leq_X$ be arbitrary and assume that $\leq_X$ is a reflexive partial ordering of X. Next, we let x be arbitrary and assume $x \in X$ to be true. Then, we take an arbitrary y and observe that $y \in \emptyset$ is false by definition of the empty set. Thus, the implication in (3.270) based on the false antecedent $y \in \emptyset$ is itself true. Since y is arbitrary, we may therefore conclude that the stated universal sentence with respect to y is true, which in turn proves the implication based on the antecedent $x \in X$. Because x is also arbitrary, we may now further conclude that the universal sentence (3.270) holds. Finally, as X and $\leq_X$ were initially arbitrary, the proposed sentence follows then to be true. □

Exercise 3.34. Verify for any partially ordered set $(X, \leq_X)$ that every element of X is a lower bound for the empty set, i.e.

$$\forall x\,(x \in X \Rightarrow \forall y\,(y \in \emptyset \Rightarrow x \leq_X y)). \tag{3.271}$$

Proposition 3.91. *For any partially ordered set $(X, \leq_X)$ and any element $y \in X$, it is true that the singleton formed by y is bounded from above by y.*

Proof. We let X, $\leq_X$ and y be arbitrary, assume that $\leq_X$ is a reflexive partial ordering of X, and assume moreover that $y \in X$ is true. Therefore, the singleton $\{y\}$ is a subset of X according to (2.184). To show that y is an upper bound for $\{y\}$, we now verify

$$\forall x\,(x \in \{y\} \Rightarrow x \leq_X y). \tag{3.272}$$

To do this, we let x be arbitrary and assume $x \in \{y\}$ to be true, which implies $x = y$ with (2.169). As we initially assumed $\leq_X$ to be reflexive, $x \leq_X x$ is true, so that substitution based on the preceding equation gives $x \leq_X y$, which proves the implication in (3.272). Since x is arbitrary, we may therefore conclude that the universal sentence (3.272) is true, so that y is by definition an upper bound for $\{y\}$. As X, $\leq_X$ and y were arbitrary, the proposed universal sentence follows then to be true. □

Exercise 3.35. Show for any partially ordered set $(X, \leq_X)$ and any $y \in X$ that the singleton formed by y is bounded from below by y.

Theorem 3.92 (Characterization of upper & lower bounds for pairs). *For any partially ordered set $(X, \leq_X)$ and any y, z it is true that*

a) an element $u \in X$ is an upper bound for the pair $\{y, z\}$ iff

$$y \leq_X u \wedge z \leq_X u. \tag{3.273}$$

b) an element $a \in X$ is a lower bound for the pair $\{y, z\}$ iff

$$a \leq_X y \wedge a \leq_X z. \tag{3.274}$$

Proof. We let X, $\leq_X$, y and z be arbitrary, assume $\leq_X$ to be a reflexive partial ordering of X, and assume $y, z \in X$ to be true, so that $\{y, z\} \subseteq X$ holds according to (2.164). Concerning a), we let u be arbitrary and assume that $u \in X$ holds. Next, we assume that u is an upper bound for $\{y, z\}$, so that

$$\forall x \, (x \in \{y, z\} \Rightarrow x \leq_X u) \tag{3.275}$$

holds. According to (2.151), $y \in \{y, z\}$ and $z \in \{y, z\}$ are both true, so that (3.275) gives $y \leq_X u$ and $z \leq_X u$, and therefore the conjunction (3.273) holds.

Conversely, we now assume this conjunction $y \leq_X u \wedge z \leq_X u$ to be true, and we now show that this implies the truth of the universal sentence (3.275). Letting x be arbitrary and assuming $x \in \{y, z\}$ to be true, it follows by definition of a pair that the disjunction $x = y \vee x = z$ holds. If $x = y$ is true, then the assumed $y \leq_X u$ yields $x \leq_X u$ via substitution, and if $x = z$ holds, then the assumed $z \leq_X u$ gives $x \leq_X u$ again. Therefore, the implication in (3.275) is true, and as x is arbitrary, we may infer from this that (3.275) holds. Consequently, u is by definition an upper bound for $\{y, z\}$, and the proof of the stated equivalence is complete. Since u is arbitrary, we may then further conclude that a) is true. This is then true for any X, any $\leq_X$, and any a, b. □

Exercise 3.36. Prove Theorem 3.92b).

The preceding characterization extends in a natural way to triples.

Theorem 3.93 (Characterization of upper & lower bounds for triples). *For any partially ordered set $(X, \leq_X)$ and any $w, y, z \in X$ it is true that*

a) an element $u \in X$ is an upper bound for the triple $\{w, y, z\}$ iff

$$w \leq_X u \wedge y \leq_X u \wedge z \leq_X u. \tag{3.276}$$

b) an element $a \in X$ is a lower bound for the pair $\{y, z\}$ iff

$$a \leq_X w \wedge a \leq_X y \wedge a \leq_X z. \tag{3.277}$$

Exercise 3.37. Prove Theorem 3.93.

(Hint: Proceed in analogy to the proof of Theorem 3.92.)

Proposition 3.94. *For any partially ordered set $(X, \leq_X)$ and any bounded-from-above subset A of X (with respect to $\leq_X$) it is true that any subset B of A is itself bounded from above (with respect to $\leq_X$), having the same upper bound as A.*

Proof. We let X and $\leq_X$ be arbitrary sets such that $\leq_X$ is a reflexive partial ordering of X, let A an arbitrary bounded-from-above subset of X, and let B an arbitrary subset of A. Since A is bounded from above, there exists an element of X, say $\bar{u}$, such that

$$\forall x\,(x \in A \Rightarrow x \leq_X \bar{u}). \tag{3.278}$$

We now show that $\bar{u}$ is also an upper bound for B, i.e.

$$\forall x\,(x \in B \Rightarrow x \leq_X \bar{u}). \tag{3.279}$$

For this purpose, we let x be arbitrary in B, which implies $x \in A$ due to the assumption $B \subseteq A$ (applying the definition of a subset). Then, $x \in A$ implies in turn $x \leq_X \bar{u}$ with (3.278), which proves the implication in (3.279). As x is arbitrary, we therefore conclude that the universal sentence (3.279) holds, so that the existential sentence

$$\exists u\,(u \in X \;\wedge\; \forall x\,(x \in B \Rightarrow x \leq_X u))$$

is true. Thus, the set B is bounded from above by definition. Since X, $\leq_X$, A and B were also arbitrary, it follows that the proposition holds, as claimed. □

Exercise 3.38. Show for any partially ordered set $(X, \leq_X)$ and any bounded-from-below subset A of X that any subset B of A is itself bounded from below, having the same lower bound as A.

We now consider the particular subset $X \subseteq X$ in place of A.

Proposition 3.95. *For any partially ordered set $(X, \leq_X)$ and any subset A of X, it is true that, if there exists an upper bound for A in A, then it exists uniquely, i.e.*

$$\exists u\,(u \in A \wedge \forall x\,(x \in A \Rightarrow x \leq_X u)) \Rightarrow \exists! u\,(u \in A \wedge \forall x\,(x \in A \Rightarrow x \leq_X u)). \tag{3.280}$$

Proof. We let X, $\leq_X$ and A be arbitrary sets, assume that $\leq_X$ is a reflexive partial ordering of X and that A is a subset of X, and we further assume that there exists an upper bound for A in A. Thus, the existential part of the uniquely existential sentence to be proven holds already by assumption. To establish the truth of the uniqueness part, we verify

$$\forall u, u' \, ([u \in A \, \wedge \, \forall x \, (x \in A \Rightarrow x \leq_X u) \, \wedge \, u' \in A \, \wedge \, \forall x \, (x \in A \Rightarrow x \leq_X u')] \\ \Rightarrow u = u'). \tag{3.281}$$

For this purpose, we let u and u' be arbitrary, assume $u, u' \in A$, and assume further that the universal sentences

$$\forall x \, (x \in A \Rightarrow x \leq_X u) \tag{3.282}$$

$$\forall x \, (x \in A \Rightarrow x \leq_X u') \tag{3.283}$$

hold. Then, the assumed $u' \in A$ implies $u' \leq_X u$ with (3.282), and similarly the assumed $u \in A$ implies $u \leq_X u'$ with (3.283). As the reflexive partial ordering $\leq$ is by definition antisymmetric, the conjunction $u' \leq_X u \wedge u \leq_X u'$ implies then the desired $u = u'$, so that the proof of the implication in (3.281) is complete. Since u and u' are arbitrary, we may therefore conclude that (3.281) and thus the uniqueness part of the uniquely existential sentence to be proven also hold. This completes the proof of the implication (3.280); as X, $\leq_X$ and A were arbitrary, we may therefore conclude that the proposition is true. □

Exercise 3.39. Show for any partially ordered set $(X, \leq_X)$ and any $A \subseteq X$ that, if there exists a lower bound for A, then it exists uniquely, i.e.

$$\exists a \, (a \in A \wedge \forall x \, (x \in A \Rightarrow a \leq_X x)) \Rightarrow \exists! a \, (a \in A \wedge \forall x \, (x \in A \Rightarrow a \leq_X x)). \tag{3.284}$$

Definition 3.28 (Maximum/greatest/top & minimum/least/bottom element). For any partially ordered set $(X, \leq_X)$ and any subset A of X,

(1) we say that an element $u \in X$ is the *maximum element* or the *greatest element* or the *top element* (with respect to $\leq_X$), symbolically

$$u = \overset{\leq_X}{\max} A = \max A, \tag{3.285}$$

iff u is an upper bound for A (with respect to $\leq_X$) contained in A, i.e. iff

$$\forall x \, (x \in A \Rightarrow x \leq_X u) \, \wedge \, u \in A. \tag{3.286}$$

(2) we say that an element $a \in X$ is the *minimum element* or the *least element* or the *bottom element* (with respect to $\leq_X$), symbolically

$$a = \overset{\leq_X}{\min} A = \min A, \tag{3.287}$$

iff a is a lower bound for A (with respect to $\leq_X$) contained in A, i.e. iff

$$\forall x\,(x \in A \Rightarrow a \leq_X x) \wedge a \in A. \tag{3.288}$$

Corollary 3.96. *For any partially ordered set* $(X, \leq_X)$ *and any element* y *in* X *it is true that* y *is the maximum and the minimum of the singleton formed by* y*, i.e.*

$$\forall y\,(y \in X \Rightarrow y = \max\{y\} = \min\{y\}). \tag{3.289}$$

Proof. We let X, $\leq_X$ and y be arbitrary, assume $\leq_X$ to be a reflexive partial ordering of X, and moreover we assume $y \in X$ to be true. Then, y is both an upper and a lower bound for $\{y\}$ according to Proposition 3.91 and Exercise 3.35. Since $y \in \{y\}$ is evidently true as well, it follows that y is the maximum and also the minimum of $\{y\}$. As y is arbitrary, we may therefore conclude that (3.289) holds, and since X and $\leq_X$ were also arbitrary, it follows that the corollary is true. □

Maximal and maximum elements coincide in case of total/linear orderings.

Proposition 3.97. *For any linearly ordered set* $(X, <_X)$ *and any subset* A *of* X*, it is true that an element* $m \in A$ *is a maximal element of* A *iff* m *is the maximum element of* A*.*

Proof. We let X, $<_X$ and $\leq_X$ be arbitrary sets such that $<_X$ is a linear and $\leq_X$ a total ordering of X inducing each other. Moreover, we let A be an arbitrary subset of X and m an arbitrary element of A. To prove the first implication '⇒', we assume that m is a maximal element of A so that

$$\forall x\,(x \in A \Rightarrow \neg m <_X x) \tag{3.290}$$

holds. To show that m is then the maximum elements, i.e. an upper bound for A (in A), we verify

$$\forall x\,(x \in A \Rightarrow x \leq_X m). \tag{3.291}$$

To do this, we let x be arbitrary and assume $x \in A$, which implies $\neg m <_X x$ with (3.290). The latter further implies $m \geq_X x$ with the Negation Formula for $<$, so that the desired consequent $x \leq_X m$ in (3.291) is true. Since x is arbitrary, we may therefore conclude that the universal sentence (3.291) holds, which means that m is indeed the maximum element of A.

Conversely, to prove the second implication '⇐', we now assume that m is the maximum element of X, so that the universal sentence (3.291) is by definition true. To prove that m follows to be also a maximal element of A, we demonstrate the truth of (3.290). For this purpose, we let $x \in A$ be arbitrary, so that $x \leq_X m$ and therefore $m \geq_X x$ is true. The latter implies now $\neg m <_X x$ with the Negation Formula for $<$, so that the the implication in (3.290) holds. As x was arbitrary, we may infer from this the truth of the universal sentence (3.290). Thus, m is by definition a maximal element of A. Since X and $<_X/\leq_X$ were arbitrary, we may finally conclude that the proposition is true. $\square$

Exercise 3.40. Show for any linearly ordered set $(X, <_X)$ and any subset A of X that an element m of A is a minimal element of A iff m is the minimum element of A.

A special case of a linearly ordered set is one for which all subsets have a least element.

Definition 3.29 (Well-ordering, well-ordered set). For any totally ordered set $(X, \leq_X)$ we say that $\leq_X$ is a *well-ordering* of X iff every nonempty subset of X has a least element, that is, iff

$$\forall A\,([A \subseteq X \;\wedge\; A \neq \emptyset] \Rightarrow \exists m\,(m \in A \;\wedge\; \forall x\,(x \in A \Rightarrow m \leq_X x))). \quad (3.292)$$

We then call $(X, \leq_X)$ a *well-ordered set*.

The notions of a 'least upper bound' and of a 'greatest lower bound' will be of great practical relevance. define these concepts after the following preparatory exercise.

Exercise 3.41. Verify the following sentences for any partially ordered set $(X, \leq_X)$ and any subset A of X.

a) There exists a unique set U consisting of all the upper bounds for A (with respect to $\leq_X$), in the sense that

$$\forall u\,(u \in U \Leftrightarrow \forall x\,(x \in A \Rightarrow x \leq_X u)). \quad (3.293)$$

b) There exists a unique set L consisting of all the lower bounds for A (with respect to $\leq_X$), in the sense that

$$\forall a\,(a \in L \Leftrightarrow \forall x\,(x \in A \Rightarrow a \leq_X x)). \quad (3.294)$$

(Hint: Apply Axiom 2.2 in connection with Theorem 2.6, recalling that any upper/lower bound for A is by definition an element of X.)

Definition 3.30 (Supremum/least upper bound, infimum/greatest lower bound). For any partially ordered set $(X, \leq_X)$, for any subset A of X, and

(1) for any S, we say that S is the *supremum* or the *least upper bound* of A (with respect to $\leq_X$), symbolically

$$S = \overset{\leq}{\sup} A = \sup A, \tag{3.295}$$

iff S is the least element of the set U consisting of all upper bounds for A (with respect to $\leq_X$).

(2) for any I, we say that I is the *infimum* or the *greatest lower bound* of A (with respect to $\leq_X$), symbolically

$$I = \overset{\leq}{\inf} A = \inf A, \tag{3.296}$$

iff I is the greatest element of the set L consisting of all lower bounds for A (with respect to $\leq_X$).

Theorem 3.98 (Characterization of suprema & infima). *For any partially ordered set $(X, \leq_X)$ and any subset A of X, it is true*

a) for any S that S is the supremum of A (with respect to $\leq_X$) iff S is an upper bound for A and moreover if S is less than or equal to any upper bound S' for A, i.e. iff

$$\forall x\,(x \in A \Rightarrow x \leq_X S) \wedge \forall S'\,(\forall x\,(x \in A \Rightarrow x \leq_X S') \Rightarrow S \leq_X S'). \tag{3.297}$$

b) for any I that I is the infimum of A (with respect to $\leq_X$) iff I is a lower bound for A and moreover if I is greater than or equal to any lower bound I' for A, i.e. iff

$$\forall x\,(x \in A \Rightarrow I \leq_X x) \wedge \forall I'\,(\forall x\,(x \in A \Rightarrow I' \leq_X x) \Rightarrow I' \leq_X I). \tag{3.298}$$

Proof. We let X be an arbitrary set, $\leq_X$ an arbitrary reflexive partial ordering of X, and A an arbitrary subset of X. Concerning a), we let S be arbitrary and prove the first part ('$\Rightarrow$') of the proposed equivalence directly, assuming that S is the supremum of A, so that S is by definition the least element of the set U consisting of all upper bounds for A. By definition of a least element, we thus have that S is a lower bound for U contained in U, i.e.

$$\forall S'\,(S' \in U \Rightarrow S \leq_X S') \wedge S \in U. \tag{3.299}$$

Here, $S \in U$ implies with (3.293) that S is an upper bound for A, i.e.

$$\forall x \, (x \in A \Rightarrow x \leq_X S), \tag{3.300}$$

so that the first part of the conjunction (3.297) to be proven holds (for the given S). We now verify the second part

$$\forall S' \, (\forall x \, (x \in A \Rightarrow x \leq_X S') \Rightarrow S \leq_X S'). \tag{3.301}$$

To do this, we let $\bar{S}'$ be arbitrary and assume

$$\forall x \, (x \in A \Rightarrow x \leq_X \bar{S}') \tag{3.302}$$

to be true, which conjunction implies $\bar{S}' \in U$ with (3.293) and then $S \leq_X \bar{S}'$ with the first part of the conjunction (3.299). This proves the implication in (3.301), and since $\bar{S}'$ is arbitrary, we may therefore conclude that the universal sentence (3.301) is true. Thus, the proof of the conjunction 3.297) (for the given S) is complete, so that the first part of the proposed equivalence holds.

To prove the second part ('$\Leftarrow$'), we now assume that S satisfies (3.297) and show that S is the supremum of A, i.e. that S is the least element of the set U, i.e. that S satisfies (3.299). Regarding the first part of that conjunction, we let $\bar{S}'$ be arbitrary and assume that $\bar{S}' \in U$ holds, which assumption implies (3.302) with the specification of U, i.e. that $\bar{S}'$ is an upper bound for A. This further implies with the second part of the assumed conjunction (3.297) that $S \leq_X \bar{S}'$ holds. Therefore, $\bar{S}'$ satisfies indeed the first part of the conjunction (3.299). Furthermore, the first part of the assumed conjunction (3.297) implies $S \in U$ by definition of U, so that the second part of the conjunction (3.299) also holds. This means that S is the supremum of A, completing the proof of the stated equivalence. Since S is arbitrary, we may therefore conclude that a) holds.

As X, $\leq_X$ and A were also arbitrary, we may further conclude that a) is true for any X, and $\leq_X$ and any A. □

Exercise 3.42. Prove Part b) of Theorem 3.98.

Note 3.12. If S is the supremum of a subset A of a set X, then we have $S \in X$ since upper bounds of $A \subseteq X$ are by definition elements of X. Similarly, if I is the infimum of $A \subseteq X$, then we have $I \in X$ because lower bounds of $A \subseteq X$ are by definition elements of X.

We will frequently encounter sets that are 'closed' under the formation of suprema and infima in the following sense.

Definition 3.31 (Lattice, complete lattice). For any nonempty set X we say that

(1) a partially ordered set $(X, \leq_X)$ is a *lattice* iff every pair $\{x, y\}$ of elements in X has both a supremum and an infimum with respect to $\leq_X$, i.e. iff

$$\forall x, y\, (x, y \in X \Rightarrow \exists S, I\, (S, I \in X \,\wedge\, S = \overset{\leq_X}{\sup}\{x, y\} \,\wedge\, I = \overset{\leq_X}{\inf}\{x, y\})). \tag{3.303}$$

(2) a partially ordered set $(X, \leq_X)$ is a *complete lattice* iff every subset A of X has both a supremum and an infimum with respect to $\leq_X$, i.e. iff

$$\forall A\, (A \subseteq X \Rightarrow \exists S, I\, (S, I \in X \,\wedge\, S = \overset{\leq_X}{\sup} A \,\wedge\, I = \overset{\leq_X}{\inf} A)). \tag{3.304}$$

Corollary 3.99. *It is true that any complete lattice $(X, \leq_X)$ is a lattice.*

Proof. Letting X and $\leq_X$ be arbitrary sets, assuming X to be nonempty and $\leq_X$ to be a reflexive partial ordering of X such that the ordered pair $(X, \leq_X)$ is a complete lattice, we take arbitrary constants $x, y \in X$, so that $\{x, y\} \subseteq X$ holds according to (2.164). Since $(X, \leq_X)$ is a complete lattice, there exist then elements of X, say $\bar{S}$ and $\bar{I}$, which are respectively the supremum $\bar{S} = \sup^{\leq_X}\{x, y\}$ and the infimum $\bar{S} = \sup^{\leq_X}\{x, y\}$ of the pair. As x and y are arbitrary, we may therefore conclude that the $(X, \leq_X)$ is a lattice, by definition. Because X was initially arbitrary, we may then infer from this finding the truth of the stated universal sentence. $\square$

To shed some light on the lattice concept, we develop in the following a first simple example of a complete lattice.

Proposition 3.100. *For any set X, it is true that*

a) the intersection of any subset $\mathcal{K}$ of the power set of X is identical with the infimum of $\mathcal{K}$, i.e.

$$\forall \mathcal{K}\, (\mathcal{K} \subseteq \mathcal{P}(X) \Rightarrow \bigcap \mathcal{K} = \inf \mathcal{K}), \tag{3.305}$$

b) the union of any subset $\mathcal{K}$ of the power set of X is identical with the supremum of $\mathcal{K}$, i.e.

$$\forall \mathcal{K}\, (\mathcal{K} \subseteq \mathcal{P}(X) \Rightarrow \bigcup \mathcal{K} = \sup \mathcal{K}), \tag{3.306}$$

where the infimum and the supremum are taken with respect to the reflexive partial ordering of inclusion of $\mathcal{P}(X)$.

Proof. We let X be an arbitrary set. Concerning a), we let $\mathcal{K}$ also be an arbitrary set and assume moreover $\mathcal{K} \subseteq \mathcal{P}(X)$ to be true. Since the universal sentence $\forall A\,(A \in \mathcal{K} \Rightarrow \bigcap \mathcal{K} \subseteq A)$ holds in view of (2.92), we evidently obtain with the specification of a reflexive partial ordering of inclusion

$$\forall A\,(A \in \mathcal{K} \Rightarrow \bigcap \mathcal{K} \subseteq_{\mathcal{P}(\Omega)} A), \tag{3.307}$$

so that $\bigcap \mathcal{K}$ is a lower bound for $\mathcal{K}$ (with respect to $\subseteq_{\mathcal{P}(\Omega)}$). According to the Characterization of the infimum, it therefore remains for us to prove

$$\forall L\,(\forall A\,(A \in \mathcal{K} \Rightarrow L \subseteq_{\mathcal{P}(\Omega)} A) \Rightarrow L \subseteq_{\mathcal{P}(\Omega)} \bigcap \mathcal{K}) \tag{3.308}$$

To do this, we take an arbitrary set L, assume

$$\forall A\,(A \in \mathcal{K} \Rightarrow L \subseteq_{\mathcal{P}(\Omega)} A) \tag{3.309}$$

(i.e., that L is a lower bound for $\mathcal{K}$ in $\mathcal{P}(X)$), and we show that $L \subseteq_{\mathcal{P}(\Omega)} \bigcap \mathcal{K}$ follows to be true, which we may write equivalently as $L \subseteq \bigcap \mathcal{K}$. For this purpose, we verify (according to the definition of a subset)

$$\forall y\,(y \in L \Rightarrow y \in \bigcap \mathcal{K}), \tag{3.310}$$

letting $\bar{y}$ be arbitrary and assuming $\bar{y} \in L$ to be true. To establish the desired consequent $\bar{y} \in \bigcap \mathcal{K}$, we apply the definition of the intersection of a set system and prove the universal sentence

$$\forall A\,(A \in \mathcal{K} \Rightarrow \bar{y} \in A). \tag{3.311}$$

We take an arbitrary set $\bar{A}$ and assume that $\bar{A} \in \mathcal{K}$ holds, which implies $L \subseteq_{\mathcal{P}(\Omega)} \bar{A}$ with (3.309), which we may write as $L \subseteq \bar{A}$ and therefore (by definition of a subset)

$$\forall y\,(y \in L \Rightarrow y \in \bar{A}).$$

With this, the previously made assumption $\bar{y} \in L$ yields $\bar{y} \in \bar{A}$, proving the implication in (3.311). Since $\bar{A}$ is arbitrary, we may therefore conclude that (3.311) is true, which universal sentence then implies the truth of $\bar{y} \in \bigcap \mathcal{K}$ (by definition of the intersection of a set system). This finding in turn proves the implication in (3.310), and as $\bar{y}$ was arbitrary, we may infer from this the truth of the universal sentence (3.310), which then gives $L \subseteq \bigcap \mathcal{K}$ (by definition of a subset), and equivalently $L \subseteq_{\mathcal{P}(\Omega)} \bigcap \mathcal{K}$. Thus, the proof of the implication in (3.308) is complete, and because L was arbitrary, we may now further conclude that the universal sentence (3.308) is true as well. The conjunction of (3.307) and (3.308) finally shows (in light of the Characterization of the infimum) that $\bigcap \mathcal{K}$ is the greatest lower bound for $\mathcal{K}$ in $\mathcal{P}(X)$. Since X was initially an arbitrary set, Part a) of the proposition follows to be true. □

Exercise 3.43. Establish Part b) of Proposition 3.100.

(Hint: Simply apply the definition of the union of a set system in place of the definition of the intersection of a set system.)

Recalling that the power set of any set X is nonempty in view of (3.15) and observing in light of the preceding proposition and exercise that the infimum and the supremum of any subset of a power set $\mathcal{P}(X)$ exist, we may immediately apply the definition of a complete lattice to power sets that are partially ordered by inclusion.

Corollary 3.101. *The ordered pair $(\mathcal{P}(X), \subseteq_{\mathcal{P}(X)})$ formed by the power set of any set X and the reflexive partial ordering of inclusion on $\mathcal{P}(X)$ is a complete lattice.*

Proposition 3.102. *For any set X, any subset $\mathcal{Y} \subseteq \mathcal{P}(X)$, any subset $\mathcal{K} \subseteq \mathcal{Y}$ and any set $I \in \mathcal{Y}$, it is true that I is the intersection of $\mathcal{K}$ iff I is the infimum of $\mathcal{K}$ with respect to $\subseteq_{\mathcal{Y}}$, i.e.*

$$I = \bigcap \mathcal{K} \;\Leftrightarrow\; I = \overset{\subseteq_{\mathcal{Y}}}{\inf} \mathcal{K}. \tag{3.312}$$

Proof. We let X, $\mathcal{Y}$, $\mathcal{K}$ and I be arbitrary sets and assume $\mathcal{Y} \subseteq \mathcal{P}(X)$, $\mathcal{K} \subseteq \mathcal{Y}$ as well as $I \in \mathcal{Y}$ to be true. Let us observe here that the assumed inclusions give $\mathcal{K} \subseteq \mathcal{P}(X)$ with (2.13), which implies with Proposition 3.100a) the equation

$$\bigcap \mathcal{K} = \overset{\subseteq_{\mathcal{P}(X)}}{\inf} \mathcal{K}. \tag{3.313}$$

To prove now the first part ('⇒') of the equivalence (3.312), we assume $I = \bigcap \mathcal{K}$ to be true, so that (3.313) gives

$$I = \overset{\subseteq_{\mathcal{P}(X)}}{\inf} \mathcal{K}, \tag{3.314}$$

which we may write also as

$$\forall A\,(A \in \mathcal{K} \Rightarrow I \subseteq_{\mathcal{P}(X)} A) \wedge \forall I'\,(\forall A\,(A \in \mathcal{K} \Rightarrow I' \subseteq_{\mathcal{P}(X)} A) \Rightarrow I' \subseteq_{\mathcal{P}(X)} I), \tag{3.315}$$

according to the Characterization of the infimum. For the same reason, the desired consequent

$$I = \overset{\subseteq_{\mathcal{Y}}}{\inf} \mathcal{K} \tag{3.316}$$

can be written equivalently as

$$\forall A\,(A \in \mathcal{K} \Rightarrow I \subseteq_{\mathcal{Y}} A) \wedge \forall I'\,(\forall A\,(A \in \mathcal{K} \Rightarrow I' \subseteq_{\mathcal{Y}} A) \Rightarrow I' \subseteq_{\mathcal{Y}} I). \tag{3.317}$$

To show that the first part

$$\forall A\,(A \in \mathcal{K} \Rightarrow I' \subseteq_{\mathcal{Y}} A) \tag{3.318}$$

of this conjunction holds, we take an arbitrary set A and assume $A \in \mathcal{K}$ to be true, which implies with the first part of the conjunction (3.315) that $I \subseteq_{\mathcal{P}(X)} A$. Due to the specification of the reflexive partial ordering of inclusion, we may write this first as $I \subseteq A$, and then also as $I \subseteq_{\mathcal{Y}} A$. Since A is arbitrary, we may therefore conclude that the first part of the conjunction (3.317) is true. To establish the second part, we take an arbitrary set I', assume the universal sentence

$$\forall A\,(A \in \mathcal{K} \Rightarrow I' \subseteq_{\mathcal{Y}} A) \tag{3.319}$$

to be true, and show that $I' \subseteq_{\mathcal{Y}} I$ is implied. To do this, we first prove the universal sentence

$$\forall A\,(A \in \mathcal{K} \Rightarrow I' \subseteq_{\mathcal{P}(X)} A), \tag{3.320}$$

letting A be arbitrary and assuming $A \in \mathcal{K}$ to hold, so that (3.319) yields $I' \subseteq_{\mathcal{Y}} A$. As before, we may apply here the specification of the reflexive partial ordering of inclusion to obtain write this first as $I' \subseteq A$, and then as $I' \subseteq_{\mathcal{P}(X)} A$. Because A is arbitrary, we may infer from this finding the truth of the universal sentence (3.320), which in turn implies $I' \subseteq_{\mathcal{P}(X)} I$ with the second part of the conjunction (3.315). Clearly, we may write this first as $I' \subseteq I$ and then as $I' \subseteq_{\mathcal{Y}} I$. As the set I' was arbitrary, we may therefore conclude that the second part of the conjunction (3.317) also holds, so that this true conjunction gives the desired consequent (3.316) of the first part of the equivalence (3.312) to be proven.

Regarding the second part ('$\Leftarrow$'), we now assume (3.316) to be true, so that the equivalent conjunction (3.317) also holds. Let us establish (3.314), by verifying the equivalent conjunction (3.315). To prove the first part

$$\forall A\,(A \in \mathcal{K} \Rightarrow I \subseteq_{\mathcal{P}(X)} A) \tag{3.321}$$

of this conjunction, we take an arbitrary set A and assume $A \in \mathcal{K}$ to be true. This assumption implies $I \subseteq_{\mathcal{Y}} A$ with the first part of the conjunction

(3.317), and this may evidently written first as the inclusion $I \subseteq A$, and then also as $I \subseteq_{\mathcal{P}(X)} A$. Since A is arbitrary, we may therefore conclude that (3.321) holds indeed. To prove the second part of the conjunction (3.315), we let I' be arbitrary, assume (3.320), and show that $I' \subseteq_{\mathcal{P}(X)} I$ follows to be true. Let us first prove that the universal sentence (3.319) is true. Indeed, letting A be arbitrary and assuming $A \in \mathcal{K}$, the assumed (3.320) gives $I' \subseteq_{\mathcal{P}(X)} A$, which we may write as $I' \subseteq A$ and then as $I' \subseteq_{\mathcal{Y}} A$. As A was arbitrary, we may therefore conclude that (3.319) is indeed true. This universal sentence implies now with the second part of the conjunction (3.317) that $I' \subseteq_{\mathcal{Y}} I$ is true. Clearly, this may be written as $I' \subseteq_{\mathcal{P}(X)} I$, which finding proves the second part of the conjunction (3.315) because I' was arbitrary. This conjunction gives now (3.314), which in turn implies $I = \bigcap \mathcal{K}$ (3.313).

Thus, the proof of the equivalence (3.312) is complete, and since X, $\mathcal{Y}$, $\mathcal{K}$ and I were initially arbitrary sets, we may now finally conclude that the proposition holds, as claimed. □

Exercise 3.44. Show for any set X, any subset $\mathcal{Y} \subseteq \mathcal{P}(X)$, any subset $\mathcal{K} \subseteq \mathcal{Y}$ and any set $S \in \mathcal{Y}$ that S is the union of $\mathcal{K}$ iff S is the supremum of $\mathcal{K}$ with respect to $\subseteq_{\mathcal{Y}}$, i.e.

$$S = \bigcup \mathcal{K} \;\Leftrightarrow\; S = \overset{\subseteq_{\mathcal{Y}}}{\sup} \mathcal{K}. \tag{3.322}$$

We now establish a useful property of complete lattices.

Corollary 3.103. *For any complete lattice $(X, \leq_X)$ and any nonempty subset A of X, it is true that the infimum of A is less than or equal to the supremum of A, i.e.*

$$\forall A\,([A \subseteq X \;\wedge\; A \neq \emptyset] \Rightarrow \inf A \leq_X \sup A). \tag{3.323}$$

Proof. We let X and $\leq_X$ be arbitrary sets such that $(X, \leq_X)$ is a complete lattice and let A be an arbitrary nonempty subset of X. It then follows with (2.42) that there exists an element in A, say $\bar{x}$. Since $\inf A$ is a lower bound for A, we have on the one hand $\inf A \leq_X \bar{x}$, and since $\sup A$ is an upper bound for A, we have on the other hand $\bar{x} \leq_X \sup A$. The conjunction of these two inequalities then implies the desired $\inf A \leq_X \sup A$ with the transitivity of the reflexive partial ordering $\leq_X$ of X. Since A is arbitrary, we therefore conclude that (3.323) holds. Then, as $(X, <_X)$ was also arbitrary, we may further conclude that the proposed sentence is true. □

Proposition 3.104. *For any partially ordered set $(X, \leq_X)$ it is true that the supremum of the pair formed by two elements a, b in X is less than or* *equal to an element c in X iff both elements a, b of the pair are less than or equal to c, i.e.*

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [\sup\{a, b\} \leq_X c \Leftrightarrow (a \leq_X c \wedge b \leq_X c)]). \tag{3.324}$$

Proof. We let X and $\leq_X$ be arbitrary sets, assume that $\leq_X$ is a reflexive partial ordering of X, let then a, b, c be arbitrary, and assume $a, b, c \in X$ to be true. To prove the first part ('$\Rightarrow$') of the stated equivalence, we assume that $\sup\{a, b\} \leq_X c$ holds. Since the supremum $\sup\{a, b\}$ is an upper bound for $\{a, b\}$ due to Theorem 3.98a), we obtain with Theorem 3.92a)

$$\begin{aligned} a &\leq_X \sup\{a, b\} \quad (\leq_X c), \\ b &\leq_X \sup\{a, b\} \quad (\leq_X c), \end{aligned}$$

which yield with the transitivity of the partial ordering $\leq_X$ the desired inequalities $a \leq_X c$ and $b \leq_X c$.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume $a \leq_X c$ and $b \leq_X c$. Thus, c is evidently an upper bound for $\{a, b\}$. As $\sup\{a, b\}$ is the supremum of $\{a, b\}$, it follows with (3.297) that $\sup\{a, b\} \leq_X c$ holds, completing the proof of the equivalence. Since X, $\leq_X$, a, b and c were arbitrary, we may therefore conclude that the proposition is true. □

Exercise 3.45. Show for any partially ordered set $(X, \leq_X)$ that the infimum of the pair formed by two elements a, b in X is greater than or equal to an element c in X iff both elements a, b of the pair are greater than or equal to c, i.e.

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [c \leq_X \inf\{a, b\} \Leftrightarrow (c \leq_X a \wedge c \leq_X b)]). \tag{3.325}$$

(Hint: Proceed in analogy to the proof of Proposition 3.104.)

Theorem 3.105. *For any partially ordered set $(X, \leq_X)$ and any subset A of X, it is true that*

a) *m is the maximum of A iff m is both the supremum of A and an element of A, i.e.*

$$\forall m\,(m = \max A \Leftrightarrow [m = \sup A \wedge m \in A]). \tag{3.326}$$

b) *m is the minimum of A iff m is both the infimum of A and an element of A, i.e.*

$$\forall m\,(m = \min A \Leftrightarrow [m = \inf A \wedge m \in A]). \tag{3.327}$$

Proof. We let X and $\leq_X$ be arbitrary sets, assume $\leq_X$ to be a reflexive partial ordering of X, let A be an arbitrary set such that $A \subseteq X$ holds, and let then m also be arbitrary.

Concerning a) and regarding the first part ('$\Rightarrow$') of the stated equivalence, we assume that $m = \max A$ holds, so that m is, by definition of a maximum, both an upper bound for A and an element of A. Thus, $m \in A$ holds, so that it remains to verify $m = \sup A$. For this purpose, we use the Characterization of the supremum. Since we already found that m is an upper bound for A, we only need to establish

$$\forall S' \, (\forall x \, (x \in A \Rightarrow x \leq_X S') \Rightarrow m \leq_X S'). \tag{3.328}$$

We let S' be arbitrary and assume

$$\forall x \, (x \in A \Rightarrow x \leq_X S').$$

With this, the previously obtained $m \in A$ implies the desired consequent $m \leq_X S'$ in (3.328). Since S' is arbitrary, we may therefore conclude that the universal sentence (3.328) is true, so that $m = \sup A$ is indeed true, besides $m \in A$.

Regarding the second part ('$\Leftarrow$') of the equivalence, we now assume $m = \sup A$ and $m \in A$ to be true. Since m is then (according to the Characterization of the supremum) an upper bound for A, and since this upper bound m for A is an element of A, it follows by definition of a maximum that $m = \max A$ is true. Thus, the proof of the equivalence is complete, and as m is arbitrary, the universal sentence (3.326) follows then to be true.

Since X, $\leq_X$ and A were also arbitrary, we may then conclude that a) holds for any X, any $\leq_X$ and any A. □

Exercise 3.46. Prove Theorem 3.105b).

The following result is then an immediate consequence of Corollary 3.96.

Corollary 3.106. *For any partially ordered set $(X, \leq_X)$ and any element y in X, it is true that y is the supremum and the infimum of the singleton formed by y, i.e.*

$$\forall y \, (y \in X \Rightarrow y = \sup\{y\} = \inf\{y\}). \tag{3.329}$$

Proposition 3.107. *For any partially ordered set $(X, \leq_X)$ and any subsets A, B of X for which the suprema of A and B exist, it is true that the supremum of A is less than or equal to the supremum of B if A is included in B, i.e.*

$$A \subseteq B \Rightarrow \sup A \leq_X \sup B. \tag{3.330}$$

Proof. We let X, $\leq_X$, A and B be arbitrary sets, assume that $\leq_X$ is a reflexive partial ordering of X, and assume also that $\sup A$ and $\sup B$ exist. To prove the stated implication directly, we assume $A \subseteq B$, which is equivalent to $\forall x\,(x \in A \Rightarrow x \in B)$ by definition of a subset. Next, we show that $\sup B$ is an upper bound for A, i.e. $\forall x\,(x \in A \Rightarrow x \leq_X \sup B)$. For this purpose, we let $x \in A$ be arbitrary and demonstrate that this implies $x \leq_X \sup B$. Let us note that $x \in A$ implies $x \in B$ in view of the assumption $A \subseteq B$. Then, as $\sup B$ is an upper bound for B, we see that $x \in B$ implies the desired $x \leq_X \sup B$. Since x is arbitrary, we therefore conclude that $\sup B$ is an upper bound for A. Consequently, as $\sup A$ is the least upper of A, we obtain $\sup A \leq_X \sup B$, which completes the proof of the implication (3.330). As X, $\leq_X$, A and B were arbitrary, we may now conclude that the proposition is true. □

Exercise 3.47. Show for any partially ordered set $(X, \leq_X)$ and any subsets A, B of X for which the infima of A and B exist that the infimum of B is less than or equal to the infimum of A if A is included in B, i.e.

$$A \subseteq B \Rightarrow \inf B \leq_X \inf A. \tag{3.331}$$

Theorem 3.108 (Nested determination of the supremum & the infimum). *The following equations hold for any partially ordered set $(X, \leq_X)$ and any $a, b, c \in X$ such that the suprema/infima of $\{a, b, c\}$ and $\{a, b\}$ exist.*

$$\sup\{a, b, c\} = \sup\{\sup\{a, b\}, c\}, \tag{3.332}$$

$$\inf\{a, b, c\} = \inf\{\inf\{a, b\}, c\}. \tag{3.333}$$

Proof. We let X, $\leq_X$, a, b and c be arbitrary, assume that $\leq_X$ is a reflexive partial ordering of X, assume that a, b, c are in X, and assume concerning (3.332) also that $S = \sup\{a, b, c\}$ as well as $\sup\{a, b\}$ exist (in X). To show that the constant S is the supremum of $\{\sup\{a, b\}, c\}$, as claimed, we apply the Characterization of the supremum. To show that S is an upper bound for $\{\sup\{a, b\}, c\}$, we first note that both $\{a, b\}$ and $\{c\}$ are subsets of $\{a, b, c\}$ according to (2.237), so that we obtain $\sup\{a, b\} \leq_X S$ and $\sup\{c\} \leq_X S$ with Proposition 3.107. Since Corollary 3.106 gives $\sup\{c\} = c$, the preceding conjunction gives $\sup\{a, b\} \leq_X S \wedge c \leq_X S$, which in turn implies with the Characterization of upper bounds for pairs that S is an upper bound for $\{\sup\{a, b\}, c\}$.

Next, we verify (according to the Characterization of the supremum) that S is less than or equal to any upper bound S' for $\sup\{\{a, b\}, c\}$, i.e.

$$\forall S'\,(\forall x\,(x \in \sup\{\{a, b\}, c\} \Rightarrow x \leq_X S') \Rightarrow S \leq_X S') \tag{3.334}$$

For this purpose, we let S' be arbitrary and assume the universal sentence in (3.334) to be true, i.e. we assume S' to be an upper bound for $\sup\{\{a,b\},c\}$, so that the conjunction $\sup\{a,b\} \leq_X S' \wedge c \leq_X S'$ holds (according to the Characterization of upper bounds for pairs), and we demonstrate that this implies $S \leq_X S'$. Now, as $\{a\}$ and $\{b\}$ are subsets of $\{a,b\}$ due to (2.185), we obtain

$$\begin{aligned} (a =) \quad \sup\{a\} &\leq_X \sup\{a,b\} \quad (\leq_X S'), \\ (b =) \quad \sup\{b\} &\leq_X \sup\{a,b\} \quad (\leq_X S'), \end{aligned}$$

using again Corollary 3.106, Proposition 3.107 (as well as the previously established inequality $\sup\{a,b\} \leq_X S'$). Then, the transitivity of the partial ordering $\leq_X$ gives $a \leq_X S'$ and $b \leq_X S'$, alongside the previously obtained $c \leq_X S'$. These findings imply with Theorem 3.93a) that S' is an upper bound for the triple $\{a,b,c\}$, that is,

$$\forall x\,(x \in \{a,b,c\} \Rightarrow x \leq_X S'). \tag{3.335}$$

Since we defined $S = \sup\{a,b,c\}$ to be the supremum of $\{a,b,c\}$, it follows now from (3.335) with the Characterization of the supremum that $S \leq_X S'$ is true, which completes the proof of the implication in (3.334). Because S' is arbitrary, we may infer from this the truth of the universal sentence (3.334), which completes the proof that S is the supremum of $\{\sup\{a,b\},c\}$. Since X, $\leq_X$, a, b and c were arbitrary, we may finally conclude that the first part of the theorem holds. □

Exercise 3.48. Verify the second equation of Theorem 3.108.

Proposition 3.109. *For any lattice $(X, \leq_X)$ it is true that, if an element a of X is less than or equal to an element b of X, then the supremum of the pair formed by a and b is identical with b, and the infimum of that pair equals a, that is,*

$$\forall a,b\,(a,b \in X \Rightarrow [a \leq_X b \Rightarrow (\sup\{a,b\} = b \wedge \inf\{a,b\} = a)]). \tag{3.336}$$

Proof. We let X and $\leq_X$ be arbitrary sets and assume that $(X, \leq_X)$ is a lattice. Next, we let a and b be arbitrary and assume $a,b \in X$ to be true. Let us now observe that $a,b \in X$ implies $a \leq_X a$ as well as $b \leq_X b$ since $\leq_X$ is reflexive. Next, we assume that $a \leq_X b$ holds. Consequently, the conjunctions $a \leq_X b \wedge b \leq_X b$ and $a \leq_X a \wedge a \leq_X b$ are true. It then follows with the Characterization of upper & lower bounds for a pair that b is an upper bound and that a is a lower bound for $\{a,b\}$. Since $a,b \in \{a,b\}$ is also true according to Exercise 2.15, we see that $b = \max\{a,b\}$ and $a = \min\{a,b\}$ hold by definition of a greatest and of a least element. These equations in turn imply, respectively, $b = \sup\{a, b\}$ and $a = \inf\{a, b\}$ with Theorem 3.105. Thus, the proof of the conjunction in (3.336) is complete, so that the implications follow to be true. Since a and b are arbitrary, we may therefore conclude that the proposition holds. □

Proposition 3.110. *For any lattice $(X, \leq_X)$ it is true that the infimum of the pair formed by two elements of X is less than or equal to the supremum of that pair, i.e.*

$$\forall a, b\,(a, b \in X \Rightarrow \inf\{a, b\} \leq_X \sup\{a, b\}). \tag{3.337}$$

Proof. Letting X and $\leq_X$ be arbitrary such that $(X, \leq_X)$ is a lattice and letting a and b be arbitrary such that $a, b \in X$ is true, we see in light of the Characterization of the supremum & the infimum that $\sup\{a, b\}$ is an upper bound and $\inf\{a, b\}$ a lower bound for $\{a, b\}$, so that the universal sentences

$$\forall x\,(x \in \{a, b\} \Rightarrow x \leq_X \sup\{a, b\})$$
$$\forall x\,(x \in \{a, b\} \Rightarrow \inf\{a, b\} \leq_X x)$$

are both true. Then, the evident fact that $a \in \{a, b\}$ is true implies on the one hand $a \leq_X \sup\{a, b\}$, and on the other hand $\inf\{a, b\} \leq_X a$. Since the partial ordering $\leq_X$ is transitive, it follows from these two findings that $\inf\{a, b\} \leq_X \sup\{a, b\}$ holds, so that the implication in (3.337) is true. Then, since X, $\leq_X$, a and b are arbitrary, it follows that the proposed universal sentence holds, as claimed. □

Exercise 3.49. Show for any complete lattice $(X, \leq_X)$ that the infimum of a nonempty subset A of X is less than or equal to the supremum of that subset, i.e.

$$\forall A\,([A \subseteq X \wedge A \neq \emptyset] \Rightarrow \inf A \leq_X \sup A). \tag{3.338}$$

(Hint: Proceed in analogy to the proof of Proposition 3.110, applying now (2.42).)

In case of a linear ordering, the definition of the supremum can be shown to be equivalent to the following often applied formulation: If we take an element S' of X which is less than the supremum S of A, then there exists an element x in A which is greater than S', so that S' cannot be an upper bound for A, *a fortiori* not the supremum of A. The infimum is characterized analogously.

Theorem 3.111 (Supremum & Infimum Criterion). *For any linearly ordered set $(X, <_X)$ and any nonempty subset A of X, it is true that* *a) an element S in X is the supremum of A iff*

$$\begin{aligned}&\forall x\,(x \in A \Rightarrow x \leq_X S)\\&\quad\wedge\ \forall S'\,([S' \in X \ \wedge\ S' <_X S] \Rightarrow \exists x\,(x \in A \ \wedge\ S' <_X x)).\end{aligned} \tag{3.339}$$

b) an element I in X is the infimum of A iff

$$\begin{aligned}&\forall x\,(x \in A \Rightarrow I \leq_X x)\\&\quad\wedge\ \forall I'\,([I' \in X \ \wedge\ I <_X I'] \Rightarrow \exists x\,(x \in A \ \wedge\ x <_X I')).\end{aligned} \tag{3.340}$$

Proof. We let X, $<_X$ and $\leq_X$ be arbitrary sets such that $<_X$ is a linear ordering and $\leq_X$ a total ordering of X inducing each other,and we let A be an arbitrary nonempty subset of X.

Concerning a), we let S be arbitrary and assume $S \in X$ to be true. To prove the first part ('$\Rightarrow$') of the stated equivalence, we assume (3.339) and show that this implies (3.297). Clearly, the first part of the assumed conjunction (3.339) is then true and therefore immediately implies the truth of the identical first part of the conjunction (3.297), which characterizes the supremum of A. Next, we demonstrate that the second part

$$\forall S'\,([S' \in X \ \wedge\ S' <_X S] \Rightarrow \exists x\,(x \in A \ \wedge\ S' <_X x)) \tag{3.341}$$

of the assumed conjunction (3.339) also implies the truth of the second part

$$\forall S'\,([S' \in X \ \wedge\ \forall x\,(x \in A \Rightarrow x \leq_X S')] \Rightarrow S \leq_X S') \tag{3.342}$$

of the conjunction (3.297). To prove the latter universal sentence, we let $\bar{S}'$ be arbitrary, and we prove the implication

$$[\bar{S}' \in X \ \wedge\ \forall x\,(x \in A \Rightarrow x \leq_X \bar{S}')] \Rightarrow S \leq_X \bar{S}' \tag{3.343}$$

by contradiction, assuming $\bar{S}' \in X$, the universal sentence

$$\forall x\,(x \in A \Rightarrow x \leq_X \bar{S}') \tag{3.344}$$

and $\neg S \leq_X \bar{S}'$ to be true. Since S and $\bar{S}'$ are thus elements of X, we have that $\neg S \leq_X \bar{S}'$ implies $S >_X \bar{S}'$ with the negation Formula for $\leq$. Thus, the conjunction of $\bar{S}' \in X$ and $\bar{S}' <_X S$ is true, which then implies with the initial assumption $A \neq \emptyset$ and with (3.341) that there exists an element in A, say $\bar{x}$, such that $\bar{S}' <_X \bar{x}$ holds. As we initially assumed $A \subseteq X$, we then see that $\bar{x} \in A$ implies $\bar{x} \in X$ by definition of a subset. Thus, $\bar{S}'$ and $\bar{x}$ are both in X, so that the preceding inequality $\bar{S}' <_X \bar{x}$ implies $\neg\bar{x} \leq_X \bar{S}'$ with the Negation Formula for $\leq$. Furthermore, $\bar{x} \in A$ implies $\bar{x} \leq_X \bar{S}'$

with (3.344), which evidently contradicts the preceding negation, so that the proof of the implication (3.343) is complete. Because $\bar{S}'$ is arbitrary, we may therefore conclude that the universal sentence (3.342) is true, which completes the proof of the conjunction (3.297) and thus the proof of the first part of the proposed equivalence.

To prove the second part ('$\Leftarrow$'), we now assume (3.297) to be true and establish the truth of (3.339). Then, the first part of the conjunction (3.297) implies the first part of the conjunction (3.339), because both are identical. It now remains for us to verify that the second part (3.342) of the assumed conjunction implies the truth of the second part (3.341) of the conjunction to be proven. Letting $\bar{S}'$ be arbitrary, we now prove the implication in (3.341) directly, assuming $\bar{S}' \in X$ and $\bar{S}' <_X S$ to hold. Thus, $\bar{S}'$ and S are both elements of X, and therefore the assumed inequality $\bar{S}' <_X S$ implies $\neg S \leq_X \bar{S}'$ with the Negation Formula for $\leq$. Let us now observe that the implication in (3.342) holds for $\bar{S}'$, so that we may apply the Law of Contraposition to infer from $\neg S \leq_X \bar{S}'$ the truth of the negation

$$\neg[\bar{S}' \in X \wedge \forall x\,(x \in A \Rightarrow x \leq_X \bar{S}')].$$

It then follows with De Morgan's Law (1.51) that $\bar{S}' \notin X$ or

$$\neg\forall x\,(x \in A \Rightarrow x \leq_X \bar{S}')$$

holds. Here, $\bar{S}' \notin X$ is false as we assumed $\bar{S}' \in X$ to be true. Consequently, the preceding negated universal sentence is true, which we may then write equivalently as

$$\exists x\,(x \in A \wedge \neg x \leq_X \bar{S}'),$$

applying the Double Negation Law and (1.82). Thus, there exists an element in A, say $\bar{x}$, such that $\neg\bar{x} \leq_X \bar{S}'$ holds. Recalling the initial assumption $A \subseteq X$, we also see that $\bar{x} \in A$ implies $\bar{x} \in A$ with the definition of a subset. Thus, $\bar{x}$ and $\bar{S}'$ are both in X, and therefore the preceding negation $\neg\bar{x} \leq_X \bar{S}'$ implies $\bar{S}' <_X \bar{x}$ with the Negation Formula for $\leq$. This proves the existence of an element x satisfying the conjunction $x \in A \wedge \bar{S}' <_X x$, which in turn proves the implication in (3.341). Since $\bar{S}'$ is arbitrary, the universal sentence (3.341) then follows to be true, so that the second part of the conjunction (3.339) to be proven also holds. Thus, the proof of the second part of the proposed equivalence is complete, and therefore the equivalence is itself true. As X, $<_X$, $\leq_X$, A and S were arbitrary, we may now conclude that Part a) of the theorem is true. $\square$

Exercise 3.50. Prove the Infimum Criterion.

Theorem 3.112 (Equality Criterion for suprema & infima). *It is true for any linearly ordered set* $(X, <_X)$ *and any sets* $A, B \subseteq X$ *with* $A \subseteq B$ *such that*

a) the suprema $\sup A$ *and* $\sup B$ *exist that these suprema are identical if, for any element* x *in* B*, there exists an element* y *in* A *which is greater than or equal to* x*, i.e.,*

$$\forall x\,(x \in B \Rightarrow \exists y\,(y \in A \wedge y \geq_X x)) \Rightarrow \sup A = \sup B. \tag{3.345}$$

b) the infima $\inf A$ *and* $\inf B$ *exist that these infima are identical if, for any element* x *in* B*, there exists an element* y *in* A *which is less than or equal to* x*, i.e.,*

$$\forall x\,(x \in B \Rightarrow \exists y\,(y \in A \wedge y \leq_X x)) \Rightarrow \inf A = \inf B. \tag{3.346}$$

Proof. We let X, $\leq_X$, A and B be arbitrary sets such that $(X, \leq_X)$ is linearly ordered, such that the inclusions $A \subseteq X$, $B \subseteq X$ and $A \subseteq B$ hold, and such that $\sup A$ and $\sup B$ exist. We note that these assumptions imply $\sup A \leq_X \sup B$ with Proposition 3.107. We now prove the implication (3.345) by contradiction, assuming its antecedent and the negation $\neg \sup A = \sup B$ to be true. Since the linear ordering $<_X$ is connex, this implies the truth of the disjunction $\sup A <_X \sup B \vee \sup B <_X \sup A$. As the previously found inequality $\sup A \leq_X \sup B$ implies $\neg \sup B <_X \sup A$, the first part $\sup A <_X \sup B$ of the disjunction must be true. Noting that $S' = \sup A$ is an element of X, it follows from $S' <_X \sup B$ with the Supremum Criterion that there exists a particular element $\bar{x} \in B$ which is greater than S', i.e., which satisfies $[\sup A =]\ S' <_X \bar{x}$. Due to the assumed antecedent, it follows from $\bar{x} \in B$ that there exists a particular element $\bar{y} \in A$ which satisfies $\bar{y} \geq_X \bar{x}$. Since the supremum $\sup A$ is by definition an upper bound for A, $\bar{y} \in A$ implies $[\bar{x} \leq_X]\ \bar{y} \leq_X \sup A$. These inequalities in turn give us $\bar{x} \leq_X \sup A$ with the transitivity of the induced total ordering $\leq_X$. In conjunction with the previously found inequality $\sup A <_X \bar{x}$, this further implies $\sup A <_X \sup A$ with the Transitivity Formula for $<$ and $\leq$. This finding contradicts the true negation $\neg \sup A <_X \sup A$, which holds due to the irreflexivity of the linear ordering $<_X$. We thus completed the proof of the implication (3.345).

The second implication (3.346) can be proved similarly. Since X, $\leq_X$, A and B were initially arbitrary, we therefore conclude that the theorem is true. □

Exercise 3.51. Establish the Equality Criterion for infima.

Proposition 3.113. *The following sentences are true for any totally ordered set $(X, \leq_X)$ and any $a, b \in X$.*

a) *$\{a, b\}$ is bounded from above by a or by b.*

b) *The maximum of $\{a, b\}$ is identical with a or with b, that is,*

$$\max\{a, b\} = a \lor \max\{a, b\} = b. \tag{3.347}$$

c) *The supremum of $\{a, b\}$ is identical with a or with b, and moreover identical with the maximum of $\{a, b\}$, that is,*

$$(\sup\{a, b\} = a \lor \sup\{a, b\} = b) \land \sup\{a, b\} = \max\{a, b\}. \tag{3.348}$$

Proof. We let X, $\leq_X$, a and b be arbitrary, assume that $(X, \leq_X)$ is totally ordered, and assume furthermore that and $a, b \in X$ is true.

Concerning a), we note that $a \leq_X a$ and $b \leq_X b$ are true since the total ordering $\leq_X$ is reflexive. Furthermore, the disjunction $a \leq_X b \lor b \leq_X a$ holds because $\leq_X$ is total. Now, in case $a \leq_X b$ is true, the conjunction $a \leq_X b \land b \leq_X b$ also holds, so that b is an upper bound for $\{a, b\}$ in view of Theorem 3.92a). Similarly, in the other case that $b \leq_X a$ is true, the conjunction $a \leq_X a \land b \leq_X a$ also holds, so that a is now an upper bound for $\{a, b\}$. We thus showed that $\{a, b\}$ is bounded from above by a or by b.

Concerning b), let us first observe that a and b are clearly elements of $\{a, b\}$. Now, in case a is an upper bound for A, it follows together with $a \in A$ that a is the maximum of A by definition. Similarly, if b is an upper bound for A, then this implies with $b \in A$ that b is the maximum of A.

Concerning c), in case a is the maximum of $\{a, b\}$, it follows with Theorem 3.105a) that a is also the supremum of A. Similarly, in the other case that b is the maximum of $\{a, b\}$, this implies that b is the supremum of $\{a, b\}$.

As X, $\leq_X$, a and b were arbitrary, we may therefore conclude that the proposition is true. □

Exercise 3.52. The following sentences are true for any totally ordered set $(X, \leq_X)$ and any $a, b \in X$.

a) $\{a, b\}$ is bounded from below by a or by b.

b) The minimum of $\{a, b\}$ is identical with a or with b, that is,

$$\min\{a, b\} = a \lor \min\{a, b\} = b. \tag{3.349}$$

c) The infimum of $\{a,b\}$ is identical with a or with b, and moreover identical with the minimum of $\{a,b\}$, that is,

$$(\inf\{a,b\} = a \vee \inf\{a,b\} = b) \wedge \inf\{a,b\} = \min\{a,b\}. \tag{3.350}$$

Corollary 3.114. *Any totally ordered set $(X, \leq_X)$ with $X \neq \emptyset$ is a lattice.*

Proof. Letting X and $\leq_X$ be arbitrary sets, assuming $X \neq \emptyset$, and assuming $\leq_X$ to be a total ordering of X, we see in light of Proposition 3.113c) and Exercise 3.52c) that both the supremum and the infimum exist for any pair $\{a,b\}$. This is then true for any X and any $\leq_X$. $\square$

The preceding corollary allows us to obtain the following simple examples of a lattice.

Corollary 3.115. *For any x the ordered pair $(\{x\}, \{(x,x)\})$ is a lattice.*

Proof. Letting x be arbitrary, we have that due to Corollary 3.70 that $(\{x\}, \{(x,x)\})$ is a totally ordered set. Now, since $x \in \{x\}$ holds according to (2.153), we see that there exists an element in $\{x\}$, so that $\{x\} \neq \emptyset$ follows to be true with (2.42). Consequently, $(\{x\}, \{(x,x)\})$ is a lattice in view of Corollary 3.114. Since x was arbitrary, we may therefore conclude that the proposed universal sentence is true. $\square$

Corollary 3.116. *For any x and any y satisfying $x \neq y$ the ordered pair $(\{x,y\}, \{(x,x),(x,y),(y,y)\})$ is a lattice.*

Proof. We take arbitrary x and y, assume $x \neq y$ to be true, and recall from Corollary 3.85 that $(\{x,y\}, \{(x,x),(x,y),(y,y)\})$ is a totally ordered set, where $\{x,y\}$ is evidently nonempty since $x, y \in \{x,y\}$ holds according to (2.151). Thus, Corollary 3.114 shows that $(\{x,y\}, \{(x,x),(x,y),(y,y)\})$ is a lattice, which is then true for any x and any y. $\square$

3.3.4. Intervals

We end the current section with the introduction of another basic type of set that arises frequently in the context of ordered sets.

Proposition 3.117. *The following sentences are true for any partially ordered set* $(X, \leq_X)$ *and for any elements* $a, b \in X$.

a) There exists a unique set $[a,b]$ *such that an element* x *is in* $[a,b]$ *iff (1)* x *is in* X*, (2)* x *is greater than or equal to* a *and (3)* x *is less than or equal to* b*, that is,*

$$\exists![a,b]\, \forall x\, (x \in [a,b] \Leftrightarrow [x \in X \,\wedge\, (x \geq_X a \,\wedge\, x \leq_X b)]). \tag{3.351}$$

b) The set $[a,b]$ *is a subset of* X*, that is,*

$$[a,b] \;\subseteq\; X. \tag{3.352}$$

c) Furthermore, an element x *is in* $[a,b]$ *if, and only if,* x *is between* a *and* b*, that is,*

$$\forall x\, (x \in [a,b] \Leftrightarrow a \leq_X x \leq_X b). \tag{3.353}$$

a is a lower bound and b an upper bound for $[a,b]$ with respect to $\leq_X$.

d) Moreover, the set $[a,b]$ *is nonempty iff* a *is less than or equal to* b*, that is,*

$$[a,b] \neq \emptyset \;\Leftrightarrow a \leq_X b. \tag{3.354}$$

e) There exists a unique set $\{[a,b] : a, b \in X\}$ *consisting of all the sets* $[a,b]$ *in* $\mathcal{P}(X)$ *with* $a, b \in X$*, and this set satisfies*

$$\forall Z\, (Z \in \{[a,b] : a,b \in X\} \Leftrightarrow \exists a, b\, (a, b \in X \,\wedge\, [a,b] = Z)). \tag{3.355}$$

f) The set $\{[a,b] : a,b \in X\}$ *is included in the power set of* X*, that is,*

$$\{[a,b] : a,b \in X\} \;\subseteq\; \mathcal{P}(X). \tag{3.356}$$

Proof. We let X, $\leq_X$, a and b be arbitrary, assume $\leq_X$ to be a reflexive partial ordering of X, and assume $a, b \in X$ to be true.

Concerning a), we may evidently apply the Axiom of Specification together with the Equality Criterion for sets to establish the uniquely existential sentence (3.351). Thus, the set $[a,b]$ satisfies

$$\forall x\, (x \in [a,b] \Leftrightarrow [x \in X \,\wedge\, (x \geq_X a \,\wedge\, x \leq_X b)]). \tag{3.357}$$

Concerning b), we notice in light of (3.357) that $x \in [a, b]$ implies in particular $x \in X$ for any X, so that the inclusion (3.352) follows to be true by definition of a subset.

Concerning c), we take an arbitrary x and assume first $x \in [a, b]$ to be true. This assumption implies with (3.357) in particular the truth of $x \geq_X a \wedge x \leq_X b$, which conjunction we may write also as $a \leq_X x \leq_X b$. We thus proved the first part ('⇒') of the equivalence in (3.353). To establish the second part ('⇐'), we now assume $a \leq_X x \leq_X b$ to be true, which conjunction we may write first as $x \geq_X a \wedge x \leq_X b$, and then also $(a, x) \in \leq_X \wedge (x, b) \in \leq_X$, recalling that $\leq_X$ is by definition a binary relation on X. Thus, the inclusion $\leq_X \subseteq X \times X$ holds, so that the two parts of the preceding conjunction imply $(a, x), (x, b) \in X \times X$ by definition of a subset, and therefore especially $x \in X$ with the definition of the Cartesian product of two sets. We thus showed that $x \in X$ and $x \geq_X a \wedge x \leq_X b$ are both true, so that $x \in [a, b]$ follows to be also true with (3.357), completing the proof of the equivalence in (3.353). Because x is arbitrary, we may therefore conclude that the universal sentence (3.353) is true. Then, since $x \in [a, b]$ evidently implies in particular $a \leq_X x$ for any x, we have that a is a lower bound for $[a, b]$, by definition. Similarly, $x \in [a, b]$ implies in particular $x \leq_X b$ for any x, so that b is by definition an upper bound for $[a, b]$.

Concerning d), we prove the first part ('⇒') of the equivalence directly, assuming $[a, b] \neq \emptyset$ to hold. Then, there exists a particular element $\bar{x} \in [a, b]$, according to (2.42), so that $a \leq_X \bar{x} \leq_X b$ follows to be true with (3.353). As the reflexive partial ordering $\leq_X$ is transitive by definition, the preceding inequalities imply $a \leq_X b$, as desired. Next, we prove the second part ('⇐') of the equivalence by assuming $a \leq_X b$ to be true. Since $\leq_X$ is reflexive, the inequality $a \leq_X a$ also holds, so that we obtained the two inequalities $a \leq_X a \leq_X b$. These now give $a \in [a, b]$ due to (3.353), which finding clearly shows that $[a, b]$ is not empty. Thus, the proof of the equivalence is complete. Concerning e), we can use again the Axiom of Specification in connection with the Equality Criterion for sets to prove the unique existence of a set $\{[a, b] : a, b \in X\}$ such that

$$\forall Z \, (Z \in \{[a, b] : a, b \in X\} \Leftrightarrow [Z \in \mathcal{P}(X) \wedge \exists a, b \, (a, b \in X \wedge [a, b] = Z)]). \tag{3.358}$$

Next, we take an arbitrary set Z, assuming first $Z \in \{[a, b] : a, b \in X\}$. Consequently, we obtain with (3.358) in particular the desired existential sentence in (3.355). Let us now conversely assume that there exist constants a and b satisfying $a, b \in X \wedge [a, b] = Z$, say $\bar{a}$ and $\bar{b}$. According to b), we thus have $Z \subseteq X$ and therefore $Z \in \mathcal{P}(X)$ by definition of a power set. Together with the assumed existential sentence, this gives with (3.358) the desired consequent $Z \in \{[a,b] : a,b \in X\}$, so that the proof of the equivalence in (3.355) is complete. As Z is arbitrary, we may infer from the truth of that equivalence the truth of the universal sentence (3.355).

Finally, concerning f), we see in light of (3.358) that $Z \in \{[a,b] : a,b \in X\}$ implies in particular $Z \in \mathcal{P}(X)$ for any Z, so that the stated inclusion follows to be true by definition of a subset.

Since X, $\leq_X$, a and b were initially arbitrary, we may therefore conclude that the proposition holds. □

Definition 3.32 (Closed interval, set of closed intervals). For any partially ordered set $(X, \leq_X)$ and any elements $a, b \in X$, we call the unique set

$$[a,b]_X = [a,b] \tag{3.359}$$

consisting of all the elements in X between a and b in the sense of

$$\forall x\, (x \in [a,b]_X \Leftrightarrow a \leq_X x \leq_X b)$$

the *closed interval* from a to b (with respect to $\leq_X$). Furthermore, we call

$$\{[a,b] : a,b \in X\} \tag{3.360}$$

the *set of closed intervals* in X (with respect to $\leq_X$).

Corollary 3.118. *For any partially ordered set $(X, \leq_X)$ and for any elements $a, b \in X$ with $a \leq_X b$, it is true that a is the minimum/infimum and b the maximum/supremum of $[a,b]$, that is,*

$$\min\,[a,b] = a = \inf\,[a,b], \tag{3.361}$$

$$\max\,[a,b] = b = \sup\,[a,b]. \tag{3.362}$$

Proof. Letting X, $\leq_X$, a and b be arbitrary such that $\leq_X$ is a reflexive partial ordering of X, such that $a, b \in X$ and such that $a \leq_X b$ holds, we observe in light of Proposition 3.117c) that a is a lower and b an upper bound for $[a,b]$. Then, because $\leq_X$ is reflexive and because of the assumption $a \leq_X b$, the inequalities

$$a \leq_X a \leq_X b$$

$$a \leq_X b \leq_X b$$

hold, so that $a, b \in [a,b]$ follows to be true again with Proposition 3.117c). Consequently, we obtain the first equation in (3.361) and in (3.362) with the definition of a minimum & of a maximum. In addition, the respective second equations follow to be true with Theorem 3.105. As X, $\leq_X$, a and b were arbitrary, we may therefore conclude that the corollary is true. □

Proposition 3.119. *For any partially ordered set $(X, \leq_X)$, where the reflexive partial ordering $\leq_X$ induces the irreflexive partial ordering $<_X$ of X, and for any element $a \in X$, it is true that the closed interval from a to a is identical with the singleton formed by a, i.e.*

$$[a, a] = \{a\}. \tag{3.363}$$

Proof. Letting X, $\leq_X$ and a be arbitrary, we assume that $(X, \leq_X)$ is partially ordered and that a is in X. Let us apply the Equality Criterion for sets to establish $[a, a] = \{a\}$. We thus need to prove the universal sentence

$$\forall x\, (x \in [a, a] \Leftrightarrow x \in \{a\}). \tag{3.364}$$

Letting x be arbitrary, we first assume $x \in [a, a]$, so that $a \leq_X x \wedge x \leq_X a$ holds by definition of a closed interval. Because the reflexive partial ordering $\leq_X$ is antisymmetric, the preceding conjunction implies $x = a$, which equation in turn implies the desired consequent $x \in \{a\}$ with (2.169). To establish the second part of the equivalence, we now assume conversely $x \in \{a\}$ to be true, so that $x = a$ holds according to (2.169). Then, letting $<_X$ be the irreflexive partial ordering of X induced by $\leq_X$, the two disjunctions

$$a <_X x \vee a = x$$
$$x <_X a \vee x = a$$

are evidently also both true, which now imply $a \leq_X x$ as well as $x \leq_X a$ by definition of an induced irreflexive partial ordering. Thus, $x \in [a, a]$ holds by definition of a closed interval, which finding completes the proof of the equivalence. As x was arbitrary, we may therefore conclude that the universal sentence (3.364) is true, which in turn implies the truth of the equation (3.363). Since X, $\leq_X$ and a were initially arbitrary, we may infer from this the truth of the stated proposition. □

Theorem 3.120 (Generation of lattices based on closed intervals). *For any lattice $(X, \leq_X)$ and any elements $a, b \in X$ with $a \leq_X b$, it is true that the ordered pair $([a, b], \leq_{[a,b]})$ is a also a lattice.*

Proof. We take arbitrary sets X and $\leq_X$ such that $(X, \leq_X)$ is a lattice, and we take arbitrary elements $a, b \in X$ satisfying $a \leq_X b$, so that the closed interval $[a, b]$ is a nonempty subset of X due to Proposition 3.117b). According to the Reflexive partial ordering of subsets, there exists then the unique reflexive partial ordering $\leq_{[a,b]}$ of the closed interval $[a, b]$, which satisfies

$$\forall x, y\, (x, y \in [a, b] \Rightarrow [a \leq_{[a,b]} b \Leftrightarrow a \leq_X b]). \tag{3.365}$$

To prove that the partially ordered set $([a,b], \leq_{[a,b]})$ is a lattice, we observe first that the initial assumption $a \leq_X b$ implies $[a,b] \neq \emptyset$ with Proposition 3.117d). Next, we verify the universal sentence

$$\forall x, y\, (x, y \in [a,b] \Rightarrow \exists S, I\, (S, I \in [a,b] \wedge S = \sup^{\leq_{[a,b]}}\{x,y\} \wedge I = \inf^{\leq_{[a,b]}}\{x,y\})). \tag{3.366}$$

To do this, we take arbitrary constants x and y, and we assume $x, y \in [a,b]$ to be true. Consequently, $x, y \in X$ holds due to the mentioned inclusion $[a,b] \subseteq X$, so that there are constants, say $\bar{S}$ and $\bar{I}$, satisfying $\bar{S}, \bar{I} \in X$, $\bar{S} = \sup^{\leq_X}\{x,y\}$, and $\bar{I} = \inf^{\leq_X}\{x,y\}$, because $(X, \leq_X)$ is a lattice. Thus, $\bar{S}$ is an upper and $\bar{I}$ a lower bound for $\{x,y\}$ (with respect to $\leq_X$). Therefore, the Characterization of upper & lower bounds for pairs yields, respectively,

$$x \leq_X \bar{S} \wedge y \leq_X \bar{S} \tag{3.367}$$

and

$$\bar{I} \leq_X x \wedge \bar{I} \leq_X y. \tag{3.368}$$

Furthermore, the inequalities

$$a \leq_X x \wedge x \leq_X b \tag{3.369}$$

as well as

$$a \leq_X y \wedge y \leq_X b \tag{3.370}$$

are true according to Proposition 3.117c); thus, the conjunction

$$x \leq_X b \wedge y \leq_X b$$

and the conjunction

$$a \leq_X x \wedge a \leq_X y$$

are true, which show in light of the Characterization of upper & lower bounds for pairs that b is an upper and a a lower bound for $\{x,y\}$ (with respect to $\leq_X$). Since $\bar{S}$ is the least upper and $\bar{I}$ the greatest lower bound for $\{x,y\}$ (with respect to $\leq_X$), we have

$$\bar{S} \leq_X b \tag{3.371}$$

and

$$a \leq_X \bar{I}. \tag{3.372}$$

Let us now combine the first inequality in (3.369), the first one in (3.367) and the inequality in (3.371) to

$$a \leq_X x \leq_X \bar{S} \leq_X b,$$

and similarly the inequality in (3.372), the first one in (3.368) and the second one in (3.369) to

$$a \leq_X \bar{I} \leq_X x \leq_X b.$$

As the reflexive partial ordering $\leq_X$ is transitive, we therefore obtain

$$a \leq_X \bar{S} \leq_X b$$

as well as

$$a \leq_X \bar{I} \leq_X b,$$

consequently $\bar{S}, \bar{I} \in [a, b]$ with (3.353), as required by the desired existential sentence in (3.366). In addition, because x, y, $\bar{S}$ and $\bar{I}$ are thus all elements in $[a, b]$, we may write (3.367) – (3.368) equivalently as

$$x \leq_{[a,b]} \bar{S} \wedge y \leq_{[a,b]} \bar{S}$$

and

$$\bar{I} \leq_{[a,b]} x \wedge \bar{I} \leq_{[a,b]} y.$$

respectively, by applying (3.365). These inequalities clearly show that $\bar{S}$ is an upper and $\bar{I}$ a lower bound for the pair $\{x, y\}$ with respect to $\leq_{[a,b]}$. To prove that $\bar{S}$ is the least upper and $\bar{I}$ the greatest lower bound for $\{x, y\}$, we apply the Characterization of the supremum & infimum, letting S' and I' be arbitrary constants such that S' is an upper and I' a lower bound for $\{x, y\}$ with respect to $\leq_{[a,b]}$, so that the inequalities

$$x \leq_{[a,b]} S' \wedge y \leq_{[a,b]} S'$$

and

$$I' \leq_{[a,b]} x \wedge I' \leq_{[a,b]} y.$$

are evidently true. Thus, x, y, S' and I' are all elements in $[a, b]$, so that we may write the preceding inequalities also as

$$x \leq_X S' \wedge y \leq_X S'$$

and

$$I' \leq_X x \wedge I' \leq_X y.$$

These inequalities show now that S' is an upper and I' a lower bound for $\{x, y\}$ also with respect to $\leq_X$. Then, as $\bar{S}$ is the least upper and $\bar{I}$ the greatest lower bound for $\{x, y\}$ with respect to $\leq_X$ (whose existence we established previously), we obtain

$$\bar{S} \leq_X S'$$

and

$$I' \leq_X \bar{I}$$

with the Characterization of the supremum & infimum. We already mentioned before that $\bar{S}$, S', $\bar{I}$ and I' are elements in $[a,b]$, which allows us to write these two inequalities equivalently as

$$\bar{S} \leq_{[a,b]} S'$$

and

$$I' \leq_{[a,b]} \bar{I}.$$

Since S' and I' were arbitrary, we may infer from these findings that the upper bound $\bar{S}$ for $\{x,y\}$ is indeed the least one and that the lower bound $\bar{I}$ for $\{x,y\}$ is the greatest one for $\{x,y\}$ (with respect to $\leq_{[a,b]}$). Thus, the proof of the existential sentence in (3.366) is complete, and as x and y were arbitrary, we may therefore conclude that the universal sentence (3.366) is true. This means that the partially ordered set $([a,b], \leq_{[a,b]})$ is a lattice, by definition. Because X, $\leq_X$, a and b were initially also arbitrary, we may now finally conclude that the stated theorem holds. □

Note 3.13. For any lattice $([a,b], \leq_{[a,b]})$ generated by a lattice $(X, \leq_X)$, we have the underlying assumption $a \leq_X b$, so that a is the bottom and b the top of $[a,b]$ according to Corollary 3.118.

Exercise 3.53. Prove the following sentences for any partially ordered set $(X, \leq_X)$ and for any elements $a, b \in X$.

a) There exist unique sets (a,b), $(a,b]$ and $[a,b)$ such that

$$\forall x\,(x \in (a,b) \Leftrightarrow [x \in X \,\wedge\, (x >_X a \,\wedge\, x <_X b)]), \tag{3.373}$$
$$\forall x\,(x \in (a,b] \Leftrightarrow [x \in X \,\wedge\, (x >_X a \,\wedge\, x \leq_X b)]), \tag{3.374}$$
$$\forall x\,(x \in [a,b) \Leftrightarrow [x \in X \,\wedge\, (x \geq_X a \,\wedge\, x <_X b)]). \tag{3.375}$$

b) The set (a,b), $(a,b]$ and $[a,b)$ are subsets of X, that is,

$$(a,b) \subseteq X, \tag{3.376}$$
$$(a,b] \subseteq X, \tag{3.377}$$
$$[a,b) \subseteq X. \tag{3.378}$$

c) Furthermore, the sets (a,b), $(a,b]$ and $[a,b)$ satisfy

$$\forall x\,(x \in (a,b) \Leftrightarrow a <_X x <_X b), \tag{3.379}$$
$$\forall x\,(x \in (a,b] \Leftrightarrow a <_X x \leq_X b), \tag{3.380}$$
$$\forall x\,(x \in [a,b) \Leftrightarrow a \leq_X x <_X b). \tag{3.381}$$

a is a lower bound and b an upper bound for all of these sets (with respect to $\leq_X$).

d) The sets (a,b), $(a,b]$ and $[a,b)$ are empty if a is not less than b, i.e.

$$\neg a <_X b \Leftrightarrow (a,b) = \emptyset, \tag{3.382}$$
$$\neg a <_X b \Leftrightarrow (a,b] = \emptyset, \tag{3.383}$$
$$\neg a <_X b \Leftrightarrow [a,b) = \emptyset. \tag{3.384}$$

e) Establish the unique sets $\{(a,b) : a,b \in X\}$, $\{(a,b] : a,b \in X\}$ and $\{[a,b) : a,b \in X\}$ that satisfy

$$\forall Z\,(Z \in \{(a,b) : a,b \in X\} \Leftrightarrow \exists a,b\,(a,b \in X \,\wedge\, (a,b) = Z)), \tag{3.385}$$
$$\forall Z\,(Z \in \{(a,b] : a,b \in X\} \Leftrightarrow \exists a,b\,(a,b \in X \,\wedge\, (a,b] = Z)), \tag{3.386}$$
$$\forall Z\,(Z \in \{[a,b) : a,b \in X\} \Leftrightarrow \exists a,b\,(a,b \in X \,\wedge\, [a,b) = Z)). \tag{3.387}$$

f) The sets $\{(a,b) : a,b \in X\}$, $\{(a,b] : a,b \in X\}$ and $\{[a,b) : a,b \in X\}$ are all included in the power set of X, that is,

$$\{(a,b) : a,b \in X\} \subseteq \mathcal{P}(X), \tag{3.388}$$
$$\{(a,b] : a,b \in X\} \subseteq \mathcal{P}(X), \tag{3.389}$$
$$\{[a,b) : a,b \in X\} \subseteq \mathcal{P}(X). \tag{3.390}$$

(Hint: Proceed similarly as in the proof of Proposition 3.117.)

Definition 3.33 (Open interval, set of open intervals, left-open and right-closed interval, set of left-open and right-closed intervals, left-closed and right-open interval, set of left-closed and right-open intervals). For any partially ordered set $(X, \leq_X)$ and any elements $a,b \in X$,

(1) we call the set
$$(a,b)_X = (a,b) \tag{3.391}$$
consisting of all the elements in X strictly between a and b in the sense of
$$\forall x\,(x \in (a,b)_X \Leftrightarrow a <_X x <_X b)$$
the *open interval* from a to b (with respect to $\leq_X$). Furthermore, we call
$$\{(a,b) : a,b \in X\} \tag{3.392}$$
the *set of open intervals* in X (with respect to $\leq_X$).

(2) we call the set

$$(a,b]_X = (a,b] \tag{3.393}$$

consisting of all the elements in X satisfying

$$\forall x\,(x \in (a,b]_X \Leftrightarrow a <_X x \leq_X b)$$

the *left-open and right-closed interval* from a to b (with respect to $\leq_X$). Moreover, we call

$$\{(a,b] : a,b \in X\} \tag{3.394}$$

the *set of left-open and right-closed intervals* in X (with respect to $\leq_X$).

(3) we call the set

$$[a,b)_X = [a,b) \tag{3.395}$$

consisting of all the elements in X satisfying

$$\forall x\,(x \in [a,b)_X \Leftrightarrow a \leq_X x <_X b)$$

the *left-open and right-closed interval* from a to b (with respect to $\leq_X$). In addition, we call

$$\{[a,b) : a,b \in X\} \tag{3.396}$$

the *set of left-closed and right-open intervals* in X (with respect to $\leq_X$).

Note 3.14. We may define open intervals also more directly from a given partially ordered set $(X, <_X)$ where $<_X$ is irreflexive, instead of using the irreflexive partial ordering induced by $\leq_X$.

Corollary 3.121. *For any partially ordered set $(X, \leq_X)$ with $X \neq \emptyset$ it is true that the sets of open, of left-open and right-closed, and of left-closed and right-open intervals contain the empty set, i.e.*

$$X \neq \emptyset \;\Rightarrow\; \emptyset \in \{(a,b) : a,b \in X\}, \tag{3.397}$$
$$X \neq \emptyset \;\Rightarrow\; \emptyset \in \{(a,b] : a,b \in X\}, \tag{3.398}$$
$$X \neq \emptyset \;\Rightarrow\; \emptyset \in \{[a,b) : a,b \in X\}. \tag{3.399}$$

Proof. Letting X and $\leq_X$ be arbitrary such that $(X, \leq_X)$ is a partially ordered set and assuming $X \neq \emptyset$ to be true, there evidently exists an element in X, say $\bar{a}$. Since the induced partial ordering $<_X$ is irreflexive, the negation $\neg \bar{a} <_X \bar{a}$ holds then, so that $(\bar{a}, \bar{a}) = \emptyset$, $(\bar{a}, \bar{a}] = \emptyset$ and $[\bar{a}, \bar{a}) = \emptyset$ follow to be true with (3.382) – (3.384). Thus, the existential sentences

$$\exists a, b\,(a, b \in X \;\wedge\; (a, b) = \emptyset),$$
$$\exists a, b\,(a, b \in X \;\wedge\; (a, b] = \emptyset),$$
$$\exists a, b\,(a, b \in X \;\wedge\; [a, b) = \emptyset)$$

hold, which turn implies the desired consequents (3.397) – (3.399) with (3.385) – (3.387). Since X and $\leq_X$ were initially arbitrary sets, we may therefore conclude that the corollary holds indeed. □

Proposition 3.122. *It is true for any linearly ordered set $(X, <_X)$ that the singleton formed by an element a of X and the open interval from a to an element b of X are disjoint, i.e.*

$$\forall a, b\,(a, b \in X \Rightarrow \{a\} \cap (a, b) = \emptyset). \tag{3.400}$$

Proof. We take arbitrary sets X and $<_X$, assuming that $(X, <_X)$ is linearly ordered, and take arbitrary a and b, assuming $a, b \in X$ to hold. We may now establish the equation $\{a\} \cap (a, b) = \emptyset$ via the definition of the empty set, i.e. by proving the universal sentence

$$\forall x\,(x \notin \{a\} \cap (a, b)). \tag{3.401}$$

We let x be arbitrary, and we prove the sentence $x \notin \{a\} \cap (a, b)$ by contradiction, assuming its negation to be true. Then, the Double Negation Law gives us the true sentence $x \in \{a\} \cap (a, b)$, so that $x \in \{a\}$ and $x \in (a, b)$ follow to be both true by definition of the intersection of two sets. Here, the former yields $x = a$ with (2.169), and the latter $a <_X x$ as well as $x <_X b$ by definition of an open interval in X; we thus found $a = x$ and $a <_X x$ to be both true. Since the linear ordering $<_X$ is characterized by comparability, it is however false that $a = x$ and $a <_X x$ are simultaneously true, so that we arrived at a contradiction, and the proof of $x \notin \{a\} \cap (a, b)$ is complete. As x was arbitrary, we may therefore conclude that the universal sentence (3.401) is true, with the consequence that $\{a\} \cap (a, b) = \emptyset$. Here, a and b were arbitrary, so that the universal sentence (3.400) follows now to be also true. Finally, since X and $<_X$ were initially arbitrary as well, we may further conclude that the proposed universal sentence holds, as claimed. □

Proposition 3.123. *It is true for any partially ordered set $(X, <_X)$ that the left-closed and right-open interval from an element a to an element b can be written as the union of the open interval from a to b and the singleton formed by a if a is less than b (with respect to $<_X$), i.e.*

$$\forall a, b\,(\,a <_X b \;\Rightarrow\; [a, b) = (a, b) \cup \{a\}\,). \tag{3.402}$$

Proof. We take arbitrary sets X, $<_X$, a and b, assuming $(X, <_X)$ to be partially ordered and assuming $a <_X b$ to be true. Let us observe here that the assumed inequality can be written as $(a, b) \in <_X$; since $<_X$ is a binary relation on X, it is included in $X \times X$, so that $(a, b) \in <_X$ implies $(a, b) \in X \times X$ with the definition of a subset, and subsequently $a, b \in X$ with the definition of the Cartesian product of two sets. Thus, $[a, b)$ and (a, b) represent indeed intervals in X. We now prove the stated equation via an application of the Equality Criterion for sets, proving the equivalent universal sentence

$$\forall x\,(\,x \in [a, b) \;\Leftrightarrow\; x \in (a, b) \cup \{a\}\,). \tag{3.403}$$

We take now an arbitrary x, assuming first $x \in [a, b)$ to hold. By definition of a left-closed and right-open interval, this assumption gives us the two inequalities $a \leq_X x$ and $x <_X b$, where the former implies the disjunction $a <_X x \vee a = x$ by definition of an induced reflexive partial ordering. Let us use this disjunction to prove the disjunction $x \in (a, b) \vee x \in \{a\}$ by cases. The first case $a <_X x$ implies together with the previously established $x <_X b$, by definition of an open interval, $x \in (a, b)$, so that the disjunction to be proven also holds. In the second case $a = x$, we may write equivalently $x = a$, which implies then $x \in \{a\}$ with (2.169), so that the disjunction $x \in (a, b) \vee x \in \{a\}$ follows to be true again. Having thus completed the proof by cases, we may infer from the truth of that disjunction the truth of the desired consequent $x \in (a, b) \cup \{a\}$ by means of the definition of the union of two sets, and therefore the truth of the first part ('$\Rightarrow$') of the equivalence in (3.403).

Regarding the second part ('$\Leftarrow$'), we assume conversely $x \in (a, b) \cup \{a\}$ to be true, giving the true disjunction $x \in (a, b) \vee x \in \{a\}$ (using again definition of the union of two sets). We may use this disjunction to prove $x \in [a, b)$ by cases. On the one hand, if $x \in (a, b)$ is true, so that the inequalities $a <_X x$ and $x <_X b$ hold (by definition of an open interval), we now see that the former inequality yields the true disjunction $a <_X x \vee a = x$. This disjunction in turn gives $a \leq_X x$ (by definition of an induced reflexive partial ordering), which further implies – in connection with the previously obtained $x <_X b$, the desired consequent $x \in [a, b)$ (by definition of a left-closed and right-open interval). On the other hand, if $x \in \{a\}$ is true, so that $x = a$ holds according to (2.169), we obtain from the initial assumption $a <_X b$ via substitution $x <_X b$. Furthermore, writing the preceding equation as $a = x$, the disjunction $a <_X x \vee a = x$ is then true again, with the previously inferred consequence that $a \leq_X x$ holds. The conjunction of the two findings $a \leq_X x$ and $x <_X b$ gives us now the desired consequent $x \in [a, b)$ also in the second case, so that the proof of the second part of the equivalence in (3.403) is complete. Because

x is arbitrary, the universal sentence (3.403) follows to be true, which in turn implies the truth of the equation in (3.402). As the sets X, $\leq_X$, a and b were all arbitrary, we may therefore conclude that the proposition is true. □

Exercise 3.54. Show for any partially ordered set $(X, \leq_X)$ that

a) the left-open and right-closed interval from an element a to an element b can be written as the union of the open interval from a to b and the singleton formed by b if a is less than b (with respect to $\leq_X$), i.e.

$$\forall a, b\,(\, a <_X b \Rightarrow (a, b] = (a, b) \cup \{b\}\,). \tag{3.404}$$

b) the closed interval from an element a to an element b can be written as the union of the left-closed, right-open interval from a to b and the singleton formed by b if a is less than or equal to b (with respect to $\leq_X$), i.e.

$$\forall a, b\,(\, a \leq_X b \Rightarrow [a, b] = [a, b) \cup \{b\}\,). \tag{3.405}$$

(Hint: Proceed in analogy to the proof of Proposition 3.123.)

Corollary 3.124. *It is true for any linearly ordered set $(X, <_X)$ that the singleton formed by an element a can be written as the difference of the left-closed, right-open interval from a to an element b and the open interval from a to b if a is less than b (with respect to $<_X$), i.e.*

$$\forall a, b\,(\, a <_X b \Rightarrow \{a\} = [a, b) \setminus (a, b)\,). \tag{3.406}$$

Proof. Letting X, $<_X$, a and b be arbitrary, assuming $(X, <_X)$ to be linearly ordered and assuming $a <_X b$ to hold (where $a, b \in X$ is then true), we obtain for the union C of $\{a\}$ and (a, b)

$$C = \{a\} \cup (a, b) = (a, b) \cup \{a\} = [a, b)$$

with the Commutative Law for the union of two sets and with (3.402). Furthermore, we obtain

$$\{a\} \cap (a, b) = \emptyset$$

with (3.400). We may therefore apply (2.262) to infer from these findings the truth of

$$\{a\} = C \setminus (a, b) = [a, b) \setminus (a, b),$$

which equations yield the desired consequent of the implication in (3.406). Because X, $<_X$, a and b were initially arbitrary, the proposed universal sentence follows then to be true. □

In the following, we explore some set-theoretical interactions of, respectively, two open and two left-closed and right-open intervals.

Proposition 3.125. *The following sentences are true for any partially ordered set* $(X, \leq_X)$ *and any elements* $a_1, a_2, b_1, b_2 \in X$*.*

a) Concerning the inclusion of two open intervals,

$$(a_2 \leq_X a_1 \,\wedge\, b_1 \leq_X b_2) \Rightarrow (a_1, b_1) \subseteq (a_2, b_2). \tag{3.407}$$

b) Concerning the intersection of two open intervals,

$$(a_1, b_1) \cap (a_2, b_2) = (a_1, b_2) \cap (a_2, b_1). \tag{3.408}$$

c) Concerning the disjointness of two open intervals,

$$(\neg a_2 <_X b_1 \,\vee\, \neg a_1 <_X b_2) \Rightarrow (a_1, b_1) \cap (a_2, b_2) = \emptyset. \tag{3.409}$$

Proof. Letting X, $\leq_X$, a_1, a_2, b_1 and b_2 be arbitrary such that $(X, \leq_X)$ is a partially ordered set and such that $a_1, a_2, b_1, b_2 \in X$ holds, we assume concerning a) the antecedent $a_2 \leq_X a_1 \,\wedge\, b_1 \leq_X b_2$ to be true. To show that this implies the inclusion $(a_1, b_1) \subseteq (a_2, b_2)$, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall x \, (x \in (a_1, b_1) \Rightarrow x \in (a_2, b_2)).$$

For this purpose, we let $x \in (a_1, b_1)$ be arbitrary and show that this implies $x \in (a_2, b_2)$. The assumption $x \in (a_1, b_1)$ means by definition of an open interval that $a_1 <_X x$ and $x <_X b_1$ are true. On the one hand, the two assumed inequalities $a_2 \leq_X a_1$ and $a_1 <_X x$ imply $a_2 <_X x$ with the Transitivity Formula for $\leq$ and $<$. On the other hand, the other two assumed inequalities $x <_X b_1$ and $b_1 \leq_X b_2$ imply $x < b_2$ with the Transitivity Formula for $<$ and $\leq$. Then, since $a_2 <_X x$ and $x <_X b_2$ are simultaneously true, we obtain $x \in (a_2, b_2)$ by definition of an open interval, as desired. As x was arbitrary, we may therefore infer from this finding the truth of the inclusion $(a_1, b_1) \subseteq (a_2, b_2)$, proving (3.407).

Concerning b), we obtain for an arbitrary x the true equivalences

$$\begin{aligned}
x \in (a_1, b_1) \cap (a_2, b_2) \;&\Leftrightarrow\; x \in (a_1, b_1) \,\wedge\, x \in (a_2, b_2) \\
&\Leftrightarrow\; (a_1 <_X x \,\wedge\, x <_X b_1) \,\wedge\, (a_2 <_X x \,\wedge\, x <_X b_2) \\
&\Leftrightarrow\; (a_1 <_X x \,\wedge\, x <_X b_2) \,\wedge\, (a_2 <_X x \,\wedge\, x <_X b_1) \\
&\Leftrightarrow\; x \in (a_1, b_2) \,\wedge\, x \in (a_2, b_1) \\
&\Leftrightarrow\; x \in (a_1, b_2) \cap (a_2, b_1)
\end{aligned}$$

by applying the definition of the intersection of two sets, the definition of an open interval, the Associative and Commutative Law for the conjunction, again the definition of an open interval, and finally again the definition of the intersection of two sets. As x is arbitrary, we may infer from the truth of these equivalences the truth of the equation (3.408) with the Equality Criterion for sets.

For the proof of c) we assume $\neg a_2 <_X b_1 \vee \neg a_1 <_X b_2$ and prove the desired consequent $(a_1, b_1) \cap (a_2, b_2) = \emptyset$ by cases. The first case $\neg a_2 <_X b_1$ implies $(a_2, b_1) = \emptyset$ with (3.382), so that we obtain

$$(a_1, b_1) \cap (a_2, b_2) = (a_1, b_2) \cap (a_2, b_1) = (a_1, b_2) \cap \emptyset = \emptyset$$

by applying b), substitution and (2.62). Using exactly the same arguments, the second case $\neg a_1 <_X b_2$ gives $(a_1, b_2) = \emptyset$ and then

$$(a_1, b_1) \cap (a_2, b_2) = (a_1, b_2) \cap (a_2, b_1) = \emptyset \cap (a_2, b_1) = \emptyset,$$

completing the proof by cases.

Because X, $\leq_X$, a_1, a_2, b_1 and b_2 were initially also arbitrary, we may then further conclude that the proposition is true. □

Exercise 3.55. Establish the following sentences for any partially ordered set $(X, \leq_X)$ and any elements $a_1, a_2, b_1, b_2 \in X$.

a) Concerning the inclusion of two left-closed and right-open intervals,

$$(a_2 \leq_X a_1 \wedge b_1 \leq_X b_2) \Rightarrow [a_1, b_1) \subseteq [a_2, b_2). \tag{3.410}$$

(Hint: Apply the Transitivity Formula for $<$ and $\leq$.)

b) Concerning the intersection of two left-closed and right-open intervals,

$$[a_1, b_1) \cap [a_2, b_2) = [a_1, b_2) \cap [a_2, b_1). \tag{3.411}$$

(Hint: Use the Equality Criterion for sets in connection with Theorem 1.12 & 1.11.)

c) Concerning the disjointness of two left-closed and right-open intervals,

$$(\neg a_2 <_X b_1 \vee \neg a_1 <_X b_2) \Rightarrow [a_1, b_1) \cap [a_2, b_2) = \emptyset. \tag{3.412}$$

(Hint: Use b) and (2.62).)

We now establish a rule for left-closed and right-open intervals that requires the partial ordering to be linear/total.

Proposition 3.126. *The following universal sentence holds for any linearly ordered set* $(X, <_X)$.

$$\forall a, b, c\,([a, b, c \in X \;\wedge\; a \leq_X b \leq_X c] \Rightarrow [a, b) \cup [b, c) = [a, c)). \qquad (3.413)$$

Proof. We let X, $\leq_X$, a, b and c be arbitrary assuming that $(X, \leq_X)$ is partially ordered, that $a, b, c \in X$ holds, and assuming moreover the inequalities $a \leq_X b \leq_X c$ to be true. We now prove the stated equation by applying the Equality Criterion for sets, by verifying the universal sentence

$$\forall x\,(x \in [a, b) \cup [b, c) \Leftrightarrow x \in [a, c)). \qquad (3.414)$$

We let x be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $x \in [a, b) \cup [b, c)$ to be true. Therefore, the disjunction $x \in [a, b) \vee x \in [b, c)$ is true by definition of the union of two sets. We now use this true disjunction to prove the desired consequent $x \in [a, c)$ by cases. In case $x \in [a, b)$ holds, we have $a \leq_X x$ and $x <_X b$ according to the definition of a left-closed and right-open interval. The latter implies now with the initial assumption $b \leq_X c$ because of the Transitivity Formula for $<$ and $\leq$ that $x <_X c$ holds. Together with the previously established $a \leq_X x$, this in turn implies $x \in [a, c)$, as desired. In the other case that $x \in [b, c)$ holds, i.e. $b \leq_X x$ and $x <_X c$, the former implies with the initial assumption $a \leq_X b$ and the transitivity of the induced total ordering $\leq_X$ that $a \leq_X x$ is true. Thus, $a \leq_X x$ and $x <_X c$ are both true, which means again $x \in [a, c)$, completing the proof by cases, and then also the proof of the first part of the equivalence.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume $x \in [a, c)$ to be true, i.e. $a \leq_X x$ and $x <_X c$. Noting that the disjunction $x <_X b \vee \neg x <_X b$ is true according to the Law of the Excluded Middle, we now prove $x \in [a, b) \vee x \in [b, c)$ by cases. The first case $x <_X b$ implies together with $a \leq_X x$ that $x \in [a, b)$ holds, which further implies the truth of the disjunction $x \in [a, b) \vee x \in [b, c)$. The other case $\neg x <_X b$ gives with the Negation Formula for $<$ the inequality $b \leq_X x$ and therefore – in view of $x <_X c$ – the truth of $x \in [b, c)$. Then, the disjunction $x \in [a, b) \vee x \in [b, c)$ is true again, which thus holds in any case. Consequently, we obtain by definition of the union of two sets $x \in [a, b) \cup [b, c)$, which finding completes the proof of the equivalence (3.414).

As x is arbitrary, we may infer from the truth of that equivalence the truth of the equation in (3.413). Since a, b, c and also X and $<_X$ were arbitrary, we may therefore conclude that the proposition is true. □

The following sentence shows that an open interval may, under certain conditions, be constructed via the intersection of the other two other types of intervals considered in Definition 3.33.

Proposition 3.127. *Show for any partially ordered set $(X, <_X)$ and any elements $a_1, b_1, a_2, b_2 \in X$ satisfying $a_1 \leq_X a_2$ as well as $b_1 \leq_X b_2$ that the intersection of the left-closed and right-open interval from a_1 to b_1 and the left-open and right-closed interval from a_2 to b_2 is the open interval from a_2 to b_1, i.e.*

$$[a_1 \leq_X a_2 \wedge b_1 \leq_X b_2] \Rightarrow [a_1, b_1) \cap (a_2, b_2] = (a_2, b_1)\,). \tag{3.415}$$

Proof. We let X, $<_X$, a_1, b_1, a_2 and b_2 be arbitrary such that $(X, <_X)$ is partially ordered, such that $a_1, b_1, a_2, b_2 \in X$ is true, and such that the inequalities $a_1 \leq_X a_2 \wedge b_1 \leq_X b_2$ hold. We now apply the Equality Criterion for sets to establish the stated equation. To do this, we prove the universal sentence

$$\forall x\,(\, x \in [a_1, b_1) \cap (a_2, b_2] \Leftrightarrow x \in (a_2, b_1)\,), \tag{3.416}$$

letting x be arbitrary and assuming first $x \in [a_1, b_1) \cap (a_2, b_2]$ to be true. Therefore, we obtain with the definition of the intersection of two sets $x \in [a_1, b_1)$ and $x \in (a_2, b_2]$, and then with the definition of a left-closed and right-open as well as with the definition of a left-open and right-closed interval the inequalities $a_1 \leq_X x$, $x <_X b_1$, $a_2 <_X x$ and $x \leq_X b_2$. We thus have $a_2 <_X x <_X b_1$, so that $x \in (a_2, b_1)$ follows to be true by definition of an open interval, as desired. We now conversely assume $x \in (a_2, b_1)$ to be true, so that $a_2 <_X x$ and $x <_X b_1$ hold (by definition of an open interval). These two inequalities clearly imply the truth of the two disjunctions $a_2 <_X x \vee a_2 = x$ and $x <_X b_1 \vee x = b_1$ and therefore the truth of the two inequalities $a_2 \leq_X x$ and $x \leq_X b_1$ (using the definition of an induced reflexive partial ordering). Here, the conjunction of the assumed inequality $a_1 \leq_X a_2$ and $a_2 \leq_X x$ implies $a_1 \leq_X x$ with the transitivity of the induced reflexive partial ordering $\leq_X$. For the same reason, the conjunction of $x \leq_X b_1$ the other assumed inequality $b_1 \leq_X b_2$ gives $x \leq_X b_2$. The previous findings evidently allow us to form the conjunctions

$$(a_1 \leq_X x \wedge x <_X b_1) \wedge (a_2 <_X x \wedge x \leq_X b_2),$$

with the consequence that $x \in [a_1, b_1)$ and $x \in (a_2, b_2]$ are both true. Therefore, x is in the intersection of these two intervals, so that the second part of the equivalence in (3.416) also holds. As x is arbitrary, we may now infer from the truth of that equivalence the truth of the universal sentence (3.416) and consequently the truth of the equation $[a_1, b_1) \cap (a_2, b_2] = (a_2, b_1)$. This proves the implication (3.415), and since X, $<_X$, a_1, b_1, a_2 and b_2 were initially arbitrary, we may then further conclude that the proposed universal sentence holds. □

In the following, we establish four more basic types of intervals, which will be shown to have diverse relationships to the previously introduced intervals.

Exercise 3.56. Prove the following sentences for any partially ordered set $(X, \leq_X)$ and for any elements $a, b \in X$.

a) There exist unique sets $(a, +\infty)$, $[a, +\infty)$, $(-\infty, b)$ and $(-\infty, b]$ such that

$$\forall x\,(x \in (a, +\infty) \Leftrightarrow [x \in X \,\wedge\, x >_X a]), \tag{3.417}$$
$$\forall x\,(x \in [a, +\infty) \Leftrightarrow [x \in X \,\wedge\, x \geq_X a]), \tag{3.418}$$
$$\forall x\,(x \in (-\infty, b) \Leftrightarrow [x \in X \,\wedge\, x <_X b]), \tag{3.419}$$
$$\forall x\,(x \in (-\infty, b] \Leftrightarrow [x \in X \,\wedge\, x \leq_X b]). \tag{3.420}$$

b) The sets $(a, +\infty)$, $[a, +\infty)$, $(-\infty, b)$ and $(-\infty, b]$ are included in X, i.e.

$$(a, +\infty) \subseteq X, \tag{3.421}$$
$$[a, +\infty) \subseteq X, \tag{3.422}$$
$$(-\infty, b) \subseteq X, \tag{3.423}$$
$$(-\infty, b] \subseteq X. \tag{3.424}$$

c) Furthermore, the sets $(a, +\infty)$, $[a, +\infty)$, $(-\infty, b)$ and $(-\infty, b]$ satisfy

$$\forall x\,(x \in (a, +\infty) \Leftrightarrow a <_X x), \tag{3.425}$$
$$\forall x\,(x \in [a, +\infty) \Leftrightarrow a \leq_X x), \tag{3.426}$$
$$\forall x\,(x \in (-\infty, b) \Leftrightarrow x <_X b), \tag{3.427}$$
$$\forall x\,(x \in (-\infty, b] \Leftrightarrow x \leq_X b). \tag{3.428}$$

d) The sets $[a, +\infty)$ and $(-\infty, b]$ are nonempty, i.e.

$$[a, +\infty) \neq \emptyset, \tag{3.429}$$
$$(-\infty, b] \neq \emptyset. \tag{3.430}$$

(Hint: Use (2.42) and the reflexivity of $\leq_X$.)

e) Establish the unique sets $\{(a, +\infty) : a \in X\}$, $\{[a, +\infty) : a \in X\}$, $\{(-\infty, b) : b \in X\}$ and $\{(-\infty, b] : b \in X\}$ that satisfy

$$\forall Z\,(Z \in \{(a, +\infty) : a \in X\} \Leftrightarrow \exists a\,(a \in X \,\wedge\, (a, +\infty) = Z)), \tag{3.431}$$
$$\forall Z\,(Z \in \{[a, +\infty) : a \in X\} \Leftrightarrow \exists a\,(a \in X \,\wedge\, [a, +\infty) = Z)), \tag{3.432}$$
$$\forall Z\,(Z \in \{(-\infty, b) : b \in X\} \Leftrightarrow \exists b\,(b \in X \,\wedge\, (-\infty, b) = Z)), \tag{3.433}$$
$$\forall Z\,(Z \in \{(-\infty, b] : b \in X\} \Leftrightarrow \exists b\,(b \in X \,\wedge\, (-\infty, b] = Z)). \tag{3.434}$$

f) All of the sets in e) are included in the power set of X, that is,

$$\{(a,+\infty) : a \in X\} \subseteq \mathcal{P}(X), \tag{3.435}$$
$$\{[a,+\infty) : a \in X\} \subseteq \mathcal{P}(X), \tag{3.436}$$
$$\{(-\infty,b) : b \in X\} \subseteq \mathcal{P}(X), \tag{3.437}$$
$$\{(-\infty,b] : b \in X\} \subseteq \mathcal{P}(X). \tag{3.438}$$

Definition 3.34 ((Set of) open and unbounded & left-closed and right-unbounded & open and left-unbounded interval & left-unbounded and right-closed intervals). For any partially ordered set $(X,\leq_X)$ and any elements $a,b \in X$,

(1) we call the set
$$(a,+\infty)_X = (a,+\infty) \tag{3.439}$$
consisting of all the elements in X that are greater than a the *open and right-unbounded interval* beginning in a (with respect to $\leq_X$). Furthermore, we call
$$\{(a,+\infty) : a \in X\} \tag{3.440}$$
the *set of open and right-unbounded intervals* in X (w.r.t. $\leq_X$).

(2) we call the set
$$[a,+\infty)_X = [a,+\infty) \tag{3.441}$$
consisting of all the elements in X that are greater than or equal to a the *left-closed and right-unbounded interval* beginning in a (w.r.t. $\leq_X$). Moreover, we call
$$\{[a,+\infty) : a \in X\} \tag{3.442}$$
the *set of left-closed and right-unbounded intervals* in X (w.r.t. $\leq_X$).

(3) we call the set
$$(-\infty,b)_X = (-\infty,b) \tag{3.443}$$
consisting of all the elements in X that are less than b the *open and left-unbounded interval* up to b (w.r.t. $\leq_X$). In addition, we call
$$\{(-\infty,b) : b \in X\} \tag{3.444}$$
the *set of open and left-unbounded intervals* in X (w.r.t. $\leq_X$).

(4) we call the set

$$(-\infty, b]_X = (-\infty, b] \tag{3.445}$$

consisting of all the elements in X that are less than or equal to b the *left-unbounded and right-closed interval* up to b (w.r.t. $\leq_X$), and

$$\{(-\infty, b] : b \in X\} \tag{3.446}$$

the *set of left-unbounded and right-closed intervals* in X (w.r.t. $\leq_X$).

Proposition 3.128. *It is true for any linearly ordered set $(X, <_X)$ that the open and left-unbounded interval ending in any element b of X is the complement (with respect to X) of the left-closed and right-unbounded interval beginning in b, that is,*

$$\forall b\,(b \in X \Rightarrow (-\infty, b) = [b, +\infty)^c). \tag{3.447}$$

Proof. We let X, $<_X$ and b be arbitrary, assuming $<_X$ to be a linear ordering of X (inducing thus the total ordering $\leq_X$ of X) and assuming b to be contained in X. Let us now apply the Equality Criterion for sets to prove $(-\infty, b) = [b, +\infty)^c$. We then need to establish the truth of the universal sentence

$$\forall x\,(x \in (-\infty, b) \Leftrightarrow x \in [b, +\infty)^c). \tag{3.448}$$

For this purpose, we let x be arbitrary and observe the truth of the equivalences

$$\begin{aligned} x \in (-\infty, b) &\Leftrightarrow x \in X \wedge x <_X b \\ &\Leftrightarrow x \in X \wedge \neg b \leq_X x \\ &\Leftrightarrow x \in X \wedge \neg x \in [b, +\infty) \\ &\Leftrightarrow x \in X \setminus [b, +\infty) \\ &\Leftrightarrow x \in [b, +\infty)^c \end{aligned}$$

in light of (3.419), the Negation Formula for $\leq$, (3.426), the definition of a set difference and the definition of a complement (with respect to X) in connection with (3.422). Since x is arbitrary, we may infer from the truth of the resulting equivalence $x \in (-\infty, b) \Leftrightarrow x \in [b, +\infty)^c$ the truth of (3.448), and therefore the truth of the equation (3.447). Because b, X and $<_X$ were arbitrary, the proposition follows then to be true. □

Corollary 3.129. *It is true for any linearly ordered set $(X, <_X)$ that the left-closed and right-unbounded interval beginning in any element a of X is the complement of the open and left-unbounded interval ending in a, i.e.*

$$\forall a\,(a \in X \Rightarrow [a, +\infty) = (-\infty, a)^c). \tag{3.449}$$

Proof. Letting $(X, <_X)$ be an arbitrary linearly ordered set and a an arbitrary element of X, we obtain

$$[a, +\infty) = ([a, +\infty)^c)^c = (-\infty, a)^c$$

by applying (2.136) and substitution based on (3.447). Then, the resulting equation $[a, +\infty) = (-\infty, a)^c$ is universally true since a and $(X, <_X)$ were arbitrary. $\square$

Exercise 3.57. Show for any linearly ordered set $(X, <_X)$ that

a) the left-unbounded and right-closed interval ending in any element b of X is the complement of the open and right-unbounded interval beginning in b, i.e.

$$\forall b\,(b \in X \Rightarrow (-\infty, b] = (b, +\infty)^c). \tag{3.450}$$

b) the open and right-unbounded interval beginning in any element a of X is the complement of the left-unbounded right-closed interval ending in a, i.e.

$$\forall a\,(a \in X \Rightarrow (a, +\infty) = (-\infty, a]^c). \tag{3.451}$$

Proposition 3.130. *It is true for any partially ordered set $(X, \leq_X)$ that the left-closed, right-unbounded interval beginning in an element a of X can be written as the union of the open, right-unbounded interval beginning in a and the singleton formed by a, i.e.*

$$\forall a\,(a \in X \;\Rightarrow\; [a, +\infty) = (a, +\infty) \cup \{a\}). \tag{3.452}$$

Proof. We take arbitrary X, $\leq_X$ and a such that $(X, \leq_X)$ is a partially ordered set and such that a is an element of X. Letting then also x be arbitrary, we obtain the true equivalences

$$\begin{aligned} x \in [a, +\infty) \;&\Leftrightarrow\; a \leq_X x \\ &\Leftrightarrow\; a <_X x \,\vee\, a = x \\ &\Leftrightarrow\; a <_X x \,\vee\, x = a \\ &\Leftrightarrow\; x \in (a, +\infty) \,\vee\, x \in \{a\} \\ &\Leftrightarrow\; x \in (a, +\infty) \,\cup\, \{a\} \end{aligned}$$

by applying the definition of a left-closed and right-unbounded interval, the definition of an induced irreflexive partial ordering, (1.96), the definition of an open, right-unbounded interval together with (2.169), and finally the definition of a union of two sets. Because x is arbitrary, we may now infer from these equivalences by means of the Equality Criterion for sets the truth of the desired equation in (3.452). Since a, X and $\leq_X$ were arbitrary, we may therefore conclude that the proposed universal sentence holds. $\square$

Exercise 3.58. Prove for any partially ordered set $(X, \leq_X)$ that the left-unbounded, right-closed interval ending in an element b of X can be written as the union of the open, left-unbounded interval ending in b and the singleton formed by b, i.e.

$$\forall b\,(b \in X \;\Rightarrow\; (-\infty, b] = (-\infty, b) \cup \{b\}). \tag{3.453}$$

Proposition 3.131. *The following implication is true for any partially ordered set* $(X, \leq_X)$ *and any elements* $a_1, b_1, a_2 \in X$.

$$a_2 \leq_X a_1 \;\Rightarrow\; [a_1, b_1) \subseteq [a_2, +\infty). \tag{3.454}$$

Proof. We let X and $\leq_X$ be arbitrary such that $(X, \leq_X)$ is partially ordered, and we let a_1, b_1 and a_2 also be arbitrary in X. To prove the implication, we assume $a_2 \leq_X a_1$ and establish the desired inclusion $[a_1, b_1) \subseteq [a_2, +\infty)$ by applying the definition of a subset, i.e. by verifying

$$\forall x\,(x \in [a_1, b_1) \Rightarrow x \in [a_2, +\infty)). \tag{3.455}$$

To do this, we let x be arbitrary and assume $x \in [a_1, b_1)$ to be true, so that the inequalities $a_1 \leq_X x$ and $x <_X b_1$ are true by definition of a left-closed and right-open interval. We now see that the assumption $a_2 \leq_X a_1$ and the previously obtained $a_1 \leq_X x$ imply $a_2 \leq_X x$ with the transitivity of the partial ordering $\leq_X$. Consequently, $x \in [a_2, +\infty)$ holds by definition of a left-closed and right-unbounded interval, which was to be proven. Since x is arbitrary, we may therefore conclude that the universal sentence (3.455) holds, which then implies the truth of the inclusion $[a_1, b_1) \subseteq [a_2, +\infty)$, proving the implication (3.454). As X, $\leq_X$, a_1, b_1 and a_2 were arbitrary, we may now further conclude that the proposed universal sentence is true. $\square$

Exercise 3.59. Verify the following implication for any partially ordered set $(X, \leq_X)$ and any elements $a_1, b_1, b_2 \in X$.

$$b_1 \leq_X b_2 \;\Rightarrow\; [a_1, b_1) \subseteq (-\infty, b_2). \tag{3.456}$$

(Hint: Proceed similarly as in the proof of Proposition 3.131, using now the Transitivity Formula for $<$ and $\leq$.)

Proposition 3.132. *It is true for any linearly ordered set $(X, <_X)$ that the open and left-unbounded interval up to an $a \in X$ is included in the open and left-unbounded interval up to a $b \in X$ iff a is less than or equal to b, that is,*

$$\forall a, b\,(a, b \in X \Rightarrow [(-\infty, a) \subseteq (-\infty, b) \Leftrightarrow a \leq_X b]). \tag{3.457}$$

Proof. Letting $(X, <_X)$ be an arbitrary linearly ordered set and a, b arbitrary constants in X, we prove the first part ('$\Rightarrow$') of the equivalence by contradiction, assuming the inclusion $(-\infty, a) \subseteq (-\infty, b)$ and the negation $\neg a \leq_X b$. By definition of a subset, we thus have

$$\forall x\,(x \in (-\infty, a) \Rightarrow x \in (-\infty, b)), \tag{3.458}$$

and the negation implies $b <_X a$ with the Negation Formula for $\leq$. The latter inequality implies $b \in (-\infty, a)$ by definition of an open and left-unbounded interval, so that $b \in (-\infty, b)$ follows to be true with (3.458). Consequently, $b <_X b$ holds by definition of an open and left-unbounded interval, in contradiction to the fact that $\neg b <_X b$ is true since the linear ordering $<_X$ is irreflexive by definition. Thus, the proof of the first implication is complete. To establish the second part ('$\Leftarrow$') of the equivalence, we assume $a \leq_X b$ to be true, and we show that the inclusion $(-\infty, a) \subseteq (-\infty, b)$ also holds. For this purpose, we prove the universal sentence (3.458), letting $x \in (-\infty, a)$ be arbitrary. Since this implies $x <_X a$ $[\leq_X b]$ with the definition of an open and left-unbounded interval, we obtain with the Transitivity Formula for $<$ and $\leq$ the true inequality $x <_X b$, which evidently implies $x \in (-\infty, b)$, as desired. As x was arbitrary, we may conclude that the universal sentence (3.458) is true, so that the inclusion $(-\infty, a) \subseteq (-\infty, b)$ holds indeed. Thus, the proof of the equivalence in (3.457) is complete, and since a and b were arbitrary, the universal sentence (3.457) follows to be true, too. Initially, $(X, <_X)$ was arbitrary, so that we may finally conclude that the stated proposition is true. □

Proposition 3.133. *It is true for any partially ordered set $(X, <_X)$ that the open, left-unbounded interval up to an element $b \in X$ and the open, right-unbounded interval beginning at an element $a \in X$ are disjoint if a is not less than b, i.e.*

$$\forall a, b\,([a, b \in X \wedge \neg a <_X b] \;\Rightarrow\; (-\infty, b) \cap (a, +\infty) = \emptyset). \tag{3.459}$$

Proof. We take arbitrary X, $\leq_X$, a and b, assume that $(X, <_X)$ is a partially ordered set, and we assume $a, b \in X$ as well as $\neg a <_X b$ to be true. Next, we establish the universal sentence

$$\forall y\,(y \notin (-\infty, b) \cap (a, +\infty)), \tag{3.460}$$

letting y be arbitrary. Let us now prove $y \notin (-\infty, b) \cap (a, +\infty)$ by contradiction, assuming its negation to be true. Then, $y \in (-\infty, b) \cap (a, +\infty)$ follows to be true with the Double Negation Law, and the definition of the intersection of two sets gives $y \in (-\infty, b)$ as well as $y \in (a, +\infty)$. By definition of open and left-/right-unbounded intervals, we therefore have the inequalities $y <_X b$ and $a <_X y$. Consequently, the transitivity of the partial ordering $<_X$ yields $a <_X b$, in evident contradiction to the the assumed negation $\neg a <_X b$. This finding completes the proof of $y \notin (-\infty, b) \cap (a, +\infty)$ by contradiction, and since y is arbitrary, we may therefore conclude that the universal sentence (3.460) is true. We then obtain $(-\infty, b) \cap (a, +\infty) = \emptyset$ with the definition of the empty set, proving the implication in (3.459). As X, $\leq_X$, a and b were initially arbitrary, we may now finally conclude that the proposition holds, as claimed. □

Proposition 3.134. *It is true for any partially ordered set* $(X, <_X)$ *that the open interval from an element* $a \in X$ *to an element* $b \in X$ *can be written as the intersection of the open, left-unbounded interval ending in* b *and the open, right-unbounded interval beginning in* a*, i.e.*

$$(a, b) = (-\infty, b) \cap (a, +\infty). \tag{3.461}$$

Proof. Letting X, $\leq_X$, a and b be arbitrary, assuming $(X, <_X)$ to be partially ordered, assuming furthermore a and b to be elements of X, and letting now also y be arbitrary, we obtain the true equivalences

$$\begin{aligned} y \in (a, b) \;&\Leftrightarrow\; a <_X y <_X b \\ &\Leftrightarrow\; y <_X b \,\wedge\, a <_X y \\ &\Leftrightarrow\; y \in (-\infty, b) \,\wedge\, y \in (a, +\infty) \\ &\Leftrightarrow\; y \in (-\infty, b) \cap (a, +\infty) \end{aligned}$$

by applying the definition of an open interval, the Commutative Law for the conjunction, the definition of an open and left-unbounded interval together with the definition of an open and right-unbounded interval, and finally the definition of the intersection of two sets. Since y is arbitrary, we may then infer from the preceding equivalences the truth of the equation (3.461) because of the Equality Criterion for sets. Because X, $\leq_X$, a and b are also arbitrary, the proposition follows to true. □

Proposition 3.135. *It is true for any for any linearly ordered set* $(X, <_X)$ *and for any elements* $a, b \in X$ *that the complement of the closed interval from* a *to* b *(with respect to* X*) can be written as the union of the open, left-unbounded interval ending in* a *and the open, right-unbounded interval beginning in* b*, i.e.*

$$[a, b]^c = (-\infty, a) \cup (b, +\infty). \tag{3.462}$$

Proof. We take arbitrary X, $<_X$, a and b, assume that $(X, <_X)$ is a linearly ordered set, and we assume that $a, b \in X$ holds. Letting now y be arbitrary, we obtain the equivalences

$$\begin{aligned} y \in [a,b]^c &\Leftrightarrow y \in X \setminus [a,b] \\ &\Leftrightarrow y \in X \wedge \neg y \in [a,b] \\ &\Leftrightarrow y \in X \wedge \neg(a \leq_X y \wedge y \leq_X b) \\ &\Leftrightarrow y \in X \wedge (\neg a \leq_X y \vee \neg y \leq_X b) \\ &\Leftrightarrow y \in X \wedge (y <_X a \vee b <_X y) \\ &\Leftrightarrow (y \in X \wedge y <_X a) \vee (y \in X \wedge b <_X y) \\ &\Leftrightarrow y \in (-\infty, a) \vee y \in (b, +\infty) \\ &\Leftrightarrow y \in (-\infty, a) \cup (b, +\infty) \end{aligned}$$

using the definition of a complement based on the inclusion (3.352), the definition of a set difference, the definition of a closed interval (in X), De Morgan's Law for the conjunction, the Negation Formulas for $\leq$ and $<$, the Distributive Law for the conjunction, the definitions of an open, left-/right-unbounded interval (in X), and the definition of the union of two sets. Since y is arbitrary, we may infer from the truth of these equivalences the truth of the equation (3.462). Because X, $<_X$, a and b were initially also arbitrary, we may therefore conclude that the proposed universal sentence is true. $\square$

Exercise 3.60. Show that the following equation holds for any for any linearly ordered set $(X, <_X)$ and for any elements $a, b \in X$.

$$[a,b)^c = (-\infty, a) \cup [b, +\infty) \tag{3.463}$$
$$(a,b]^c = (-\infty, a] \cup (b, +\infty) \tag{3.464}$$

(Hint: Proceed in analogy to the proof of Proposition 3.135.).

Exercise 3.61. Prove the following equation for any partially ordered set $(X, \leq_X)$ and any elements $a_1, a_2, b_1, b_2 \in X$.

$$[a_1, b_1) \setminus [a_2, b_2) = (\, [a_1, a_2) \cap (-\infty, b_1)\,) \cup (\, [b_2, b_1) \cap [a_1, +\infty)\,)\,. \tag{3.465}$$

(Hint: Use the Equality Criterion for sets in connection with (2.138), (3.378), Definition 2.8, (3.463), Definition 2.19, (1.44), (1.39) and (1.36).)

Proposition 3.136. *It is true for any linearly ordered set $(X, <_X)$ that the left-closed and right-open interval from an element a of X to an element b of X can be written as the difference of the open, left-unbounded interval ending in b and the open, left-unbounded interval ending in a, i.e.*

$$\forall a, b\,(\, a, b \in X \Rightarrow [a,b) = (-\infty, b) \setminus (-\infty, a)\,). \tag{3.466}$$

Proof. Letting X, $<_X$, a and b be arbitrary such that $(X, <_X)$ is a linearly ordered set and such that a and b are elements in X, we may apply the Equality Criterion for sets to establish $[a, b) = (-\infty, b) \setminus (-\infty, a)$, by proving the corresponding universal sentence

$$\forall x\,(\,x \in [a, b) \Leftrightarrow x \in (-\infty, b) \setminus (-\infty, a)\,). \tag{3.467}$$

We let now also x be arbitrary, so that we obtain the true equivalences

$$\begin{aligned} x \in [a, b) &\Leftrightarrow a \leq_X x \wedge x <_X b \\ &\Leftrightarrow x <_X b \wedge a \leq_X x \\ &\Leftrightarrow x <_X b \wedge \neg x <_X a \\ &\Leftrightarrow x \in (-\infty, b) \wedge \neg x \in (-\infty, a) \\ &\Leftrightarrow x \in (-\infty, b) \setminus (-\infty, a) \end{aligned}$$

by applying the definition of a left-closed and right-open interval, the Commutative Law for the conjunction, the Negation Formula for $<$, the definition of an open and left-unbounded interval, and finally the definition of a set difference. Since x is arbitrary, we may infer from the resulting equivalence $x \in [a, b) \Leftrightarrow x \in (-\infty, b) \setminus (-\infty, a)$ the truth of the equation $[a, b) = (-\infty, b) \setminus (-\infty, a)$. Here, X, $<_X$, a and b are also arbitrary, so that the proposed universal sentence follows now to be true. □

Exercise 3.62. Prove for any linearly ordered set $(X, <_X)$ that the left-closed and right-open interval from an a in X to a b in X can be written as the difference of the left-closed, right-unbounded interval beginning in a and the left-closed, right-unbounded interval beginning in b, i.e.

$$\forall a, b\,(\,a, b \in X \;\Rightarrow\; [a, b) = [a, +\infty) \setminus [b, +\infty)\,). \tag{3.468}$$

Exercise 3.63. Verify for any linearly ordered set $(X, <_X)$ that the left-open and right-closed interval from an element a of X to an element b of X can be written as

a) the difference of the open, right-unbounded interval beginning in a and the open, right-unbounded interval beginning in a, i.e.

$$\forall a, b\,(\,a, b \in X \;\Rightarrow\; (a, b] = (a, +\infty) \setminus (b, +\infty)\,). \tag{3.469}$$

b) the difference of the left-unbounded, right-closed interval ending in b and the left-unbounded, right-closed interval ending in a, i.e.

$$\forall a, b\,(\,a, b \in X \;\Rightarrow\; (a, b] = (-\infty, b] \setminus (-\infty, a]\,). \tag{3.470}$$

(Hint: Proceed as in the proof of Proposition 3.136.)

Proposition 3.137. *For any linearly ordered set $(X, <_X)$ such that X is not bounded from above and for any element $a \in X$, it is true that the left-closed and right-unbounded interval $[a, +\infty)$ is not bounded from above.*

Proof. Letting X, $<_X$ and a be arbitrary such that $(X, <_X)$ is a linearly ordered without an upper bound and such that a is an element of X, we establish the negation

$$\neg \exists u \, (u \in X \ \wedge \ \forall x \, (x \in [a, +\infty) \Rightarrow x \leq_X u)).$$

First, we apply the Negation Law for existential conjunctions and write the preceding the negation as the equivalent universal sentence

$$\forall u \, (u \in X \Rightarrow \neg \forall x \, (x \in [a, +\infty) \Rightarrow x \leq_X u)). \tag{3.471}$$

We now take an arbitrary $\bar{u}$, and we prove the implication by contradiction, assuming $\bar{u} \in X$ and the negation of the negated universal sentence to be true. The latter assumption yields then with the Double Negation Law the true universal sentence

$$\forall x \, (x \in [a, +\infty) \Rightarrow x \leq_X \bar{u}). \tag{3.472}$$

Let us observe here the truth of $a \leq_X a$ in light of the reflexivity of the induced reflexive partial ordering $\leq_X$. This inequality gives us $a \in [a, +\infty)$ by definition of a left-closed and right-unbounded interval in X, and this yields $a \leq_X \bar{u}$ with the preceding universal sentence. Because we assumed that an upper bound for X does not exist, we also have the true negation

$$\neg \exists u \, (u \in X \ \wedge \ \forall x \, (x \in X \Rightarrow x \leq_X u)),$$

which we can evidently write in the equivalent form

$$\forall u \, (u \in X \Rightarrow \neg \forall x \, (x \in X \Rightarrow x \leq_X u)).$$

Therefore, the assumed $\bar{u} \in X$ implies $\neg \forall x \, (x \in X \Rightarrow x \leq_X \bar{u})$, which in turn implies (according to the Negation Law for universal implications) that there exists a constant, say $\bar{x}$, satisfying $\bar{x} \in X$ and $\neg \bar{x} \leq_X \bar{u}$. The latter gives us $\bar{u} <_X \bar{x}$ with the Negation Formula for $\leq$, and this implies in conjunction with the previously obtained $a \leq_X \bar{u}$ the inequality $a <_X \bar{x}$ by means of the Transitivity Formula for $\leq$ and $<$. Then, the disjunction $a <_X \bar{x} \vee a = \bar{x}$ also holds, so that $a \leq_X \bar{x}$ follows to be true by definition of an induced reflexive partial ordering. Consequently, we find $\bar{x} \in [a, +\infty)$ with the definition of a left-closed and right-unbounded interval, which further implies $\bar{x} \leq_X \bar{u}$ with (3.472), and subsequently also $\neg \bar{u} <_X \bar{x}$ with the Negation Formula for $<$. As $\bar{u} <_X \bar{x}$ also holds, we arrived at a contradiction, which completes the proof of the implication in (3.471). Since $\bar{u}$ is arbitrary, we therefore conclude that the universal sentence (3.471) is true, which proves the equivalent assertion that an upper bound for $[a, +\infty)$ does not exist. Because X, $<_X$ and a were initially arbitrary, we now further conclude that the proposed universal sentence holds. □

Exercise 3.64. Show for any linearly ordered set $(X, <_X)$ such that X is not bounded from below and for any element $b \in X$ that the left-unbounded and right-closed interval $(-\infty, b]$ is not bounded from below.

Proposition 3.138. *For any linearly ordered set $(X, <_X)$ such that the maximum of X does not exist and for any element $a \in X$, it is true that*

a) there exists an element in the open, right-unbounded interval beginning in a which is greater than a, i.e.

$$\exists x\, (x \in (a, +\infty) \wedge x >_X a). \tag{3.473}$$

b) the open, right-unbounded interval beginning in a is nonempty, i.e.

$$(a, +\infty) \neq \emptyset. \tag{3.474}$$

Proof. We take arbitrary sets X and $<_X$, for which we assume that $<_X$ is a linear ordering of X (inducing the total ordering $\leq_X$ of X) and that the maximum of X does not exist. The latter assumption can be stated as the negation $\neg \exists m\, (m \in X \wedge m = \max X)$, noting that X is a subset of itself according to (2.10). This negation implies with the Negation Law for existential conjunctions $\forall m\, (m \in X \Rightarrow \neg m = \max X)$. We now take an arbitrary set a, and we assume a to be an element of X, so that the preceding universal sentence yields the true negation $\neg a = \max X$. According to the definition of a maximum, this implies

$$\neg[\forall x\, (x \in X \Rightarrow x \leq_X a) \wedge a \in X],$$

so that the disjunction

$$\exists x\, (x \in X \wedge \neg x \leq_X a) \vee a \notin X,$$

follows to be true with De Morgan's Law for the conjunction and the Negation Law for universal implications. Since we assumed $a \in X$ to be true, the second part of the preceding disjunction is false, so that its first part must be true. This means that there exists a particular element $\bar{x} \in X$ with

$\neg\bar{x} \leq_X a$. The latter implies then with the Negation Formula for $\leq$ the truth of $\bar{x} >_X a$, which in turn gives $\bar{x} \in (a, +\infty)$ by definition of an open and right-unbounded interval in X. We thus proved the existential sentence (3.473), and as $\bar{x} \in (a, +\infty)$ clearly shows that the interval $(a, +\infty)$ is nonempty, we established the truth also of (3.429). Because the sets X, $<_X$ and a were arbitrary, we can now infer from the truth of a) and b) the truth of the proposition. □

Exercise 3.65. Show for any linearly ordered set $(X, <_X)$ such that the minimum of X does not exist and for any element $b \in X$ that

a) there exists an element in the open, left-unbounded interval ending in b which is less than b, i.e.

$$\exists x\,(x \in (-\infty, b) \,\wedge\, x <_X b). \tag{3.475}$$

b) the open and left-unbounded interval ending in b is nonempty, i.e.

$$(-\infty, b) \neq \emptyset. \tag{3.476}$$

Proposition 3.139. *For any partially ordered set $(X, \leq_X)$ such that the maximum of X exists and for any element $a \in X$, it is true that*

a) the open and right-unbounded interval beginning in a is identical with the left-open and right-closed interval from a to $\max X$, i.e.

$$(a, +\infty) = (a, \max X]. \tag{3.477}$$

b) the left-closed and right-unbounded interval beginning in a is identical with the closed interval from a to $\max X$, i.e.

$$[a, +\infty) = [a, \max X]. \tag{3.478}$$

Proof. Letting X, $\leq_X$ and a be arbitrary such that $(X, \leq_X)$ is partially ordered, such that the maximum of X exists and such that $a \in X$ holds, we may prove a) via the Equality Criterion for sets. For this purpose, we verify the universal sentence

$$\forall x\,(x \in (a, +\infty) \Leftrightarrow x \in (a, \max X]), \tag{3.479}$$

letting x be arbitrary. On the one hand, the assumption $x \in (a, +\infty)$ implies $x \in X$ and $a <_X x$ with (3.417). Since the maximum of X is by definition an upper bound for X (contained in X), we have that $x \in X$ implies $x \leq_X \max X$, so that the inequalities $a <_X x \leq_X \max X$ hold.

According to the definition of a left-open and right-closed interval, this finding in turn implies $x \in (a, \max X]$, which is the desired consequent of the first part ('$\Rightarrow$') of the equivalence in (3.479). On the other hand, the converse assumption $x \in (a, \max X]$ implies (by definition of a left-open and right-closed interval) the truth of the inequalities $a <_X x \leq_X \max X$, so that $a <_X x$ is especially true. Consequently, we obtain $x \in (a, +\infty)$ by definition of an open and right-unbounded interval, proving the second part ('$\Leftarrow$') of the equivalence. Since x is arbitrary, we may therefore conclude that (3.479) holds, and this universal sentence implies now the truth of (3.477), and thus the truth of a). Then, Part b) can be proved in analogy to Part a). As X, $\leq_X$ and a were initially arbitrary, we may infer from the truth of a) and b) the truth of the proposed universal sentence. □

Exercise 3.66. Prove Part b) of Proposition 3.139 in analogy to Part a). Show then for any partially ordered set $(X, \leq_X)$ such that the minimum of X exists and for any element $b \in X$ that

c) the open and left-unbounded interval ending in b is identical with the left-closed and right-open interval from $\min X$ to b, i.e.

$$(-\infty, b) = [\min X, b). \tag{3.480}$$

d) the left-unbounded and right-closed interval ending in b is identical with the closed interval from $\min X$ to b, i.e.

$$(-\infty, b] = [\min X, b]. \tag{3.481}$$

Note 3.15. As a consequence of the preceding Proposition 3.139 and Exercise 3.66, we may rewrite the previously established sentences concerning left- or right-unbounded intervals in 'closed forms' by using the minimum or the maximum of the underlying set X if they exist.

The next results follow immediately from Proposition 3.128, Corollary 3.129 and Exercise 3.57.

Corollary 3.140. *The following sentences are true for any linearly ordered set* $(X, <_X)$ *for which* $\min X$ *and* $\max X$ *both exist.*

$$\forall b \, (b \in X \Rightarrow [\min X, b) = [b, \max X]^c), \tag{3.482}$$

$$\forall a \, (a \in X \Rightarrow [a, \max X] = [\min X, a)^c), \tag{3.483}$$

$$\forall b \, (b \in X \Rightarrow [\min X, b] = (b, \max X]^c), \tag{3.484}$$

$$\forall a \, (a \in X \Rightarrow (a, \max X] = [\min X, a]^c). \tag{3.485}$$

The next result is obtained from Proposition 3.135

Corollary 3.141. *For any set X and any linear ordering $<_X$ such that the minimum and the maximum of X exist both, and for any elements $a, b \in X$, it is true that the complement of the closed interval from a to b (with respect to X) can be written as the union of the left-closed, right-open interval from the minimum of X to a and the left-open, right-closed interval from b to the maximum of X, i.e.*

$$[a, b]^c = [\min X, a) \cup (b, \max X]. \tag{3.486}$$

We now similarly specialize the findings of Proposition 3.136, Exercise 3.62 and Exercise 3.63.

Corollary 3.142. *The following sentences are true for any linearly ordered set $(X, <_X)$ for which $\min X$ and $\max X$ both exist.*

$$\forall a, b\, (a, b \in X \;\Rightarrow\; [a, b) = [\min X, b) \setminus [\min X, a)), \tag{3.487}$$
$$\forall a, b\, (a, b \in X \;\Rightarrow\; [a, b) = [a, \max X] \setminus [b, \max X]), \tag{3.488}$$
$$\forall a, b\, (a, b \in X \;\Rightarrow\; (a, b] = (a, \max X] \setminus (b, \max X]), \tag{3.489}$$
$$\forall a, b\, (a, b \in X \;\Rightarrow\; (a, b] = [\min X, b] \setminus [\min X, a]). \tag{3.490}$$

In what follows we intend to elaborate some common aspects of intervals, for which task it will be useful to subsume the previously introduced interval types.

Definition 3.35 (Interval). We say for any partially ordered set $(X, <_X)$ that a set I is an *interval in X* iff

$$\begin{aligned} & I \in \{[a, b] : a, b \in X\} \;\vee\; I \in \{(a, b) : a, b \in X\} \\ \vee\, & I \in \{(a, b] : a, b \in X\} \;\vee\; I \in \{[a, b) : a, b \in X\} \\ \vee\, & I \in \{(a, +\infty) : a \in X\} \vee I \in \{[a, +\infty) : a \in X\} \\ \vee\, & I \in \{(-\infty, b) : b \in X\} \vee I \in \{(-\infty, b] : b \in X\} \\ \vee\, & I = \emptyset \\ \vee\, & I = X. \end{aligned}$$

We now use open intervals to define a new type of subset of a partially ordered set.

Definition 3.36 (Convex set (with respect to a partial ordering)). For any partially ordered set $(X, <_X)$, we say that a set A is *convex* in X with respect to $<_X$ iff

1. A is a subset of X, i.e.
$$A \subseteq X, \tag{3.491}$$
and

2. the open interval in X from any element a in A to any element b in A is included in A, i.e.

$$\forall a, b\,(a, b \in A \Rightarrow (a, b)_X \subseteq A). \tag{3.492}$$

Exercise 3.67. Show for any partially ordered set $(X, <_X)$ that a subset A of X is convex in X with respect to $<_X$ iff

$$\forall a, b\,(a, b \in A \Rightarrow \forall x\,(a <_X x <_X b \Rightarrow x \in A)). \tag{3.493}$$

Proposition 3.143. *It is true for any partially ordered set $(X, <_X)$ and any elements $x, y \in X$ that the intervals*

$$[x, y],\ (x, y),\ (x, y],\ [x, y),\ (x, +\infty),\ [x, +\infty),\ (-\infty, y),\ (-\infty, y],\ \emptyset,\ X$$

are all convex in X with respect to $<_X$.

Proof. We let in the following X, $<_X$, x and y be arbitrary such that $(X, <_X)$ is a partially ordered set and such that x and y are elements of X. Then, $\leq_X$ denotes the induced reflexive partial ordering of X.

Regarding the interval $[x, y]$ in X, we observe first that the inclusion $[x, y] \subseteq X$ is true according to (3.352), so that the set $[x, y]$ satisfies Property 1 of a convex set in X with respect to $<_X$. To establish Property 2, we verify

$$\forall a, b\,(a, b \in [x, y] \Rightarrow (a, b) \subseteq [x, y]), \tag{3.494}$$

taking arbitrary constants a and b, assuming $a, b \in [x, y]$ to be true, and showing that the inclusion $(a, b) \subseteq [x, y]$ also holds. For this purpose, we apply the definition of a subset and prove the equivalent universal sentence

$$\forall z\,(z \in (a, b) \Rightarrow z \in [x, y]), \tag{3.495}$$

letting z be arbitrary and assuming $z \in (a, b)$ to be true. This assumption gives us now, by definition of an open interval in X, the inequalities $a <_X z$ and $z <_X b$. Furthermore, the previously made assumption $a, b \in [x, y]$ yields, by definition of a closed interval in X, the inequalities $x \leq_X a \leq_X y$ and $x \leq_X b \leq_X y$. Combining now $x \leq_X a$ with $a <_X z$, we obtain $x <_X z$ with the Transitivity Formula for $\leq$ and $<$; similarly, $z <_X b$ in connection with $b \leq_X y$ yields $z <_X y$ with the Transitivity Formula for $<$ and $\leq$. Then, the disjunctions $x <_X z \vee x = z$ and $z <_X y \vee z = y$ also hold, so that the definition of an induced reflexive partial ordering gives $x \leq_X z$ and $z \leq_X y$. Consequently, the definition of a closed interval in X yields the desired consequent $z \in [x, y]$ of the implication in (3.495). Here, z was arbitrary, so that the universal sentence (3.495) follows to be true, which in turn implies the desired inclusion $(a, b) \subseteq [x, y]$. Thus, the proof of the implication in (3.494) is also complete. Since a and b are arbitrary, we may now infer from the truth of that implication the truth of the universal sentence (3.494). This means that the interval $[x, y]$ in X satisfies also Property 2 of a convex set in X with respect to $<_X$, which then holds universally because x and y are arbitrary.

The proofs for the remaining intervals are carried out similarly.

As X and $<_X$ were arbitrary, the proposition follows then to be true. □

Exercise 3.68. Complete the proof of Proposition 3.143.

(Hint: Use the transitivity of $<_X$.)

Proposition 3.144. *The following implications are true for any linearly ordered set* $(X, <_X)$*, any convex set* A *in* X *w.r.t.* $<_X$ *and any* $a \in X$*.*

$$a \in A \;\Rightarrow\; A \cap (a, +\infty)_X = (a, +\infty)_A, \tag{3.496}$$

$$a \notin A \;\Rightarrow\; [A \cap (a, +\infty)_X = A \,\vee\, A \cap (a, +\infty)_X = \emptyset]. \tag{3.497}$$

Proof. We take arbitrary X, $<_X$, A and $\bar{a}$, assuming $(X, <_X)$ to be a linearly ordered set, assuming A to be a convex set in X with respect to $<_X$, and assuming $\bar{a}$ to be an element of X. Thus, the open and right-unbounded interval $(\bar{a}, +\infty)_X$ is defined, and the convex set A satisfies by definition $A \subseteq X$ as well as (3.492).

To prove the first implication (3.496) directly, we assume $\bar{a} \in A$ to be true, and we establish the consequent by means of the Equality Criterion for sets, i.e. by verifying the equivalent universal sentence

$$\forall y \, (y \in A \cap (\bar{a}, +\infty)_X \Leftrightarrow y \in (\bar{a}, +\infty)_A). \tag{3.498}$$

For this purpose, we let y be arbitrary and assume first $y \in A \cap (\bar{a}, +\infty)_X$ to hold, so that $y \in A$ and $y \in (\bar{a}, +\infty)_X$ follow to be true by definition of the intersection of two sets. The latter implies $\bar{a} <_X y$ with the definition of an open and right-unbounded interval in X. Because of $\bar{a}, y \in A$, the preceding inequality further implies $\bar{a} <_A y$ according to the Irreflexive partial ordering of subsets, so that $y \in (\bar{a}, +\infty)_A$ follows to be true by definition of an open and right-open interval in A. Thus, the first part ('$\Rightarrow$') of the equivalence in (3.498) holds.

Regarding the second part ('$\Leftarrow$'), we now assume $y \in (\bar{a}, +\infty)_A$ to be true, which yields $y \in A$ as well as $\bar{a} <_A y$, according to (3.417). Due to $\bar{a}, y \in A$, that inequality in turn implies $\bar{a} <_X y$ (with the Irreflexive partial ordering of subsets), and then evidently $y \in (\bar{a}, +\infty)_X$, which is the desired consequent of the second part of the equivalence to be proven. Therefore, that implication is true, and as y was arbitrary, we may now infer from that equivalence the truth of the universal sentence (3.498), and then also the truth of the equation $A \cap (\bar{a}, +\infty)_X = (\bar{a}, +\infty)_A$. This finding in turn proves the implication (3.496).

We prove the second implication (3.497) also directly, assuming $\bar{a} \notin A$ to be true. Let us first verify the assertion that $\bar{a}$ is a lower or an upper bound for A with respect to the induced total ordering $\leq_X$, i.e. that the disjunction

$$\forall y\,(y \in A \Rightarrow \bar{a} \leq_X y) \,\vee\, \forall y\,(y \in A \Rightarrow y \leq_X \bar{a}) \tag{3.499}$$

holds. To do this, we apply a proof by contradiction, assuming the negation of that disjunction to be true, so that De Morgan's Law for the disjunction gives us the true sentence

$$\neg\forall y\,(y \in A \Rightarrow \bar{a} \leq_X y) \,\wedge\, \neg\forall y\,(y \in A \Rightarrow y \leq_X \bar{a}).$$

We therefore obtain with the Negation Law for universal implications

$$\exists y\,(y \in A \,\wedge\, \neg\bar{a} \leq_X y) \,\wedge\, \exists y\,(y \in A \,\wedge\, \neg y \leq_X \bar{a}).$$

Thus, there are particular constants $y_1, y_2 \in A$ with $\neg\bar{a} \leq_X y_1$ as well as $\neg y_2 \leq_X \bar{a}$. These inequalities imply with the Negation Formula for $\leq$ the inequalities $y_1 <_X \bar{a}$ and $\bar{a} <_X y_2$, respectively, so that $\bar{a} \in (y_1, y_2)$ follows to be true by definition of an open interval in X. Recalling now the assumption that A is convex in X with respect to $<_X$, it follows from $y_1, y_2 \in A$ that the inclusion $(y_1, y_2) \subseteq A$ holds. With this, $\bar{a} \in (y_1, y_2)$ implies $\bar{a} \in A$ by definition of a subset, which finding contradicts the initial assumption $\bar{a} \notin A$, so that the proof of the disjunction (3.499) is now complete. In the next step, we use this true disjunction to prove the desired disjunction in (3.497) by cases.

In the first case that $\bar{a}$ is a lower bound for A with respect to $\leq_X$, we may establish the equation $A \cap (\bar{a}, +\infty)_X = A$ by means of the Equality Criterion for sets, i.e. by proving equivalently

$$\forall y\,(y \in A \cap (\bar{a}, +\infty)_X \Leftrightarrow y \in A). \tag{3.500}$$

Letting y be arbitrary and assuming first $y \in A \cap (\bar{a}, +\infty)_X$ to be true, the definition of the intersection of two sets gives us especially the desired consequent $y \in A$. Assuming conversely $y \in A$ to be true, we obtain $\bar{a} \leq_X y$ with the currently assumed first part of the disjunction (3.499); here, the truth of $y \in A$ and of $\bar{a} \notin A$ implies $y \neq \bar{a}$ with (2.4), and the conjunction of $\bar{a} \leq_X y$ and this inequality $\bar{a} \neq y$ implies then $\bar{a} <_X y$ with the definition of an induced reflexive partial ordering. We obtain then $y \in$

$(\bar{a}, +\infty)_X$ by definition of an open and right-unbounded interval in X. In conjunction with the assumed $y \in A$, this further implies $y \in A \cap (\bar{a}, +\infty)_X$ (by definition of the intersection of two sets), as desired. Because y is arbitrary, we may therefore conclude that (3.500) is true, which universal sentence implies then $A \cap (\bar{a}, +\infty)_X = A$; thus, the disjunction in (3.497) holds as well.

In the second case that $\bar{a}$ is an upper bound for A with respect to $\leq_X$, we may establish $A \cap (\bar{a}, +\infty)_X = \emptyset$ via the definition of the empty set, i.e. by demonstrating the truth of

$$\forall y \, (y \notin A \cap (\bar{a}, +\infty)_X). \tag{3.501}$$

We take an arbitrary y, and we prove $y \notin A \cap (\bar{a}, +\infty)_X$ by contradiction, assuming the negation of that sentence to be true. Then, $y \in A \cap (\bar{a}, +\infty)_X$ holds in view of the Double Negation Law, with the evident consequence that $y \in A$ and $y \in (\bar{a}, +\infty)_X$ are both true. Here, the latter finding gives us the inequality $\bar{a} <_X y$, which in turn implies the truth of $\neg y \leq_X \bar{a}$. However, since we currently assume the second part of the disjunction (3.499) to hold, it follows from $y \in A$ that $y \leq_X \bar{a}$ is also true, so that we arrived at a contradiction. Thus, the proof of $y \notin A \cap (\bar{a}, +\infty)_X$ is complete, and as y was arbitrary, we may infer from the preceding negation the truth of (3.501). This universal sentence gives us $A \cap (\bar{a}, +\infty)_X = \emptyset$ and then also the disjunction in (3.497), which thus holds in any case.

Having now completed the proofs of the implications (3.496) and (3.497), we may furthermore conclude that the proposed universal sentence is true, since X, $<_X$, A and $\bar{a}$ were initially arbitrary. □

Exercise 3.69. Prove the following implications for any linearly ordered set $(X, <_X)$, any convex set A in X with respect to $<_X$ and any $b \in X$.

$$b \in A \;\Rightarrow\; A \cap (-\infty, b)_X = (-\infty, b)_A, \tag{3.502}$$

$$b \notin A \;\Rightarrow\; [A \cap (-\infty, b)_X = A \,\vee\, A \cap (-\infty, b)_X = \emptyset]. \tag{3.503}$$

(Hint: Proceed in analogy to the proof of Proposition 3.144.)

3.4. Functions

Definition 3.37 (Function/mapping, function value, argument, codomain). We say that a set f is a *function* or a *mapping* iff

1. f is a binary relation and
2. ordered pairs in f with identical first coordinates also have identical second coordinates, that is,

$$\forall x, y, y' \left([(x, y) \in f \wedge (x, y') \in f] \Rightarrow y = y' \right). \tag{3.504}$$

For any $(x, y) \in f$, we call y the *function value* at (the *argument*) x.

Furthermore, we say for any sets X and Y that a function f is a function from X to Y, symbolically

$$f : X \to Y \tag{3.505}$$

if, and only if,

1. the domain of f is identical with X, that is,

$$\mathrm{dom}(f) = X, \tag{3.506}$$

   and
2. the range of f is a subset of Y, that is,

$$\mathrm{ran}(f) \subseteq Y. \tag{3.507}$$

Here, we call Y the *codomain* of f.

Notation 3.4. Instead of $(x, y) \in f$ we will usually write

$$y = f(x) \tag{3.508}$$

or

$$x \mapsto y. \tag{3.509}$$

We now bring out more clearly the fact a function value is uniquely determined by the argument.

Theorem 3.145 (Function Criterion). *For any sets X and Y and any binary relation $f \subseteq X \times Y$, it is true that f is a function with domain X and codomain Y iff, for any element x of X, there exists a unique element y of Y such that the ordered pair (x, y) is an element of f, i.e. it is true that*

$$f : X \to Y \Leftrightarrow \forall x \left(x \in X \Rightarrow \exists! y \left(y \in Y \wedge (x, y) \in f \right) \right). \tag{3.510}$$

Proof. We let X and Y be arbitrary sets and f an arbitrary binary relation.

To prove the first part ('$\Rightarrow$') of the equivalence, we assume that f is a function from X to Y, i.e. that $\mathrm{dom}(f) = X$ and $\mathrm{ran}(f) \subseteq Y$ hold and that f satisfies (3.504). Then, to demonstrate the truth of the right-hand side, we let x be arbitrary and show that this implies $\exists! y\,(y \in Y \,\wedge\, (x,y) \in f)$, or equivalently (using the Criterion for unique existence)

$$\begin{aligned}&\exists y\,(y \in Y \,\wedge\, (x,y) \in f)\\ &\quad \wedge\, \forall y, y'\,([y \in y \,\wedge\, (x,y) \in f \,\wedge\, y' \in Y \,\wedge\, (x,y') \in f] \Rightarrow y = y').\end{aligned} \quad (3.511)$$

Since X is the domain of f, it follows by definition that $x \in X$ implies that there exists an element, say $\bar{y}$, with $(x,\bar{y}) \in f$. Thus, $\bar{y}$ is an element of the range of f, and therefore $\bar{y} \in Y$ holds with the definitions of a codomain and of a subset. This proves the first part of the conjunction (3.511). To prove the second part, we let y and y' be arbitrary and assume $y \in Y$, $(x,y) \in f$, $y' \in Y$, and $(x,y') \in f$. As this multiple conjunction implies in particular $(x,y) \in f \wedge (x,y') \in f$, it follows with the assumed (3.504) that $y = y'$ is true. As y and y' are arbitrary, we therefore conclude that that the second part of the conjunction (3.511) holds, which proves this conjunction, and thus the uniquely existential sentence in (3.510). Since x was also arbitrary, we further conclude that the right-hand side of the equivalence (3.510) is true.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume the right-hand side. To prove $f : X \to Y$, we first verify $\mathrm{dom}(f) = X$, i.e.

$$\forall x\,(x \in X \Leftrightarrow x \in \mathrm{dom}(f)). \quad (3.512)$$

For this purpose, we let x be arbitrary and first assume $x \in X$. With the assumed right-hand side of (3.510), this implies that there exists the unique y with $y \in Y$ and $(x,y) \in f$. Therefore, x is an element of the domain of f. We now assume conversely $x \in \mathrm{dom}(f)$, so that there exists (by definition of a domain) an element, say $\bar{y}$, such that $(x,\bar{y}) \in f$. The latter implies with the initial assumption $f \subseteq X \times Y$ that $(x,\bar{y}) \in X \times Y$, so that $x \in X$ holds by definition of a Cartesian product. As x was arbitrary, we therefore conclude that (3.512) is true, which means $\mathrm{dom}(f) = X$. Next, we verify $\mathrm{ran}(f) \subseteq Y$, which means

$$\forall y\,(y \in \mathrm{ran}(f) \Rightarrow y \in Y)). \quad (3.513)$$

by definition of a subset. To do this, we let y be an arbitrary element of the range of f. Therefore, there exists an element, say $\bar{x}$, with $(\bar{x},y) \in f$, where $\bar{x}$ is then evidently an element of the domain X. Then, $\bar{x} \in X$ implies with the assumed right-hand side of (3.510) that there exists the unique element

y' in Y with $(\bar{x}, y') \in f$. Therefore, $(\bar{x}, y) = (\bar{x}, y')$, so that $y' = y$ follows with (3.3). Then, $y' \in Y$ implies $y \in Y$. As y is arbitrary, we therefore conclude that (3.513) holds as well.

We now show f satisfies also (3.504). We let x, y and y' be arbitrary and assume $(x, y) \in f \wedge (x, y') \in f$. Thus, x is an element of the domain X and y, y' are elements of the range of f, thus of Y. Then, $x \in X$ implies with the assumption that the uniquely existential sentence $\exists! y\,(y \in Y \ \wedge\ (x, y) \in f)$ or equivalently (3.511) holds. The latter conjunction implies in particular its second part, from which it then follows with the previously established $y, y' \in Y$ and with the assumption $(x, y), (x, y') \in f$ that $y = y'$ holds. Since x, y and y' are arbitrary, it follows that f satisfies (3.504). We thus showed that f is a function from X to Y, which completes the proof of the proposed equivalence. As X, Y and f were also arbitrary, it follows that the theorem holds, as claimed. $\square$

The following method summarizes the application of the Function Criterion.

Method 3.1 (Verification that a binary relation is a function). To verify that a given binary relation $f \subseteq X \times Y$ is a function from X to Y, we may show for any element x of X that there exists a unique element y in Y such that the ordered pair formed by x and y is in f.

Proposition 3.146. *Any function $f : X \to Y$ is included in the Cartesian product of X and Y, that is,*

$$\forall X, Y, f\,(f : X \to Y \ \Rightarrow\ f \subseteq X \times Y). \tag{3.514}$$

Proof. We let X, Y and f be arbitrary sets and assume that f is a function from X to Y. Thus, f is a binary relation with $\mathrm{dom}(f) = X$ and $\mathrm{ran}(f) \subseteq Y$. Since $X \subseteq X$ holds according to (2.10), the conjunction $X \subseteq X \wedge \mathrm{ran}(f) \subseteq Y$ is true, which further implies

$$X \times \mathrm{ran}(f) \subseteq X \times Y \tag{3.515}$$

with (3.40). Furthermore, we have $f \subseteq \mathrm{dom}(f) \times \mathrm{ran}(f)$ because of (3.111), and therefore

$$f \subseteq X \times \mathrm{ran}(f). \tag{3.516}$$

The conjunction of (3.516) and (3.515) now yields the desired inclusion $f \subseteq X \times Y$ with (2.13), and since X, Y and f were arbitrary, we may therefore conclude that the proposed universal sentence is true. $\square$

Corollary 3.147. *For any X, Y, f, x and y it is true that, if f is a function from X to Y and if y is the value of f at x, then x is in X and y is in Y, that is,*

$$\forall X, Y, f, x, y\,([f : X \to Y \,\wedge\, y = f(x)] \Rightarrow [x \in X \,\wedge\, y \in Y]). \tag{3.517}$$

Proof. Letting X, Y, f, x and y be arbitrary and assuming $f : X \to Y$ as well as $y = f(x)$ to be true, we observe that the former assumption implies $f \subseteq X \times Y$ with (3.514), and that the latter assumption may be written as as $(x, y) \in f$ in view of Notation 3.4, which in turn implies $(x, y) \in X \times Y$ with the preceding inclusion and the definition of a subset. It then follows by definition of the Cartesian product of two sets that the desired conjunction $x \in X \,\wedge\, y \in Y$ is true. As X, Y, f, x and y were arbitrary, we may therefore conclude that (3.517) holds. □

Exercise 3.70. Verify the following sentences.

a) Any function f with domain X is a function from X to the range of f, that is,

$$\forall X, f\,([f \text{ is a function} \wedge \operatorname{dom}(f) = X] \;\Rightarrow\; f : X \to \operatorname{ran}(f)). \tag{3.518}$$

(Hint: Apply (2.10).)

b) Any function f from a set X to a subset Y of a set Z is also a function from X to Z, that is,

$$\forall X, Y, f, Z\,([f : X \to Y \,\wedge\, Y \subseteq Z] \Rightarrow\; f : X \to Z). \tag{3.519}$$

(hint: Use (2.13).)

Definition 3.38 (Transformation). We say for any sets X, Y and any function $f : X \to Y$ that f is a *transformation* (on X) iff $X = Y$.

Note 3.16. The domain and codomain of a transformation f coincide, which we may therefore write as

$$f : X \to X. \tag{3.520}$$

Our next task is to construct a set which consists of all functions having a fixed, common domain and codomain.

Theorem 3.148. *The following sentences are true for any sets X and Y.*

a) There exists a unique set Y^X such that an element f is in Y^X iff f is in the power set of the Cartesian product of X and Y and moreover if f is a function from X to Y, that is,

$$\exists! Y^X\; \forall f\,(f \in Y^X \Leftrightarrow [f \in \mathcal{P}(X \times Y) \,\wedge\, f : X \to Y]).$$

b) The set Y^X satisfies also

$$\forall f\,(f \in Y^X \Leftrightarrow f : X \to Y). \tag{3.521}$$

Proof. We let X and Y be arbitrary sets. Concerning a), we use the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true existential sentence

$$\exists! Y^X\, \forall f\,(f \in Y^X \Leftrightarrow [f \in \mathcal{P}(X \times Y) \wedge \forall x, y, y'\,([(x,y) \in f \wedge (x,y') \in f] \\ \Rightarrow y = y') \wedge \mathrm{dom}(f) = X \wedge \mathrm{ran}(f) \subseteq Y]),$$

which clearly proves a). Thus, the set Y^X satisfies

$$\forall f\,(f \in Y^X \Leftrightarrow [f \in \mathcal{P}(X \times Y) \wedge f : X \to Y]). \tag{3.522}$$

Concerning b), we let f be arbitrary and assume first $f \in Y^X$, which implies in particular $f : X \Rightarrow Y$ in view of the preceding universal sentence. Conversely, we now assume $f : X \Rightarrow Y$ to be true, so that $f \subseteq X \times Y$ holds according to (3.514). This inclusion in turn implies $f \in \mathcal{P}(X \times Y)$ with the definition of a power set. Thus, the conjunction in (3.522) is true, which then implies $f \in Y^X$, completing the proof of the equivalence in (3.521). Since f is arbitrary, we may therefore conclude that the universal sentence (3.521) holds.

As X and Y were arbitrary, we may further conclude that the theorem is true. □

Definition 3.39 (Set of functions, set of transformations). For any sets X and Y we call the set (system)

$$Y^X \tag{3.523}$$

consisting of all functions from X to Y in the sense of

$$\forall f\,(f \in Y^X \Leftrightarrow f : X \to Y)$$

the *set of functions* from X to Y. In particular, we call

$$X^X \tag{3.524}$$

the *set of transformations* on X.

We conclude this introductory section on functions with a first basic, set-theoretical property.

Definition 3.40 (Bounded-from-above & bounded-from-below function, bounded & unbounded function). For any sets X and Y, any partial ordering $\leq$ of Y and any function $f : X \to Y$, we say that

(1) an element a in Y is a lower bound for f iff a is a lower bound for the range of f.

(2) f is *bounded from below* iff $\mathrm{ran}(f)$ is a bounded-from-below set.

(3) an element u in Y is an upper bound for f iff u is an upper bound for the range of f.

(4) f is *bounded from above* iff $\mathrm{ran}(f)$ is a bounded-from-above set.

(5) f is *bounded* iff $\mathrm{ran}(f)$ is a bounded set.

(6) f is *unbounded* iff f is not bounded.

3.4.1. Basic laws for functions

Proposition 3.149. *For any function f it is true that two distinct function values cannot have identical arguments, i.e.*

$$\forall x, x' \, (x, x' \in \mathrm{dom}(f) \Rightarrow [f(x) \neq f(x') \Rightarrow x \neq x']). \tag{3.525}$$

Proof. We let f be arbitrary and assume that f is a function. Next, we let $\bar{x}$ and $\bar{x}'$ be arbitrary and assume these to be elements of the domain of f. Observing that the function f is a binary relation, we now see that $\bar{x}, \bar{x}' \in \mathrm{dom}(f)$ implies by definition of a domain that there exist corresponding elements, say $\bar{y}$ and $\bar{y}'$, such that $(\bar{x}, \bar{y}), (\bar{x}', \bar{y}') \in f$ holds. In view of Notation 3.4, we thus have $\bar{y} = f(\bar{x})$ and $\bar{y}' = f(\bar{x}')$. We may now prove the implication $f(\bar{x}) \neq f(\bar{x}') \Rightarrow \bar{x} \neq \bar{x}'$ by contraposition, assuming $\neg \bar{x} \neq \bar{x}'$ to be true, so that $\bar{x} = \bar{x}'$ follows to be true with the Double Negation Law. Consequently, the previously established $(\bar{x}', \bar{y}') \in f$ gives $(\bar{x}, \bar{y}') \in f$ via substitution based on the preceding equation, so that the conjunction $(\bar{x}, \bar{y}) \in f \wedge (\bar{x}, \bar{y}') \in f$ is true. According to Property 2 of a function, this conjunction further implies $\bar{y} = \bar{y}'$, and therefore substitution yields $f(\bar{x}) = f(\bar{x}')$. This completes the proof by contraposition, so that the implications in (3.525) are true. Since $\bar{x}$ and $\bar{x}'$ are arbitrary, we may therefore conclude that the universal sentence (3.525) holds; as f was initially arbitrary, we may further conclude that the proposition is true. □

An application of the Law of Contraposition immediately yields an alternative representation of Property 2 of a function.

Corollary 3.150. *For any function f it is true that identical arguments imply identical corresponding functions, i.e.*

$$\forall x, x' \,(x, x' \in \mathrm{dom}(f) \Rightarrow [x = x' \Rightarrow f(x) = f(x')]). \tag{3.526}$$

Proposition 3.151. *There exists a unique function from $\emptyset$ to any set Y, that is,*

$$\forall Y \,\exists! f \,(f : \emptyset \to Y). \tag{3.527}$$

This function is the empty set $\emptyset$.

Proof. We let Y be an arbitrary set and prove the existential part first, recalling that $\emptyset$ is a binary relation due to Proposition 3.20; thus $\emptyset$ satisfies Property 1 of a function. We now demonstrate that $\emptyset$ satisfies also Property 2, that is, (3.504). For this purpose, we let x, y, y' be arbitrary and prove the implication

$$[(x, y) \in \emptyset \,\wedge\, (x, y') \in \emptyset] \Rightarrow y = y'.$$

Since $(x, y) \in \emptyset$ and $(x, y') \in \emptyset$ are both false by definition of the empty set, the conjunction and thus the antecedent is false. Therefore, the implication is true (no matter if $y = y'$ is true or false). As x, y and y' are arbitrary, we therefore conclude that (3.504) is true for $f = \emptyset$. This completes the proof that $\emptyset$ is a function. Let us also recall that $\mathrm{dom}(\emptyset) = \emptyset$ holds with (3.120) and that $\mathrm{ran}(\emptyset) = \emptyset$ holds with (3.121). Since $\emptyset \subseteq Y$ is true due to (2.43), we see that $\mathrm{ran}(\emptyset) \subseteq Y$ holds. We thus showed that $\emptyset$ is a function from $\emptyset$ to Y, which evidently proves the existential part.

To prove the uniqueness part, we let f and f' be arbitrary such that $f : \emptyset \to Y$ and $f' : \emptyset \to Y$ holds. Thus, f and f' are binary relations with $\mathrm{dom}(f) = \emptyset$ and $\mathrm{dom}(f') = \emptyset$. It then follows that $f = \emptyset$ and $f' = \emptyset$ because of (3.120), which equations then give the desired $f = f'$. This completes the proof of the uniquely existential sentence in (3.527), and since Y was arbitrary, we therefore conclude that the proposition is true. □

Proposition 3.152. *There is no function with nonempty domain and empty codomain, that is,*

$$\forall X \,(X \neq \emptyset \Rightarrow \neg\exists f \,(f : X \to \emptyset)). \tag{3.528}$$

Proof. We let X be an arbitrary set and prove the implication by contradiction. For this purpose, we assume $X \neq \emptyset$ and that there exists a function from X to $\emptyset$, say $\bar{f}$. Here, $X \neq \emptyset$ implies with (2.42) that there exists an element in X, say $\bar{x} \in X$. By Property 1 of a function, $\bar{f}$ is a binary relation (with domain X). Then, by definition of a domain, $\bar{x} \in X$ implies that there exists an element, say $\bar{y}$, such that $(\bar{x}, \bar{y}) \in \bar{f}$ holds. This implies by definition of a range that $\bar{y} \in \operatorname{ran}(\bar{f})$ is true, which shows that $\operatorname{ran}(\bar{f}) \neq \emptyset$. By definition of a codomain, $\operatorname{ran}(\bar{f}) \subseteq \emptyset$ is also true, which further implies $\operatorname{ran}(\bar{f}) = \emptyset$ with (2.46). The conjunction of this and the previously established $\operatorname{ran}(\bar{f}) \neq \emptyset$ constitutes a contradiction according to (1.11), so that the proof of the implication in (3.528) is complete. As X was arbitrary, we therefore conclude that the proposed universal sentence holds. □

Let us now apply the Function Criterion in a simple setting.

Proposition 3.153. *The Cartesian product of a set X and a singleton $\{y\}$ is a function from X to the singleton, that is,*

$$\forall X, y\,(X \times \{y\} \in \{y\}^X). \tag{3.529}$$

Proof. We let X and $\bar{y}$ be arbitrary and observe that $X \times \{\bar{y}\}$ is a binary relation (included in itself). We may therefore apply Method 3.1 to prove that this binary relation is a function from X to $\{\bar{y}\}$. To do this, we verify

$$\forall x\,(x \in X \Rightarrow \exists! y\,(y \in \{\bar{y}\} \,\wedge\, (x, y) \in X \times \{\bar{y}\})), \tag{3.530}$$

letting x be arbitrary and assuming $x \in X$ to be true. To establish the existential part, we observe the evident truth of $\bar{y} \in \{\bar{y}\}$, so that the conjunction $x \in X \,\wedge\, \bar{y} \in \{\bar{y}\}$ holds, which in turn implies $(x, \bar{y}) \in X \times \{\bar{y}\}$ with the definition of the Cartesian product of two sets. We thus showed that there exists an y with $y \in \{\bar{y}\}$ and $(x, y) \in X \times \{\bar{y}\}$. To establish the uniqueness part, we verify

$$\forall y, y'\,([y \in \{\bar{y}\} \wedge (\bar{x}, y) \in X \times \{\bar{y}\} \wedge y' \in \{\bar{y}\} \wedge (\bar{x}, y') \in X \times \{\bar{y}\}] \Rightarrow y = y'). \tag{3.531}$$

Letting y and y' be arbitrary and assuming $y, y' \in \{\bar{y}\}$ as well as

$$(\bar{x}, y), (\bar{x}, y') \in X \times \{\bar{y}\}$$

to be true, we now obtain from the former assumption with (2.169) the equations $y = \bar{y} = y'$, which give the desired consequent $y = y'$ of the implication in (3.531). Since y and y' are arbitrary, we may therefore conclude that the universal sentence (3.531) holds, so that the proof of the uniquely existential sentence in (3.530) is complete. Because $\bar{x}$ is also arbitrary, we may further conclude that the universal sentence (3.530) holds. It then follows from this with the Function Criterion that $X \times \{\bar{y}\} : X \to \{y\}$. Consequently, $X \times \{\bar{y}\}$ is an element of the set of functions $\{\bar{y}\}^X$. As X and $\bar{y}$ were initially arbitrary, we may now finally conclude that the proposed universal sentence (3.529) is true. □

Note 3.17. Every element of the domain X of a function $X \times \{y\}$ is associated with the unique element $y \in \{y\}$, which fact motivates the following definition.

Definition 3.41 (Constant function). For any X and any c we call the function $X \times \{c\}$, which we also symbolize by

$$g_c : X \to \{c\}, \tag{3.532}$$

the *constant function* on X with value c.

Notation 3.5. In case that Y is a codomain of a constant function $g_c : X \to \{c\}$, we also write

$$g_c : X \to Y. \tag{3.533}$$

Corollary 3.154. *The function values of a constant function $g_c : X \to \{c\}$ are identical with c for any element of the domain, i.e.*

$$\forall x\, (x \in X \Rightarrow g_c(x) = c). \tag{3.534}$$

Proof. Letting X, c and g_c be arbitrary sets, assuming $g_c : X \to \{c\}$ to be true, letting x also be arbitrary, and assuming moreover $x \in X$ to hold, it follows with the Function Criterion that there exists a unique element $y \in \{c\}$ with $(x, y) \in g_c$, i.e. with $y = g_c(x)$. As $y \in \{c\}$ implies $y = c$ with (2.169), we obtain the desired consequent $g_c(x) = c$ via substitution. Since x is arbitrary, we may therefore conclude that the universal sentence (3.534) is true. Because X, c and g_c were initially also arbitrary, the proposed sentence follows then to be true. □

Proposition 3.155. *The set of functions from a set X to a nonempty set Y is nonempty, that is,*

$$\forall X, Y\, (Y \neq \emptyset \Rightarrow Y^X \neq \emptyset). \tag{3.535}$$

Proof. We take arbitrary sets X and Y and prove the implication by cases, assuming first $Y \neq \emptyset$ and $X = \emptyset$ to be true. Then, we see in light of (3.527) that $\emptyset$ is a function from $X = \emptyset$ to Y, so that $\emptyset \in Y^X$ holds. Thus, there exists an element in Y^X, and therefore $Y^X \neq \emptyset$ follows to be true with (2.42). In the second case, we assume $Y \neq \emptyset$ and $X \neq \emptyset$ to be true. The former assumption implies with (2.42) that there exists an element in Y, say $\bar{y}$. With this element, we may form first the singleton $\{\bar{y}\}$ and then the Cartesian product $X \times \{\bar{y}\}$, which is by definition the constant function $g_{\bar{y}} : X \to \{\bar{y}\}$. Let us now observe that $\mathrm{ran}(g_{\bar{y}}) \subseteq \{\bar{y}\}$ holds by definition of a codomain, and moreover that $\bar{y} \in Y$ implies $\{\bar{y}\} \subseteq Y$ with (2.184). Consequently, we obtain from these two inclusions $\mathrm{ran}(g_{\bar{y}}) \subseteq Y$

with the transitivity of $\subseteq$, so that Y is also a codomain of $g_{\bar{y}}$. Thus, we have $g_{\bar{y}} : X \to Y$ and therefore $g_{\bar{y}} \in Y^X$, which clearly shows that $Y^X \neq \emptyset$ holds also in the second case. As X and Y were initially arbitrary sets, we may now infer from these findings the truth of the proposed universal sentence (3.535). □

The fact that the Cartesian product of two singletons constitutes a singleton formed by the ordered pair whose coordinates are the elements of the singletons (see Exercise 3.5) yields the following special case of a constant function.

Corollary 3.156. *The singleton formed by a pair (x, y) is a function from the singleton formed by x to the singleton formed by y, that is,*

$$\forall x, y\, (\{(x, y)\} \in \{y\}^{\{x\}}). \tag{3.536}$$

We now apply the Function Criterion to establish the following standard function.

Theorem 3.157. *The following sentences are true for any Y and any subset X of Y.*

a) There exists a unique set (system) j such that an element Z is in j iff Z is in $X \times Y$ and moreover if there is an element x such that Z is the ordered pair formed by x and x, that is,

$$\exists! j\, \forall Z\, (Z \in j \Leftrightarrow [Z \in X \times Y \,\wedge\, \exists x\, (Z = (x, x))]). \tag{3.537}$$

b) The set j is a function from X to Y, and this function satisfies

$$\forall x\, (x \in X \Rightarrow j(x) = x). \tag{3.538}$$

Proof. We let X and Y be arbitrary sets and assume that X is a subset of Y. Then, we may evidently apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true uniquely existential sentence (3.537), which proves a). Thus, the set j satisfies

$$\forall Z\, (Z \in j \Leftrightarrow [Z \in X \times Y \,\wedge\, \exists x\, (Z = (x, x))]). \tag{3.539}$$

Concerning b), let us first observe that $Z \in j$ implies in particular $Z \in X \times Y$ for any Z, so that $j \subseteq X \times Y$ follows to be true by definition of a subset. We may now apply Method 3.1 to verify that this binary relation j is a function from X to Y. For this purpose, we prove

$$\forall x\, (x \in X \Rightarrow \exists! y\, (y \in Y \,\wedge\, (x, y) \in j)), \tag{3.540}$$

letting $\bar{x}$ be arbitrary and assuming $\bar{x} \in X$ to be true. To establish the uniquely existential sentence in (3.540), we first prove the existential part. To do this, we observe that $\bar{x} \in X$ implies $\bar{x} \in Y$ with the initial assumption $X \subseteq Y$ and the definition of a subset. Thus, the conjunction $\bar{x} \in X \wedge \bar{x} \in Y$ holds, so that $(\bar{x}, \bar{x}) \in X \times Y$ follows to be true by definition of the Cartesian product of two sets. This finding shows that there exists an x such that $(\bar{x}, \bar{x}) = (x, x)$ holds. Together with $(\bar{x}, \bar{x}) \in X \times Y$, this existential sentence implies with (3.539) $(\bar{x}, \bar{x}) \in j$; together with the previously established $\bar{x} \in Y$, this shows that there exists an y such that $y \in Y$ and $(\bar{x}, y) \in j$ are true, proving the existential part of the uniquely existential sentence in (3.540).

Regarding the uniqueness part, we verify

$$\forall y, y' \left([y \in Y \;\wedge\; (\bar{x}, y) \in j \;\wedge\; y' \in Y \;\wedge\; (\bar{x}, y') \in j] \Rightarrow y = y' \right). \tag{3.541}$$

We let $\bar{y}$ and $\bar{y}'$ be arbitrary and assume $\bar{y}, \bar{y}' \in Y$ and $(\bar{x}, \bar{y}), (\bar{x}, \bar{y}') \in j$ to hold. On the one hand, $(\bar{x}, \bar{y}) \in j$ implies with (3.539) in particular that there exists an element, say $\bar{\bar{x}}$, such that $(\bar{x}, \bar{y}) = (\bar{\bar{x}}, \bar{\bar{x}})$ holds. This equation yields with the Equality Criterion for ordered pairs $\bar{x} = \bar{\bar{x}}$ and $\bar{y} = \bar{\bar{x}}$, which equations in turn imply (via substitution)

$$\bar{x} = \bar{y}. \tag{3.542}$$

On the other hand, $(\bar{x}, \bar{y}') \in j$ implies with (3.539) in particular that there is an element, say $\bar{\bar{x}}'$, with $(\bar{x}, \bar{y}') = (\bar{\bar{x}}', \bar{\bar{x}}')$. Therefore, the Equality Criterion for ordered pairs gives now $\bar{x} = \bar{\bar{x}}'$ as well as $\bar{y}' = \bar{\bar{x}}'$. Combining these two equations, we now obtain

$$\bar{x} = \bar{y}'.$$

Applying now substitution to this equation based on (3.542), we arrive at the desired $\bar{y} = \bar{y}'$, so that the proof of the implication in (3.541) is complete. As $\bar{y}$ and $\bar{y}'$ were arbitrary, we may therefore conclude that the uniqueness part (3.541) of the uniquely existential sentence in (3.540) holds as well. This in turn proves the implication in (3.540), and since $\bar{x}$ was arbitrary, we may now further conclude that the universal sentence (3.540) is true. This implies then $j : X \to Y$ with the Function Criterion (3.510).

It now remains for us to verify (3.538). Letting $\bar{x} \in X$ be arbitrary, we already showed earlier that this implies $(\bar{x}, \bar{x}) \in j$, which we may now write as $\bar{x} = j(\bar{x})$ by applying Notation 3.4. Thus, the implication in (3.538) is clearly true, and since $\bar{x}$ is arbitrary, we may finally conclude that j satisfies indeed (3.538). As X and Y were arbitrary in the proofs of a) and b), the theorem follows to be true. □

Definition 3.42 (Inclusion function/inclusion map). For any set Y and any $X \subseteq Y$ we call the function $j : X \to Y$ which maps every element of its domain into itself in the sense of

$$\forall x\,(x \in X \Rightarrow j(x) = x).$$

the *inclusion function* or the *inclusion map* from X to Y.

As there exists a vast variety of functions it is crucial to have a method at one's disposal to check whether two given functions are actually identical.

Theorem 3.158 (Equality Criterion for functions). *Two functions f and g with common domain X are equal iff their function values at any common element of their domain are identical, that is,*

$$\begin{aligned}&\forall X, f, g\,(f, g \text{ are functions with domain } X\\ &\quad \Rightarrow [f = g \Leftrightarrow \forall x\,(x \in X \Rightarrow f(x) = g(x))]).\end{aligned} \tag{3.543}$$

Proof. We let X, f and g be arbitrary sets and assume that f and g are functions with domain X. We first observe that the equivalence

$$f = g \;\Leftrightarrow\; \forall z\,(z \in f \Leftrightarrow z \in g) \tag{3.544}$$

holds because of the Equality Criterion for sets. Now, to prove the first part ('$\Rightarrow$') of the equivalence in (3.543), we assume $f = g$, or equivalently the right-hand side

$$\forall z\,(z \in f \Leftrightarrow z \in g) \tag{3.545}$$

of the equivalence (3.544), and then let $x \in X$ be arbitrary. As f is a function with domain X, there exists a unique function value $y = f(x)$, which means $(x, y) \in f$. Defining $z = (x, y)$, it follows with the assumption (3.545) that $z \in g$, that is, $(x, y) \in g$, which means $y = g(x)$ since g is a function on X; consequently, $y = f(x) = g(x)$. As x is arbitrary, the right-hand side of the equivalence in (3.543) is true.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume

$$\forall x\,(x \in X \Rightarrow f(x) = g(x)) \tag{3.546}$$

and then let z be arbitrary. To prove the first part ('$\Rightarrow$') of the equivalence $z \in f \Leftrightarrow z \in g$, we first assume $z \in f$, which means that there exists an element of the domain X of f, say $\bar{x}$, and an element of the range of f, say $\bar{y}$, such that $z = (\bar{x}, \bar{y})$ and $\bar{y} = f(\bar{x})$. Due to the assumption (3.546), $\bar{x} \in X$ implies $(\bar{y} =)\ f(\bar{x}) = g(\bar{x})$, that is, $\bar{y} = g(\bar{x})$, which means $(z =)\ (\bar{x}, \bar{y}) \in g$, that is, $z \in g$. We thus showed that $z \in f$ implies $z \in g$. To prove the second part ('$\Leftarrow$') of the equivalence $z \in f \Leftrightarrow z \in g$, we now assume $z \in g$, so that $z = (\bar{x}, \bar{y})$ and $\bar{y} = g(\bar{x})$ hold for particular $\bar{x} \in X$ and $\bar{y}$. Because of the assumption (3.546), $\bar{x} \in X$ implies $(\bar{y} =)\ g(\bar{x}) = f(\bar{x})$, i.e. $\bar{y} = f(\bar{x})$, which means $(z =)\ (\bar{x}, \bar{y}) \in f$, i.e. $z \in f$. We thus verified that $z \in g$ implies $z \in f$, which completes the proof of the equivalence $z \in f \Leftrightarrow z \in g$. Since z is arbitrary, we therefore conclude that the right-hand side of the equivalence (3.544) holds, and therefore $f = g$, i.e. the left-hand side of the equivalence in (3.543).

As X, f and g are arbitrary we then conclude that the universal sentence (3.543) is true. □

Method 3.2 (Verification that two given functions are equal). To verify that two given functions f and g with the same domain X are identical, we may show that $f(x) = g(x)$ holds for every element x of the domain X of f and g.

We demonstrate the preceding method for a simple situation.

Proposition 3.159. *For any x and any function f whose domain consists of x, it is true that $f = \{(x, f(x))\}$.*

Proof. We take arbitrary sets $\bar{x}$ and f where we assume f to be a function with $\mathrm{dom}(f) = \{\bar{x}\}$. Evidently then, the function value $f(\bar{x})$ exists uniquely, so that we may form the singleton $g = \{(\bar{x}, f(\bar{x}))\}$, which is an element of $\{f(\bar{x})\}^{\{\bar{x}\}}$ due to (3.536) and consequently a function with domain $\{\bar{x}\}$ according to (3.521). We now establish $f = g$ by means of the Equality Criterion for functions. To do this, we verify

$$\forall x\,(x \in \{\bar{x}\} \Rightarrow f(x) = g(x)), \tag{3.547}$$

letting x be arbitrary and assuming $x \in \{\bar{x}\}$ to be true, which assumption implies $x = \bar{x}$ with (2.169). Then, substitution yields $f(x) = f(\bar{x})$. Furthermore, $(\bar{x}, f(\bar{x})) \in g\ [= \{(\bar{x}, f(\bar{x}))\}]$ holds according to (2.153), which we may write also as $f(\bar{x}) = g(\bar{x})$, because g is a function. Thus, substitution gives $f(x) = g(\bar{x}) = g(x)$ and therefore the equation $f(x) = g(x)$. As x was arbitrary, we may infer from this finding the truth of the universal sentence (3.547), which in turn implies $f = g\ [= \{(\bar{x}, f(\bar{x}))\}]$, proving the proposed equation. Since $\bar{x}$ and f were also arbitrary, we may finally conclude that the proposition is true. □

The following set-theoretical axiom will be useful for defining functions in a more direct way than via the Axiom of Specification.

Axiom 3.2 (Axiom of Replacement). If, for any element x of a set X, there exists a unique y such that a given formula $\varphi(x, y)$ becomes a true sentence, then there exists a set Y such that, for any element x in X, there is an element y in Y for which $\varphi(x,y)$ becomes true, that is,

$$\forall x\,(x \in X \Rightarrow \exists! y\,(\varphi(x,y))) \Rightarrow \exists Y\,\forall x\,(x \in X \Rightarrow \exists y\,(y \in Y \,\wedge\, \varphi(x,y))). \tag{3.548}$$

Theorem 3.160 (Function definition by replacement). *For an arbitrary formula $\varphi(x,y)$ and any set X such that*

$$\forall x\,(x \in X \Rightarrow \exists! y\,(\varphi(x,y))) \tag{3.549}$$

holds, there exists a unique function f with domain X satisfying

$$\forall x\,(x \in X \Rightarrow \varphi(x, f(x))). \tag{3.550}$$

Proof. We let X be an arbitrary set satisfying (3.549) and prove first the existential part. With the Axiom of Replacement, the assumption (3.549) implies that there exists a set, say $\bar{Y}$, such that

$$\forall x\,(x \in X \Rightarrow \exists y\,(y \in \bar{Y} \,\wedge\, \varphi(x,y))) \tag{3.551}$$

holds. We then obtain with the Axiom of Specification and the Equality Criterion for sets

$$\exists! f\,\forall Z\,(Z \in f \Leftrightarrow [Z \in X \times \bar{Y} \,\wedge\, \exists x, y\,(\varphi(x,y) \,\wedge\, (x,y) = Z)]),$$

so that the set f satisfies

$$\forall Z\,(Z \in f \Leftrightarrow [Z \in X \times \bar{Y} \,\wedge\, \exists x, y\,(\varphi(x,y) \,\wedge\, (x,y) = Z)]). \tag{3.552}$$

Since $Z \in f$ implies in particular $Z \in X \times \bar{Y}$ for any Z, we obtain $f \subseteq X \times \bar{Y}$ with the definition of a subset, so that f is a binary relation. We now verify

$$\forall x\,(x \in X \Rightarrow \exists! y\,(y \in \bar{Y} \,\wedge\, (x,y) \in f)), \tag{3.553}$$

which will prove that f is a function from X to $\bar{Y}$, according to the Function Criterion (3.510). For this purpose, we let $\bar{x}$ be arbitrary in X and prove the uniquely existential sentence in (3.553), which is equivalent to the conjunction

$$\begin{aligned}&\exists y\,(y \in \bar{Y} \,\wedge\, (\bar{x},y) \in f)\\ &\quad \wedge\, \forall y, y'\,([y \in \bar{Y} \,\wedge\, (\bar{x},y) \in f \,\wedge\, y' \in \bar{Y} \,\wedge\, (\bar{x},y') \in f] \Rightarrow y = y')\end{aligned} \tag{3.554}$$

because of the Criterion for unique existence. Regarding the existential part, we first observe that $\bar{x} \in X$ implies with (3.551) that there exists an element of $\bar{Y}$, say $\bar{y}$, such that $\varphi(\bar{x},\bar{y})$ is true. Then, the conjunction of $\varphi(\bar{x},\bar{y})$ and $(\bar{x},\bar{y})=(\bar{x},\bar{y})$ is clearly true as well, so that the existential sentence

$$\exists x,y\,(\varphi(x,y)\ \wedge\ (x,y)=(x,y)) \tag{3.555}$$

holds. Because of $\bar{x}\in X$ and $\bar{y}\in\bar{Y}$, we have $(\bar{x},\bar{y})\in X\times\bar{Y}$ by definition of the Cartesian product. The conjunction of this and (3.555) then implies with (3.552) that $(\bar{x},\bar{y})\in f$. The conjunction of this and $\bar{y}\in\bar{Y}$ proves the existential part of (3.554). We now prove the uniqueness part. To do this, we let $\bar{y}$ and $\bar{y}'$ be arbitrary and assume $\bar{y}\in\bar{Y}$, $(\bar{x},\bar{y})\in f$, $\bar{y}'\in\bar{Y}$, and $(\bar{x},\bar{y}')\in f$. The second and fourth part of this conjunction imply with (3.552) in particular the two existential sentences

$$\exists x,y\,(\varphi(x,y)\ \wedge\ (x,y)=(\bar{x},\bar{y}))$$
$$\exists x,y\,(\varphi(x,y)\ \wedge\ (x,y)=(\bar{x},\bar{y}')).$$

Thus, there exist x and y, say x' and y' with $\varphi(x',y')$ and $(x',y')=(\bar{x},\bar{y})$, and there exist x and y, say x^* and y^* with $\varphi(x^*,y^*)$ and $(x^*,y^*)=(\bar{x},\bar{y}')$. Because of the Equality Criterion for ordered pairs, the two preceding equations imply $x'=\bar{x}$, $y'=\bar{y}$, $x^*=\bar{x}$, and $y^*=\bar{y}'$, so that substitution yields $\varphi(\bar{x},\bar{y})$ and $\varphi(\bar{x},\bar{y}')$. Since $\bar{x}\in X$ implies with (3.549) that there exists a unique y such that $\varphi(\bar{x},y)$ holds, we see that $y=\bar{y}=\bar{y}'$. As $\bar{y}$ and $\bar{y}'$ are arbitrary, we therefore conclude that uniqueness part and thus (3.554) is true. Since $\bar{x}$ was also arbitrary, we then further conclude that (3.553) holds, which implies with the Function Criterion that f is a function with domain X and codomain $\bar{Y}$.

It remains for us to show that f satisfies (3.550). Letting $\bar{x}$ be arbitrary in X, it follows with (3.553) that there exists a unique $\bar{y}\in\bar{Y}$ satisfying $(\bar{x},\bar{y})\in f$ (which we may write as $\bar{y}=f(\bar{x})$ with Notation 3.4). This implies with (3.552) in particular

$$\exists x,y\,(\varphi(x,y)\ \wedge\ (x,y)=(\bar{x},\bar{y})).$$

Thus, there are x and y, say x' and y', such that $\varphi(x',y')$ and $(x',y')=(\bar{x},\bar{y})$ are true. The latter equation implies $x'=\bar{x}$ and $y'=\bar{y}$ with 3.3, so that substitution gives us $\varphi(\bar{x},\bar{y})$. With the previously introduced notation $\bar{y}=f(\bar{x})$, we then obtain $\varphi(\bar{x},f(\bar{x})$. As $\bar{x}$ is arbitrary, we therefore conclude that f indeed satisfies 3.550).

We now prove the uniqueness part, letting f and f' be arbitrary functions with domain X such that they both satisfy (3.550). To show that this implies $f=f'$, we apply Method 3.2. To do this, we let x be an arbitrary element of X and show that this implies $f(x)=f'(x)$. Now, as f and f' satisfy (3.550), we see that $x\in X$ implies that $\varphi(x,f(x))$ and $\varphi(x,f'(x))$

are both true. Furthermore, $x \in X$ implies $\exists! y (\varphi(x, y))$, and therefore in particular (using the Criterion for unique existence)

$$\forall y, y' \, ([\varphi(x, y) \, \wedge \, \varphi(x, y')] \Rightarrow y = y').$$

With this, the conjunction of $\varphi(x, f(x))$ and $\varphi(x, f'(x))$ implies the desired $f(x) = f'(x)$; as x is arbitrary, we therefore conclude that $f = f'$ holds. Since f and f' were arbitrary, we then conclude that the uniqueness part of the proposed sentence holds as well, which completes the proof of the stated uniquely existential sentence.

Since X was also arbitrary, we finally conclude that the theorem is true. □

Method 3.3 (Function definition by replacement). To establish for a given set X and a given formula $\varphi(x, y)$ the unique existence of a function f with domain X such that f satisfies $\varphi(x, f(x))$ for any element x of the domain X, we may establish for any $x \in X$ the unique existence of an y satisfying $\varphi(x, y)$.

We demonstrate the application this method to define the following special function.

Theorem 3.161 (Existence of identity functions). *For any set X there exists a unique function* id_X *with domain X such that every element x of X is mapped to itself, i.e. such that*

$$\forall x \, (x \in X \Rightarrow \mathrm{id}_X(x) = x) \tag{3.556}$$

holds. Furthermore, the range of id_X *is identical with X.*

Proof. We let X be an arbitrary set and $\varphi(x, y)$ the formula $y = x$. Let us first verify the truth of

$$\forall x \, (x \in X \Rightarrow \exists! y \, (y = x)). \tag{3.557}$$

To do this, we let x be arbitrary, assume $x \in X$ to be true, and note that the uniquely existential sentence is true due to (1.109). Now, as x is arbitrary, it follows that (3.557) holds indeed. Then, it follows with Theorem 3.160 that there exists a unique function id_X with domain X satisfying

$$\forall x \, (x \in X \Rightarrow \varphi(x, \mathrm{id}_X(x))),$$

which is evidently equivalent to (3.556) for the given formula $\varphi(x, y)$.

We now prove $X = \mathrm{ran}(\mathrm{id}_X)$ by verifying the equivalent (using the Equality Criterion for sets)

$$\forall x \, (x \in X \Leftrightarrow x \in \mathrm{ran}(\mathrm{id}_X)). \tag{3.558}$$

For this purpose, we let x be arbitrary and assume first $x \in X$, which implies $\mathrm{id}_X(x) = x$ with (3.556), which we may write as $(x, x) \in \mathrm{id}_X$ according to Notation 3.4. Thus, there exists an a with $(a, x) \in \mathrm{id}_X$, which implies $x \in \mathrm{ran}(\mathrm{id}_X)$ with the definition of a range. This proves the first part ('$\Rightarrow$') of the equivalence in (3.558). We now assume $x \in \mathrm{ran}(\mathrm{id}_X)$ to be true, which implies that there exists a particular $\bar{x}$ with $(\bar{x}, x) \in \mathrm{id}_X$. Thus, there exists a b with $(\bar{x}, b) \in \mathrm{id}_X$, so that $\bar{x} \in \mathrm{dom}(\mathrm{id}_X)$ $[= X]$ by definition of a domain. Then, $\bar{x} \in X$ implies $\mathrm{id}_X(\bar{x}) = \bar{x}$ with (3.556). As the previously established $(\bar{x}, x) \in \mathrm{id}_X$ can be written as $\mathrm{id}_X(\bar{x}) = x$, we obtain from the previous two equations $x = \bar{x}$. With the latter equation, the previous finding $\bar{x} \in X$ implies $x \in X$, which proves the second part ('$\Leftarrow$') of the equivalence. Since x is arbitrary, we therefore conclude that (3.558) is true, so that $X = \mathrm{ran}(\mathrm{id}_X)$ holds, as claimed.

As X was also arbitrary, we finally conclude that the theorem is true. □

Definition 3.43 (Identity function). For any set X we call the function id_X which maps every element of its domain to itself in the sense of

$$\forall x\,(x \in X \Rightarrow \mathrm{id}_X(x) = x)$$

the *identity function* on X. We symbolize this function also by

$$\{(x, x) : x \in X\} \tag{3.559}$$

We may apply the Equality Criterion for functions to show that the identity function and the inclusion function on the same domain are set-theoretically identical.

Corollary 3.162. *For any sets X and Y it is true that the identity function on X and the inclusion map from X to Y are identical functions.*

Proof. Letting X and Y be arbitrary sets and observing that id_X and $j : X \to Y$ share the same domain X, we may now apply Method 3.2 to prove the stated equation. To do this, we verify

$$\forall x\,(x \in X \Rightarrow \mathrm{id}_X(x) = j(x)). \tag{3.560}$$

We let x be arbitrary and assume that $x \in X$ holds. We then obtain $\mathrm{id}_X(x) = x$ by definition of an identity function and $j(x) = x$ by definition of an inclusion map. Then, substitution yields $\mathrm{id}_X(x) = j(x)$, which proves the implication in (3.560). As x is arbitrary, we may therefore conclude that the universal sentence (3.560) holds, which then implies $\mathrm{id}_X = j$ with the Equality Criterion for functions (3.543). Since X and Y were arbitrary, we may then further conclude that the proposed universal sentence is true. □

Note 3.18. The identity function on a set X and the inclusion function from X to X are identical functions with identical codomains.

Proposition 3.163. *It is true for any sets X_1 and X_2 that there exists a unique function π_1 with domain $X_1 \times X_2$ such that*

$$\forall Z\,(Z \in X_1 \times X_2 \Rightarrow \exists x_1, x_2\,(Z = (x_1, x_2) \wedge \pi_1(Z) = x_1)) \tag{3.561}$$

holds. Moreover, X_1 is a codomain of this function.

Proof. Letting X_1 and X_2 be arbitrary sets, we apply Function definition by replacement and prove accordingly the universal sentence

$$\forall Z\,(Z \in X_1 \times X_2 \Rightarrow \exists! y\,(\exists x_1, x_2\,(Z = (x_1, x_2) \wedge y = x_1))). \tag{3.562}$$

For this purpose, we take an arbitrary set Z, and we assume that $Z \in X_1 \times X_2$ is true. By definition of the Cartesian product of two sets, there are then particular elements $\bar{x}_1 \in X_1$ and $\bar{x}_2 \in X_2$ with $(\bar{x}_1, \bar{x}_2) = Z$. Denoting here $\bar{x}_1$ by $\bar{y}$, we thus have the true existential sentence

$$\exists x_1, x_2\,(Z = (x_1, x_2) \wedge \bar{y} = x_1),$$

which demonstrates also the truth of the existential part of the uniquely existential sentence in (3.562). Regarding the uniqueness part, we apply Method 1.18 and take an arbitrary set y' satisfying the existential sentence

$$\exists x_1, x_2\,(Z = (x_1, x_2) \wedge y' = x_1).$$

This means that there are constants, say $\bar{x}_1'$ and $\bar{x}_2'$, for which $Z = (\bar{x}_1', \bar{x}_2')$ and $y' = \bar{x}_1'$ are satisfied. Recalling the truth of $(\bar{x}_1, \bar{x}_2) = Z$, we therefore obtain $\bar{x}_1' = \bar{x}_1$ and $\bar{x}_2' = \bar{x}_2$ with the Equality Criterion for ordered pairs. Then, substitution into the previously established $\bar{y} = \bar{x}_1$ gives us $\bar{y} = \bar{x}_1'$ $[= y']$. Since y' was arbitrary, we may infer from the resulting equation $\bar{y} = y'$ the truth of the uniqueness part of the uniquely existential sentence in (3.562). As Z was also arbitrary, we may further conclude that the universal sentence (3.562) holds, so that there exists indeed a unique function π_1 such that (3.561). To show that X_1 is a codomain of π_1, which means by definition that the inclusion $\mathrm{ran}(\pi_1) \subseteq X_1$ is true, we apply the definition of a subset and verify

$$\forall y\,(y \in \mathrm{ran}(\pi_1) \Rightarrow y \in X_1). \tag{3.563}$$

For this purpose, we let y be arbitrary, where we assume $y \in \mathrm{ran}(\pi_1)$ to be true. According to the definition of a range, there exists then a constant, say $\bar{Z}$, for which $(\bar{Z}, y) \in \pi_1$ is satisfied. Since π_1 is a function, we can apply function notation and write $y = \pi_1(\bar{Z})$; on the other hand, the definition of a domain yields $\bar{Z} \in X_1 \times X_2$. These findings imply now with the definition of the function π_1 in (3.561) that there exist particular constants $\bar{\bar{x}}_1, \bar{\bar{x}}_2$ such that $\bar{Z} = (\bar{\bar{x}}_1, \bar{\bar{x}}_2)$ and $\pi_1(\bar{Z}) = \bar{\bar{x}}_1$. Thus, substitution yields $(\bar{\bar{x}}_1, \bar{\bar{x}}_2) \in X_1 \times X_2$, with the consequence that

$$[y = \pi_1(\bar{Z}) =] \quad \bar{\bar{x}}_1 \in X_1$$

is true, by definition of the Cartesian product of two sets. The resulting $y \in X_1$ proves the implication in (3.563), in which y is arbitrary, so that the universal sentence (3.563) turns out to be true. Thus, the range of π_1 is included in X_1, and this means that X_1 is indeed a codomain of π_1. Because X_1 and X_2 were initially arbitrary sets, the proposition follows now to be true. □

Exercise 3.71. Show for any sets X_1 and X_2 that there exists a unique function π_2 with domain $X_1 \times X_2$ such that

$$\forall Z\,(Z \in X_1 \times X_2 \Rightarrow \exists x_1, x_2\,(Z = (x_1, x_2) \;\wedge\; \pi_2(Z) = x_2)) \tag{3.564}$$

holds. Verify then that X_2 is a codomain of this function.

Definition 3.44 (Projection function on the Cartesian product of two sets). We call for any sets X_1 and X_2 the functions $\pi_1 : X_1 \times X_2 \to X_1$ and $\pi_2 : X_1 \times X_2 \to X_2$, respectively, the *projection function* from $X_1 \times X_2$ to X_1 and from $X_1 \times X_2$ to X_2.

3.4.2. Restrictions and compositions of functions

Note 3.19. Since any function $f : X \to Y$ is a subset of $X \times Y$ according to (3.514), we see in light of (3.88) that the restriction of the function f to its domain X is the function f itself, that is,

$$\forall X, Y, f\,(f : X \to Y \;\Rightarrow\; f \restriction X = f). \tag{3.565}$$

Proposition 3.164. *For any function $f : X \to Y$ and any subset A of X the restriction $f \restriction A$ is a function from A to Y, that is,*

$$\forall X, Y, f, A\,([f \in Y^X \;\wedge\; A \subseteq X] \Rightarrow f \restriction A \in Y^A). \tag{3.566}$$

Proof. We let X, Y, f and A be arbitrary sets, assume that f is a function from X to Y, and assume furthermore that A is a subset of X. By definition of a restriction, $f \restriction A$ is a set of ordered pairs and therefore a binary relation. Thus, $f \restriction A$ satisfies Property 1 of a function. Regarding Property 2, we verify that $f \restriction A$ satisfies (3.504). For this purpose, we let x, y, y' be arbitrary, assume that $(x, y), (x, y') \in f \restriction A$ holds, and show that this implies $y = y'$. We see from (3.80) that $(x, y) \in f \restriction A$ implies in particular $(x, y) \in f$, and similarly that $(x, y') \in f \restriction A$ implies $(x, y') \in f$. As a function, f satisfies (3.504), so that the conjunction of $(x, y) \in f$ and $(x, y') \in f$ implies the desired $y = y'$. Thus, since y was arbitrary, we conclude that $f \restriction A$ satisfies also Property 2 of a function.

Next, we observe that f constitutes a binary relation with domain X. Then, the initial assumption $A \subseteq X$ [$= \mathrm{dom}(f)$] implies $\mathrm{dom}(f \restriction A) = A$ because of (3.106).

Finally, we show that $\mathrm{ran}(f \restriction A) \subseteq Y$ is also true, by verifying

$$\forall y \, (y \in \mathrm{ran}(f \restriction A) \Rightarrow y \in Y)$$

according to the definition of a subset. Letting $y \in \mathrm{ran}(f \restriction A)$ be arbitrary, it follows by definition of the range that there is an x, say $\bar{x}$, such that $(\bar{x}, y) \in f \restriction A$. The latter implies $(\bar{x}, y) \in f$ with (3.80), which shows that $y \in \mathrm{ran}(f)$. Since f satisfies (3.507), we have that $y \in \mathrm{ran}(f)$ implies the desired $y \in Y$ (by definition of a subset). Then, as y is arbitrary, we may conclude that $\mathrm{ran}(f \restriction A) \subseteq Y$ holds.

In summary, we thus proved that $f \restriction A : A \to Y$ holds, so that $f \restriction A$ is an element of Y^A. Since X, Y, f and A were arbitrary, the proposition follows then to be true. □

Corollary 3.165. *For any function $f : X \to Y$ and any subset A of X, it is true that the restriction of f to A takes the same value as f at any element of A, that is,*

$$\forall X, Y, f, A \, ([f \in Y^X \wedge A \subseteq X] \Rightarrow \forall x \, (x \in A \Rightarrow f \restriction A(x) = f(x))). \tag{3.567}$$

Proof. Letting X, Y, f and A be arbitrary, assuming $f : X \to Y$ and $A \subseteq X$ to be true, letting x be arbitrary in A, and letting the function value of $f \restriction A$ at x be $y = f \restriction A(x)$ (using the fact that this restriction is a function with domain A according to Proposition 3.164), we may write this equation as $(x, y) \in f \restriction A$. This in turn implies $(x, y) \in f$ with the definition of a restriction, which we may write also as $y = f(x)$. Then, substitution based on the previously established equation $y = f \restriction A(x)$ yields $f \restriction A(x) = f(x)$, as desired. Since x is arbitrary, we may therefore conclude that the universal sentence with respect to x is true. As X, Y, f and A were also arbitrary, we may further conclude that the proposed universal sentence holds. □

Proposition 3.166. *It is true for any set X, any partially ordered set $(Y, \leq_Y)$, any function $f : X \to Y$, any set $A \subseteq X$ and any element $a \in Y$ that a is a lower bound for $f \restriction A$ if a is a lower bound for f, i.e.*

$$\forall y\,(y \in \mathrm{ran}(f) \Rightarrow a \leq_Y y) \;\Rightarrow\; \forall y\,(y \in \mathrm{ran}(f \restriction A) \Rightarrow a \leq_Y y). \tag{3.568}$$

Proof. We let X, Y, $<_Y$, f, A and a be arbitrary, assume $(Y, <_Y)$ to be partially ordered, f to be a function from X to Y, A to be a subset of X and a to be an element of Y. To prove the stated implication directly, we also assume the universal sentence

$$\forall y\,(y \in \mathrm{ran}(f) \Rightarrow a \leq_Y y) \tag{3.569}$$

to be true, and we show that this implies

$$\forall y\,(y \in \mathrm{ran}(f \restriction A) \Rightarrow a \leq_Y y), \tag{3.570}$$

letting $\bar{y}$ be arbitrary and assuming $\bar{y} \in \mathrm{ran}(f \restriction A)$ to be true. Let us now observe that the range of the restriction $f \restriction A$ is included in the range of f according to Corollary 3.35, so that

$$\forall y\,(y \in \mathrm{ran}(f \restriction A) \Rightarrow y \in \mathrm{ran}(f))$$

follows to be true by definition of a subset. Therefore, the assumed $\bar{y} \in \mathrm{ran}(f \restriction A)$ implies $\bar{y} \in \mathrm{ran}(f)$, which in turn implies the desired $a \leq_Y y$ with (3.569). Thus, the proof of the implication in (3.570) is complete, and since y is arbitrary, we may infer from this the truth of the universal sentence (3.570). We thus completed also the proof of the implication (3.568), and because X, Y, $<_Y$, f, A and a were initially arbitrary, we may therefore conclude that the proposed universal sentence holds. □

Exercise 3.72. Show for any set X, any partially ordered set $(Y, \leq_Y)$, any function $f : X \to Y$, any set $A \subseteq X$ and any element $u \in Y$ that u is an upper bound for $f \restriction A$ if u is an upper bound for f, i.e.

$$\forall y\,(y \in \mathrm{ran}(f) \Rightarrow y \leq_Y u) \;\Rightarrow\; \forall y\,(y \in \mathrm{ran}(f \restriction A) \Rightarrow y \leq_Y u). \tag{3.571}$$

(Hint: Apply Corollary 3.35.)

Proposition 3.167. *For any function $f : X \to Y$ and any element x of X, it is true that the restriction of f to the singleton formed by x is identical with the constant function on that singleton with the value of f at x, i.e.*

$$\forall X, Y, f, x\,([f \in Y^X \,\wedge\, x \in X] \Rightarrow f \restriction \{x\} = \{(x, f(x))\}). \tag{3.572}$$

Proof. We let X, Y, f and $\bar{x}$ be arbitrary, assume $f \in Y^X$, so that $f : X \to Y$ holds, and assume furthermore $\bar{x} \in X$ to be true. As the latter implies $\{\bar{x}\} \subseteq X$ with (2.184), we may apply Proposition 3.164 to infer from the assumptions that $f \restriction \{\bar{x}\}$ is a function with domain $\{\bar{x}\}$. In view of Corollary 3.156, the singleton $g = \{(\bar{x}, f(\bar{x}))\}$ is also a function with domain $\{\bar{x}\}$, where the function value $f(\bar{x})$ is indeed specified because $\bar{x}$ is in the domain X of f. Let us now apply the Equality Criterion for functions to establish the desired equation $f \restriction \{\bar{x}\} = \{(\bar{x}, f(\bar{x}))\}$, by verifying

$$\forall x \, (x \in \{\bar{x}\} \Rightarrow f \restriction \{\bar{x}\}(x) = g(x)). \tag{3.573}$$

Letting x be arbitrary and assuming $x \in \{\bar{x}\}$, it now follows from $f \in Y^X$, the previously established $\{\bar{x}\} \subseteq X$ and the preceding assumption with (3.165) that $f \restriction \{\bar{x}\}(x) = f(x)$ holds. Since $x \in \{\bar{x}\}$ implies also $x = \bar{x}$ with (2.169) and since $g = \{(\bar{x}, f(\bar{x}))\}$ implies evidently $(\bar{x}, f(\bar{x})) \in g$, which we may write as $f(\bar{x}) = g(\bar{x})$, we obtain via substitution

$$[f \restriction \{\bar{x}\}(x) =] \quad f(x) = f(\bar{x}) = g(\bar{x}) = g(x).$$

This proves the implication in (3.573), and since x was arbitrary, we may therefore conclude that the universal sentence (3.573) holds. Thus, the functions $f \restriction \{\bar{x}\}$ and $\{(\bar{x}, f(\bar{x}))\}$ are indeed identical, and as X, Y, f and $\bar{x}$ were initially also arbitrary, we may infer from this the truth of the proposition. □

Proposition 3.168. *For any function $f : X \to Y$ it is true that removing an element (x, y) from f yields the restriction of f to the set difference of X and the singleton formed by x, i.e.*

$$\forall x, y \, ((x, y) \in f \Rightarrow f \restriction X \setminus \{x\} = f \setminus \{(x, y)\}). \tag{3.574}$$

Proof. We let X, Y, f, x and y be arbitrary, assume that f is a function from X to Y, and moreover that $(x, y) \in f$ is true. To show that this implies $f \restriction X \setminus \{x\} = f \setminus \{(x, y)\}$, we verify the equivalent (applying the Equality Criterion for sets)

$$\forall z \, (z \in f \restriction X \setminus \{x\} \Leftrightarrow z \in f \setminus \{(x, y)\}). \tag{3.575}$$

Letting z be arbitrary, we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $z \in f \restriction X \setminus \{x\}$. Then, by definition of a binary relation, there exist elements, say $\bar{x}$ and $\bar{y}$, with $(\bar{x}, \bar{y}) = z$, so that $(\bar{x}, \bar{y}) \in f \restriction X \setminus \{x\}$. Therefore, $\bar{x}$ is by definition an element of the domain $X \setminus \{x\}$ of the restriction $f \restriction X \setminus \{x\}$, which is a function in view of Proposition 3.164. It then follows from $\bar{x} \in X \setminus \{x\}$ that $\bar{x} \in X$ and $\bar{x} \notin \{x\}$ are both true, by definition of a set difference. The latter further implies $\bar{x} \neq x$ with (2.169), and therefore $(\bar{x}, \bar{y}) \neq (x, y)$ with the Equality Criterion for ordered pairs, so that we obtain $(\bar{x}, \bar{y}) \notin \{(x, y)\}$ again with (2.169). Now, $(\bar{x}, \bar{y}) \in f \upharpoonright X \setminus \{x\}$ also implies $(\bar{x}, \bar{y}) \in f$ by definition of a restriction. Thus, the conjunction of $(\bar{x}, \bar{y}) \in f$ and $(\bar{x}, \bar{y}) \notin \{(x, y)\}$ holds, so that the previously established equation $(\bar{x}, \bar{y}) = z$ gives $z \in f \setminus \{(x, y)\}$ (with the definition of a set difference). This proves the first part of the equivalence in (3.575).

To prove the second part ('$\Leftarrow$'), we now assume $z \in f \setminus \{(x, y)\}$ to be true and apply similar arguments as in the proof of the first part. Clearly then, $z \in f$ and $z \notin \{(x, y)\}$ both hold, and the latter implies $z \neq (x, y)$. Furthermore, $z \in f$ evidently implies that there exist elements, say $\bar{x}$ and $\bar{y}$, with $(\bar{x}, \bar{y}) = z$; thus, $(\bar{x}, \bar{y}) \in f$ as well as $(\bar{x}, \bar{y}) \neq (x, y)$. Let us now prove by contradiction that $\bar{x} \neq x$ is true. To do this, we assume $\neg \bar{x} \neq x$ to be true, which implies $\bar{x} = x$ with the Double Negation Law. With this equation, we obtain $(\bar{x}, \bar{y}) = (x, \bar{y})$, so that $(\bar{x}, \bar{y}) \in f$ implies $(x, \bar{y}) \in f$. Recalling that also $(x, y) \in f$, we have the true conjunction $(x, y) \in f \wedge (x, \bar{y}) \in f$, which implies $y = \bar{y}$ with the initial assumption that f is a function. This equation further implies $(x, \bar{y}) = (x, y)$; together with the equation $(\bar{x}, \bar{y}) = (x, \bar{y})$, this evidently yields $(\bar{x}, \bar{y}) = (x, y)$, which contradicts the previously established inequality $(\bar{x}, \bar{y}) \neq (x, y)$. This proves $\bar{x} \neq x$, so that $\bar{x} \notin \{x\}$. Moreover, the previously obtained $(\bar{x}, \bar{y}) \in f$ implies that $\bar{x}$ is an element of the domain X of f. Thus, the conjunction of $\bar{x} \in X$ and $\bar{x} \notin \{x\}$ holds, which means that $\bar{x} \in X \setminus \{x\}$. Then, the simultaneous truth of $(\bar{x}, \bar{y}) \in f$ and of $\bar{x} \in X \setminus \{x\}$ implies $(\bar{x}, \bar{y}) \in f \upharpoonright X \setminus \{x\}$ by definition of a restriction, which gives the desired $z \in f \upharpoonright X \setminus \{x\}$. This completes the proof of the equivalence in (3.575), and as z is arbitrary, we therefore conclude that the sets $f \upharpoonright X \setminus \{x\}$ and $f \setminus \{(x, y)\}$ are indeed identical. Since x, y, X, Y and f were also arbitrary, it follows that the proposition holds, as claimed. □

Proposition 3.169. *For any function $f : X \to Y$ and any elements $x_1, x_2 \in X$ it is true that the range of the restriction of f to the pair formed by x_1 and x_2 is identical with the pair formed by the corresponding function values $f(x_1)$ and $f(x_2)$, that is,*

$$\begin{aligned} &\forall X, Y, f, x_1, x_2\, ([f \in Y^X \wedge x_1, x_2 \in X] \\ &\quad \Rightarrow \operatorname{ran}(f \upharpoonright \{x_1, x_2\}) = \{f(x_1), f(x_2)\})). \end{aligned} \tag{3.576}$$

Proof. Letting X, Y, f, x_1 and x_2 be arbitrary, we assume $f \in Y^X$ and $x_1, x_2 \in X$ to be true, and we apply the Equality Criterion for sets to establish the stated equation. For this purpose, we verify

$$\forall y\,(y \in \operatorname{ran}(f \restriction \{x_1, x_2\}) \Leftrightarrow y \in \{f(x_1), f(x_2)\}). \tag{3.577}$$

We let y be arbitrary and we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in \operatorname{ran}(f \restriction \{x_1, x_2\})$ to be true. Then, there exists by definition of a range a constant, say $\bar{x}$, with $(\bar{x}, y) \in f \restriction \{x_1, x_2\}$. Since the assumed $x_1, x_2 \in X$ implies $\{x_1, x_2\} \subseteq X$ with Proposition 2.52, we have that $f \restriction \{x_1, x_2\}$ is a function with domain $\{x_1, x_2\}$ and codomain Y, according to Proposition 3.164. Consequently, we obtain $\bar{x} \in \{x_1, x_2\}$ (by definition of a domain), and we may write $y = f \restriction \{x_1, x_2\}(\bar{x})$, which yields $y = f(\bar{x})$ with (3.567). Here, $\bar{x} \in \{x_1, x_2\}$ also implies $\bar{x} = x_1 \vee \bar{x} = x_2$ with the definition of a pair, which disjunction we now use to prove

$$y = f(x_1) \vee y = f(x_2) \tag{3.578}$$

by cases. On the one hand, if $\bar{x} = x_1$ holds, then the previous established $y = f(\bar{x})$ yields $y = f(x_1)$ via substitution, so that the disjunction (3.578) is true. On the other hand, if $\bar{x} = x_2$ holds, then $y = f(\bar{x})$ gives $y = f(x_2)$, and the disjunction (3.578) is true again. This completes the proof by cases, and we may now infer from the truth of the disjunction (3.578) the truth of $y \in \{f(x_1), f(x_2)\}$ because of the definition of a pair. Thus, the first part of the equivalence in (3.577) holds.

To prove the second part ('$\Leftarrow$'), we now assume $y \in \{f(x_1), f(x_2)\}$ to be true, so that the disjunction (3.578) holds (by definition of a pair). We now carry out a proof by cases based on this disjunction to establish the desired consequent. In the first case $y = f(x_1)$, we may write $(x_1, y) \in f$. Since $x_1 \in \{x_1, x_2\}$ holds according to (2.151), we then obtain $(x_1, y) \in f \restriction \{x_1, x_2\}$ with the definition of a restriction. Therefore, the definition of a range yields the desired $y \in \operatorname{ran}(f \restriction \{x_1, x_2\})$ in the first case. Similarly, in the second case $y = f(x_2)$, we may write $(x_2, y) \in f$, which implies with $x_2 \in \{x_1, x_2\}$ that $(x_2, y) \in f \restriction \{x_1, x_2\}$ holds. Consequently, $y \in \operatorname{ran}(f \restriction \{x_1, x_2\})$ follows to be true also in the second case. This completes the proof of the equivalence in (3.577), and since y was arbitrary, we may therefore conclude that the universal sentence (3.577) is true. Then, the equation in (3.576) follows to be true with the Equality Criterion for sets, which in turn proves the implication in (3.576). As X, Y, f, x_1 and x_2 were initially arbitrary, we may now finally conclude that the proposition holds. □

Corollary 3.170. *For any functions f and g it is true that the restrictions of f and g to the intersection of their domains are functions from* $\operatorname{dom}(f) \cap \operatorname{dom}(g)$ *to the union* $\operatorname{ran}(f) \cup \operatorname{ran}(g)$ *of their ranges.*

Proof. Letting f and g be arbitrary functions, we see on the one hand with (2.74) that the inclusions

$$\operatorname{dom}(f) \cap \operatorname{dom}(g) \subseteq \operatorname{dom}(f)$$
$$\operatorname{dom}(f) \cap \operatorname{dom}(g) \subseteq \operatorname{dom}(g)$$

are true. On the other hand, it follows with (2.201) that the inclusions

$$\operatorname{ran}(f) \subseteq \operatorname{ran}(f) \cup \operatorname{ran}(g)$$
$$\operatorname{ran}(g) \subseteq \operatorname{ran}(f) \cup \operatorname{ran}(g)$$

hold, so that we may take $\operatorname{ran}(f) \cup \operatorname{ran}(g)$ for the codomain of both f and g. It then follows with Proposition 3.164 that

$$f \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g)) : \operatorname{dom}(f) \cap \operatorname{dom}(g) \to \operatorname{ran}(f) \cup \operatorname{ran}(g)$$
$$g \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g)) : \operatorname{dom}(f) \cap \operatorname{dom}(g) \to \operatorname{ran}(f) \cup \operatorname{ran}(g)$$

This is then true for any functions f and g. □

The preceding result gives rise to the following definition.

Definition 3.45 (Compatible functions, compatible set of functions). We say that

(1) any two functions f and g are *compatible* iff their restrictions to the intersection of their domains are identical, i.e. iff

$$f \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g)) = g \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g)). \tag{3.579}$$

(2) a set $\mathcal{F}$ of functions is *compatible* iff any two functions f and g in $\mathcal{F}$ are compatible, i.e. iff

$$\forall f, g\,(f, g \in \mathcal{F} \Rightarrow f \text{ and } g \text{ are compatible}). \tag{3.580}$$

Note 3.20. In view of Theorem 3.158, the equation (3.579) means that the function values of the restrictions $f \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g))$ and $g \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g))$ at any $x \in \operatorname{dom}(f) \cap \operatorname{dom}(g)$ are identical.

Corollary 3.171. *If two functions f and g are compatible, then g and f are also compatible.*

Proof. Letting f and g be arbitrary and assuming f and g to be compatible functions, we obtain the equations

$$\begin{aligned} g \upharpoonright (\operatorname{dom}(g) \cap \operatorname{dom}(f)) &= g \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g)) \\ &= f \upharpoonright (\operatorname{dom}(f) \cap \operatorname{dom}(g)) \\ &= f \upharpoonright (\operatorname{dom}(g) \cap \operatorname{dom}(f)) \end{aligned}$$

by applying the Commutative Law for the intersection of two sets, the definition of compatible functions, and then again the Commutative Law for the intersection of two sets. It then follows from these equations that g and f are compatible, by definition. As f and g were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

We now consider a situation in which two given functions are automatically compatible.

Proposition 3.172. *If a function f is a subset of a function g, then f and g are compatible functions.*

Proof. We let f and g be arbitrary functions and assume $f \subseteq g$, i.e. (by definition of a subset)

$$\forall z\,(z \in f \Rightarrow z \in g). \tag{3.581}$$

Since the restrictions in (3.579) share the same domain $X = \mathrm{dom}(f) \cap \mathrm{dom}(g)$ according to Corollary 3.170, we may now apply Method 3.2 to verify the equality of these restrictions. Thus, we verify

$$\forall x\,(x \in X \Rightarrow f \restriction X(x) = g \restriction X(x). \tag{3.582}$$

To do this, we let x be arbitrary in X and define

$$y = f \restriction X(x), \tag{3.583}$$

so that $(x, y) \in f \restriction X$. It then follows by definition of a restriction that $(x, y) \in f$, which further implies $(x, y) \in g$ with (3.581). This and $x \in X$ now imply $(x, y) \in g \restriction X$ (again by definition of a restriction), and therefore

$$y = g \restriction X(x). \tag{3.584}$$

The two equations (3.583) and (3.584) show that the equation in (3.582) holds for an arbitrary $x \in X$, so that the universal sentence (3.582) is true. This proves (3.579), which means that f and g are compatible. As f and g were arbitrary, we therefore conclude that the proposition holds, as claimed. □

The fact that any set is a subset of itself according to Proposition 2.4 naturally translates into the observation that any function is compatible with itself.

Corollary 3.173. *For any function f it is true that f and f are compatible.*

Proposition 3.174. *Any pair of compatible functions is compatible.*

Proof. Letting $\bar{f}$ and $\bar{g}$ be arbitrary and assuming $\bar{f}$ and $\bar{g}$ to be compatible functions, we form the pair $\{\bar{f}, \bar{g}\}$ and verify

$$\forall f, g\,(f, g \in \{\bar{f}, \bar{g}\} \Rightarrow f \text{ and } g \text{ are compatible}). \tag{3.585}$$

We let f and g be arbitrary and assume $f \in \{\bar{f}, \bar{g}\}$ as well as $g \in \{\bar{f}, \bar{g}\}$ to be true. These assumptions imply with the definition of a pair

$$f = \bar{f} \vee f = \bar{g} \tag{3.586}$$

as well as

$$g = \bar{f} \vee g = \bar{g}. \tag{3.587}$$

In case the first part $f = \bar{f}$ of the first disjunction and then, on the one hand, also the first part $g = \bar{f}$ of the latter assumption are true, we obtain $f = g$ via substitution, so that f and g are compatible due to Corollary 3.173. On the other hand, if the second part $g = \bar{g}$ of the second disjunction holds (alongside $f = \bar{f}$), it again follows that f and g are compatible since we assumed $\bar{f}$ and $\bar{g}$ to be compatible.

In case the second part $f = \bar{g}$ of the disjunction (3.586) and then, on the one hand, also the first part $g = \bar{f}$ of the disjunction (3.587) hold, the assumed compatibility of $\bar{f}$ and $\bar{g}$ implies the compatibility of g and f. Therefore, f and g follow again to be compatible with Corollary 3.171. If, on the other hand, $g = \bar{g}$ holds, we obtain from the case assumption $f = \bar{g}$ via substitution $f = g$, with the already demonstrated consequence that f and g are compatible.

We may infer from these findings that the implication in (3.585) is true, and since f and g are arbitrary, we may further conclude that the universal sentence (3.585) holds. Thus, the pair $\{\bar{f}, \bar{g}\}$ is compatible by definition, and as $\bar{f}$ and $\bar{g}$ were arbitrary, we may finally conclude that the proposition is true. □

Exercise 3.73. Show that, if the domains of two functions f and g are disjoint, then f and g are compatible functions.

(Hint: Apply (2.43) in connection with Corollary 3.170 and Proposition 3.164, and then Proposition 3.151.)

Theorem 3.175 (Concatenation of functions). *The following sentences are true for any compatible set $\mathcal{F}$ of functions.*

a) $\bigcup \mathcal{F}$ *is a function.*

b) Furthermore, there exists a unique set (system) $\mathcal{D}$ consisting of the domains of all the functions in $\mathcal{F}$ in the sense that

$$\forall D\,(D \in \mathcal{D} \Leftrightarrow \exists f\,(f \in \mathcal{F} \wedge \operatorname{dom}(f) = D)), \tag{3.588}$$

and the union of this set system is the domain of the union of $\mathcal{F}$, i.e.

$$\mathrm{dom}(\bigcup \mathcal{F}) = \bigcup \mathcal{D}. \tag{3.589}$$

Proof. We let $\mathcal{F}$ be an arbitrary set and assume that $\mathcal{F}$ is a compatible set of functions.

Concerning a), let us first observe that every element of $\bigcup \mathcal{F}$ is element of some element of $\mathcal{F}$ (by definition of the union of a set system). Furthermore, every element of $\mathcal{F}$ is a function and therefore a set of ordered pairs (by definition of a function). Thus, any element of $\bigcup \mathcal{F}$ is an ordered pair, so that $\bigcup \mathcal{F}$ is a binary relation and consequently satisfies Property 1 of a function. Regarding Property 2, we prove

$$\forall x, y, y' \, ([(x,y) \in \bigcup \mathcal{F} \wedge (x,y') \in \bigcup \mathcal{F}] \Rightarrow y = y'). \tag{3.590}$$

For this purpose, we let x, y and y' be arbitrary, assume $(x,y) \in \bigcup \mathcal{F}$ as well as $(x,y') \in \bigcup \mathcal{F}$, and demonstrate that $y = y'$ holds. With our initial observations, we have that (x,y) is an element of some element f of $\mathcal{F}$, say $\bar{f}$, and we have that (x,y') is an element of some element g of $\mathcal{F}$, say $\bar{g}$. Then, on the one hand, as there exists an y with $(x,y) \in \bar{f}$, we have $x \in \mathrm{dom}(\bar{f})$ (by definition of a domain); on the other hand, as there is an y' with $(x,y') \in \bar{g}$, we have $x \in \mathrm{dom}(\bar{g})$, so that

$$x \in \mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g}) \tag{3.591}$$

holds by definition of the intersection of pair. Then, as elements of $\mathcal{F}$, the functions $\bar{f}$ and $\bar{g}$ are compatible, so that

$$\bar{f} \upharpoonright (\mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g}))(x) = \bar{g} \upharpoonright (\mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g}))(x) \tag{3.592}$$

holds in view of Note 3.20. Now, $(x,y) \in \bar{f}$ and (3.591) imply

$$(x,y) \in \bar{f} \upharpoonright (\mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g}))$$

by definition of restriction; similarly, $(x,y') \in \bar{g}$ and (3.591) imply

$$(x,y') \in \bar{g} \upharpoonright (\mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g})).$$

Thus, the two equations

$$\bar{f} \upharpoonright (\mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g}))(x) = y$$
$$\bar{g} \upharpoonright (\mathrm{dom}(\bar{f}) \cap \mathrm{dom}(\bar{g}))(x) = y'$$

are true, so that (3.592) is equivalent to the desired $y = y'$. Since x, y and y' are arbitrary, we conclude that the binary relation $\bigcup \mathcal{F}$ is a function.

Concerning b), we may apply the Axiom of Specification and the Equality Criterion for sets to obtain the uniquely existential sentence

$$\exists! \mathcal{D} \forall D \, (D \in \mathcal{D} \Leftrightarrow [D \in \mathcal{P}(\bigcup\bigcup\bigcup \mathcal{F}) \wedge \exists f \, (f \in \mathcal{F} \wedge \mathrm{dom}(f) = D)]),$$

so that the set $\mathcal{D}$ satisfies

$$\forall D \, (D \in \mathcal{D} \Leftrightarrow [D \in \mathcal{P}(\bigcup\bigcup\bigcup \mathcal{F}) \wedge \exists f \, (f \in \mathcal{F} \wedge \mathrm{dom}(f) = D)]). \quad (3.593)$$

To show that $\mathcal{D}$ satisfies then also (3.588), we let D be arbitrary, and we prove the first part ('$\Rightarrow$') of the equivalence directly. The assumption $D \in \mathcal{D}$ implies then with (3.593) in particular the existential sentence in (3.588), so that the first part of the equivalence holds. To prove the second part ('$\Leftarrow$'), we now assume that existential sentence, i.e. we assume that there is an element of $\mathcal{F}$, say $\bar{f}$, with $\mathrm{dom}(\bar{f}) = D$. We now show that this implies the truth of $D \in \mathcal{P}(\bigcup\bigcup\bigcup \mathcal{F})$, by verifying first $D \subseteq \bigcup\bigcup\bigcup \mathcal{F}$. To do this, we apply the definition of a subset and prove the equivalent

$$\forall x \, (x \in D \Rightarrow x \in \bigcup\bigcup\bigcup \mathcal{F}). \quad (3.594)$$

Letting $\bar{x}$ be arbitrary and assuming $\bar{x} \in D$, so that $\bar{x} \in \mathrm{dom}(\bar{f})$, it follows with the definition of a domain that there exists an element, say $\bar{y}$, such that $(\bar{x}, \bar{y}) \in \bar{f}$ holds. Recalling $\bar{f} \in \mathcal{F}$, we thus see that there is an element $f \in \mathcal{F}$ with $(\bar{x}, \bar{y}) \in f$, so that

$$(\bar{x}, \bar{y}) \in \bigcup \mathcal{F} \quad (3.595)$$

follows to be true by definition of the union of a set system. According to the definition of an ordered pair, we have $(\bar{x}, \bar{y}) = \{\{\bar{x}\}, \{\bar{x}, \bar{y}\}\}$, and therefore $\{\bar{x}\} \in (\bar{x}, \bar{y})$ in view of (2.151). Together with (3.595), this shows that there exists a set $A \in \bigcup \mathcal{F}$ with $\{\bar{x}\} \in A$, so that we obtain (using again the definition of the union of a set system)

$$\{\bar{x}\} \in \bigcup\bigcup \mathcal{F}. \quad (3.596)$$

Since $\bar{x} \in \{\bar{x}\}$ is evidently also true, we see moreover that there is a set $A' \in \bigcup\bigcup \mathcal{F}$ with $\bar{x} \in A'$, and therefore we arrive at

$$\bar{x} \in \bigcup\bigcup\bigcup \mathcal{F}, \quad (3.597)$$

applying once more the definition of the union of a set system. We thus proved the implication in (3.594), and as $\bar{x}$ was arbitrary, we may infer from this the truth of (3.594). This universal sentence then gives (with the definition of a subset) $D \subseteq \bigcup\bigcup\bigcup\mathcal{F}$, which inclusion in turn yields $D \in \mathcal{P}(\bigcup\bigcup\bigcup\mathcal{F})$ (by definition of a power set). Together with the assumed existential sentence in (3.588), this further implies $D \in \mathcal{D}$ with (3.593), so that the proof of the implication ('$\Leftarrow$') in (3.588) is complete. Therefore, the equivalence in (3.588) is satisfied by D, and since D is arbitrary, we may now conclude that the universal sentence (3.588) is indeed true for $\mathcal{D}$.

Next, to prove the equation (3.589), we show that the equivalent

$$\forall x\,(x \in \mathrm{dom}(\bigcup\mathcal{F}) \Leftrightarrow x \in \bigcup\mathcal{D}) \tag{3.598}$$

holds (according to (2.18)). Letting x be arbitrary, we first assume $x \in \mathrm{dom}(\bigcup\mathcal{F})$. Then, there exists an element, say $\bar{y}$, with $(x,\bar{y}) \in \bigcup\mathcal{F}$. As noted before, the ordered pair $(x,\bar{y})$ is thus an element of some function f in $\mathcal{F}$, say of $\bar{f}$. Consequently, x is an element of the domain of $\bar{f}$. Because of $\bar{f} \in \mathcal{F}$ there exists an element of $\mathcal{D}$, say $\bar{D}$, with $\mathrm{dom}(\bar{f}) = \bar{D}$, so that $x \in \mathrm{dom}(\bar{f})$ implies $x \in \bar{D}$, Then, $\bar{D} \in \mathcal{D}$ and $x \in \bar{D}$ imply $x \in \bigcup\mathcal{D}$ (by definition of the union of a set system). This proves the first part of the equivalence in (3.598).

To prove the second part of that equivalence, we now assume $x \in \bigcup\mathcal{D}$, so that there exists an element of $\mathcal{D}$, say $\bar{D}$, with $x \in \bar{D}$. Since $\bar{D}$ is the domain of some function f in $\mathcal{F}$, say of $\bar{f}$, there exists an element, say $\bar{y}$, with $(x,\bar{y}) \in \bar{f}$. This and $\bar{f} \in \mathcal{F}$ imply $(x,\bar{y}) \in \bigcup\mathcal{F}$, so that x is an element of $\mathrm{dom}(\bigcup\mathcal{F})$.

This completes the proof of the equivalence, and since x is arbitrary, we conclude that (3.598) is true. Thus, the proposed equation (3.589) holds. As $\mathcal{F}$ was arbitrary, we finally conclude that the theorem holds, as claimed. □

Proposition 3.176. *It is true for any compatible functions $\bar{g}$ and $\bar{h}$ that their union constitutes a function with domain* $\mathrm{dom}(\bar{g}) \cup \mathrm{dom}(\bar{g})$.

Proof. We let $\bar{g}$ and $\bar{h}$ be arbitrary sets and assume these to be compatible functions, so that the pair $\{\bar{g},\bar{h}\}$ is a compatible set of functions by virtue of Proposition 3.174. This allows us to apply Concatenation of functions to define the new function $\bigcup\{\bar{g},\bar{h}\} = \bar{g} \cup \bar{h}$, and there exists a unique set $\mathcal{D}$ satisfying

$$\forall D\,(D \in \mathcal{D} \Leftrightarrow \exists f\,(f \in \{\bar{g},\bar{h}\} \,\wedge\, \mathrm{dom}(f) = D)) \tag{3.599}$$

and

$$\mathrm{dom}(\bar{g} \cup \bar{h}) = \bigcup\mathcal{D}. \tag{3.600}$$

We now prove by means of the Equality Criterion for sets that

$$\mathcal{D} = \{\mathrm{dom}(\bar{g}), \mathrm{dom}(\bar{g})\} \tag{3.601}$$

holds, by verifying accordingly the universal sentence

$$\forall D\,(D \in \mathcal{D} \Leftrightarrow D \in \{\mathrm{dom}(\bar{g}), \mathrm{dom}(\bar{g})\}). \tag{3.602}$$

We let D be an arbitrary set. Regarding the first part ('$\Rightarrow$') of the equivalence, we assume $D \in \mathcal{D}$ to be true, which implies with (3.599) that there exists a set, say $\bar{f}$, for which $\bar{f} \in \{\bar{g}, \bar{h}\}$ and $\mathrm{dom}(\bar{f}) = D$ are true. By definition of a pair, the disjunction $\bar{f} = \bar{g} \lor \bar{f} = \bar{h}$ holds then, too, which we now use to prove $D \in \{\mathrm{dom}(\bar{g}), \mathrm{dom}(\bar{g})\}$ by cases. Observing the truth of $\bar{g}, \bar{h} \in \{\bar{g}, \bar{h}\}$ in light of (2.151), we thus see that both the first case $\bar{f} = \bar{g}$ and the second case $\bar{f} = \bar{h}$ imply the desired consequent via substitution.

Concerning the second part ('$\Leftarrow$') of the equivalence in (3.602), we assume $D \in \{\mathrm{dom}(\bar{g}), \mathrm{dom}(\bar{g})\}$, so that the definition of a pair yields the true disjunction $D = \mathrm{dom}(\bar{g}) \lor D = \mathrm{dom}(\bar{h})$, so that we can prove $D \in \mathcal{D}$ by cases. Indeed, noting the truth of $\bar{g}, \bar{h} \in \{\bar{g}, \bar{h}\}$ in view of the previously mentioned (2.151), both the first case $D = \mathrm{dom}(\bar{g})$ and the second case $D = \mathrm{dom}(\bar{h})$ show that there exists an element $f \in \{\bar{g}, \bar{h}\}$ with $\mathrm{dom}(f) = D$, so that (3.599) gives the desired consequent in any case.

We thus completed the proof of the equivalence in (3.602), and as D was arbitrary, we may now infer from the truth of that equivalence the truth of the universal sentence (3.602), consequently also the truth of (3.601). Combining this equation with the equation (3.600), we therefore obtain

$$\mathrm{dom}(\bar{g} \cup \bar{h}) = \bigcup\{\mathrm{dom}(\bar{g}), \mathrm{dom}(\bar{g})\} = \mathrm{dom}(\bar{g}) \cup \mathrm{dom}(\bar{g}). \tag{3.603}$$

Here, $\bar{g}$ and $\bar{h}$ were initially arbitrary sets, so that the proposed universal sentence follows to be true. □

Proposition 3.177. *For any set X, any function f with domain X and any ordered pair (x, y) with $x \notin X$ it is true that $f \cup \{(x, y)\}$ is a function with domain $X \cup \{x\}$.*

Proof. We let X, f, x and y be arbitrary, assume that f is a function with $\mathrm{dom}(f) = X$, and assume moreover that $x \notin X$ holds. The latter assumption implies with (2.173) that X and $\{x\}$ are disjoint sets. Furthermore, as the singleton $\{(x, y)\}$ is a function with domain $\{x\}$ according to Corollary 3.156, we have that f and $\{(x, y)\}$ are functions with disjoint domains. Consequently, f and $\{(x, y)\}$ are compatible functions according to Exercise 3.73. It now follows with Proposition 3.176 that the union $f \cup \{(x, y)\}$ is a function with domain $X \cup \{x\}$. As X, f, x and y were arbitrary, we may therefore conclude that the proposed universal sentence holds. □

We now study compositions of functions.

Proposition 3.178. *For any functions $f : X \to Y$ and $g : Y \to Z$ the composition of g and f is a function from X to Z, that is,*

$$\forall f, g\,([f \in Y^X \wedge g \in Z^Y] \Rightarrow g \circ f \in Z^X). \tag{3.604}$$

Proof. We let X, Y, f and g be arbitrary sets and assume $f : X \to Y$ as well as $g : Y \to Z$ to be true. Since the functions f and g are then by definition binary relations where the domain of f equals X, we obtain $\mathrm{dom}(g \circ f) = X$ with (3.130). Next, we prove that the binary relation $g \circ f$ is a function, by verifying

$$\forall x, z, z'\,([(x, z) \in g \circ f \wedge (x, z') \in g \circ f] \Rightarrow z = z'). \tag{3.605}$$

For this purpose, we let x, z and z' be arbitrary and assume $(x, z) \in g \circ f$ as well as $(x, z') \in g \circ f$. By definition of a composition, $(x, z) \in g \circ f$ implies that there exist elements, say $\bar{x}$, $\bar{y}$ and $\bar{z}$ with $(\bar{x}, \bar{y}) \in f$, $(\bar{y}, \bar{z}) \in g$ and $(\bar{x}, \bar{z}) = (x, z)$; the latter equation implies $\bar{x} = x$ and $\bar{z} = z$ with the Equality Criterion for ordered pairs, so that substitution yields $(x, \bar{y}) \in f$ and $(\bar{y}, z) \in g$. Similarly, $(x, z') \in g \circ f$ implies that there exist elements, say $\bar{a}$, $\bar{b}$ and $\bar{c}$ with $(\bar{a}, \bar{b}) \in f$, $(\bar{b}, \bar{c}) \in g$ and $(\bar{a}, \bar{c}) = (x, z')$; the latter equation gives (again with the Equality Criterion for ordered pairs) $\bar{a} = x$ and $\bar{c} = z'$, which equations yield $(x, \bar{b}) \in f$ and $(\bar{b}, z') \in g$. Now, since f is a function, the conjunction of the previously found $(x, \bar{y}) \in f$ and $(x, \bar{b}) \in f$ implies $\bar{y} = \bar{b}$. With this equation, $(\bar{b}, z') \in g$ becomes $(\bar{y}, z') \in g$; together with the previously obtained $(\bar{y}, z) \in g$, this implies $z = z'$, because g is also a function. Since x, z and z' are arbitrary, we may therefore conclude that (3.605) holds. Thus, the binary relation $g \circ f$ satisfies also Property 2 of a function.

Furthermore, it follows with (3.133) that $\mathrm{ran}(g \circ f) \subseteq \mathrm{ran}(g)$ holds. Observing now that the assumption $g : Y \to Z$ implies $\mathrm{ran}(g) \subseteq Z$ by definition of a codomain, we obtain from these two inclusions $\mathrm{ran}(g \circ f) \subseteq Z$ with the transitivity of $\subseteq$. Thus, Z is a codomain of $g \circ f$, which completes the proof that $g \circ f$ is a function from X to Z. □

Notation 3.6. When f and g are functions, we write

$$x \mapsto (g \circ f)(x) \quad \text{or} \quad x \mapsto g(f(x)). \tag{3.606}$$

The latter is justified since every $x \in \mathrm{dom}(f)$ is mapped by f into a unique $y \in \mathrm{dom}(g)$ due to (3.604), which y in turn is mapped by g into a unique $z \in \mathrm{ran}(g)$, which z coincides with $(g \circ f)(x)$ by definition of a composition.

Certain functions do not alter a given function when composed with. For the following definition, we apply (3.604) to a transformation $t : X \to X$ and a function $f : X \to Y$.

Definition 3.46 (Invariant (function)). For any sets X and Y, for any function $f : X \to Y$,

(1) and for any transformation t on X, we say that f is (*an*) *invariant under* t iff the composition of f and t is identical with f, i.e., iff

$$f \circ t = f. \tag{3.607}$$

(2) and for any subset $\mathcal{T}$ of the set X^X of transformations on X, we say that f is (*an*) *invariant under* $\mathcal{T}$ iff f is invariant under any of the transformations in G, i.e., iff

$$\forall t\, (t \in \mathcal{T} \Rightarrow f \circ t = f). \tag{3.608}$$

Note 3.21. In view of the Equality Criterion for functions and Notation 3.6, the definite property (3.607) of an invariant function (under a transformation t) can also be stated as

$$\forall x\, (x \in X \Rightarrow f(t(x)) = f(x)). \tag{3.609}$$

Corollary 3.179. *It is true for any sets X and Y that the empty function $\emptyset : \emptyset \to Y$ is invariant under any transformation $t : X \to X$ and under any subset $\mathcal{T}$ of the set X^X of transformations on X.*

Proof. Letting X and Y be arbitrary sets and $t : X \to X$ an arbitrary transformation on X, we observe in light of Corollary 3.39 that $\emptyset \circ t = \emptyset$ holds. Since t is arbitrary we may therefore conclude that $\emptyset : \emptyset \to Y$ is invariant under any $t : X \to X$. Letting now $\mathcal{T}$ be an arbitrary subset of X^X and t an arbitrary element of $\mathcal{T}$, we find $t \in X^X$ with the definition of a subset, so that $t : X \to X$. Thus, the previously established equation $\emptyset \circ t = \emptyset$ applies, and as t was arbitrary, we may therefore conclude that $\emptyset : \emptyset \to Y$ is invariant under $\mathcal{T}$. Since X and Y are also arbitrary, we may then further conclude that the stated universal sentence holds. □

Theorem 3.180 (Neutrality of identity functions under composition). *Any function f from a set X to a set Y is identical both with the composition of f and the identity function on X and with the composition of the identity function on Y and f, that is,*

$$\forall X, Y, f\, (f : X \to Y \Rightarrow [f \circ \mathrm{id}_X = f \wedge \mathrm{id}_Y \circ f = f]). \tag{3.610}$$

Exercise 3.74. Establish the neutrality of identity functions under composition.

(Hint: Apply Method 3.2 with Notation 3.6 and Definition 3.43.)

Note 3.22. The Neutrality of identity functions under composition and the fact that the identity function id_X is a function from X to X (see Theorem 3.161) and thus a transformation on X imply in particular that every function $f : X \to Y$ is invariant under id_X.

Exercise 3.75. Show for any set X, any constant c and any subset $\mathcal{T}$ of the set X^X of transformations on X that the constant function g_c on X with value c is an invariant under $\mathcal{T}$.

(Hint: Apply the Equality Criterion for functions in connection with Notation 3.6 and (3.534).)

A restriction of a function can be expressed as the composition of the function and the inclusion function on the restricting set.

Proposition 3.181. *For any function $f : X \to Y$ and any subset A of X, the restriction of f to A is the composition of f and the inclusion function j from A to X, that is,*

$$\forall X, Y, f, A\,([f : X \to Y \,\wedge\, A \subseteq X] \Rightarrow f \restriction A = f \circ j). \tag{3.611}$$

Proof. We let X and Y be arbitrary sets, f an arbitrary function from X to Y, A an arbitrary subset of X, and we let $j : A \to X$ be the inclusion function from the subset A to X. Then, the restriction $f \restriction A$ is a function with domain A due to Proposition 3.164, and the composition $f \circ j$ is a function also with domain A according to Proposition 3.178. Thus, the function $f \restriction A$ and $f \circ j$ share the same domain A, so that we may apply Method 3.2 based on the Equality Criterion for functions to establish the equation $f \restriction A = f \circ j$. To do this, we verify

$$\forall x\,(x \in A \Rightarrow (f \restriction A)(x) = (f \circ j)(x)), \tag{3.612}$$

letting x be arbitrary and assuming $x \in A$ to be true. We then obtain the true equations

$$(f \circ j)(x) = f(j(x)) = f(x) = (f \restriction A)(x)$$

with Notation 3.6, the definition of an inclusion function, and (3.567). Therefore, the equation $(f \restriction A)(x) = (f \circ j)(x)$ follows to be true, and since x is arbitrary, we may therefore conclude that the universal sentence (3.612) holds. Since X, Y, f and A were initially arbitrary we may then further conclude that (3.611) holds, as proposed. □

Theorem 3.182 (Associative Law for function composition). *The composition of functions is associative in the sense that*

$$\forall f, g, h\,([f \in Y^X \,\wedge\, g \in Z^Y \,\wedge\, h \in A^Z] \Rightarrow [h \circ g] \circ f = h \circ [g \circ f]). \tag{3.613}$$

Proof. We let X, Y, Z, A, f and g be arbitrary sets and assume that $f : X \to Y$, $g : Y \to Z$ and $h : Z \to A$. Let us first observe in light of Proposition 3.178 that

$$\begin{aligned} h \circ g &\in A^Y, \\ (h \circ g) \circ f &\in A^X, \\ g \circ f &\in Z^X, \\ h \circ (g \circ f) &\in A^X. \end{aligned}$$

Thus, $(h \circ g) \circ f$ and $h \circ (g \circ f)$ are both functions with the same domain X and the same codomain A. We now verify by means of Method 3.2 that the functions themselves are identical. Letting x be an arbitrary element of the domain X, we observe in light of Notation 3.6 that

$$\begin{aligned} ((h \circ g) \circ f)(x) &= (h \circ g)(f(x)) = h(g(f(x))) = h((g \circ f)(x)) \\ &= (h \circ (g \circ f))(x). \end{aligned}$$

We thus conclude that the proposed equation (3.613) holds. As X, Y, Z, A, f, g and h were arbitrary, we conclude that the theorem is true. □

Proposition 3.183. *It is true for any sets X, Y and Z, any subset $\mathcal{T}$ of the set X^X of transformations of X, any invariant $f : X \to Y$ under $\mathcal{T}$ and any function $h : Y \to Z$ that the composition $h \circ f$ is also an invariant under $\mathcal{T}$.*

Proof. We take arbitrary sets X and Y, an arbitrary subset $\mathcal{T} \subseteq X^X$, an arbitrary invariant $f : X \to Y$ under $\mathcal{T}$, an arbitrary function $h : Y \to Z$, and an arbitrary element $t \in \mathcal{T}$. The latter implies with the definition of a subset that $t \in X^X$, so that $t : X \to X$. We then obtain the compositions $h \circ f : X \to Z$ and $(h \circ f) \circ t : X \to Z$ with Proposition 3.178. Moreover, we obtain the equations

$$(h \circ f) \circ t = h \circ (f \circ t) = h \circ f$$

by using the Associative Law for function composition and the assumption that f is invariant under $\mathcal{T}$, so that $f \circ t = f$ is true. Since t was arbitrary, we may therefore conclude that $h \circ f$ is indeed an invariant under $\mathcal{T}$, by definition. As X, Y, Z, $\mathcal{T}$, f and h were initially also arbitrary, we may further conclude that the stated universal sentence is true. □

3.4.3. Injections, surjections, and bijections

Definition 3.47 (Injection, one-to-one function). We say that a function $f : X \to Y$ is *one-to-one* or an *injection*, symbolically

$$f : X \hookrightarrow Y, \tag{3.614}$$

iff the identity of function values implies identity of arguments, i.e. iff

$$\forall x, x' \,([x, x' \in X \wedge f(x) = f(x')] \Rightarrow x = x'). \tag{3.615}$$

Corollary 3.184. *The singleton formed by a pair (x, y) is an injection from the singleton formed by x to the singleton formed by y, that is,*

$$\forall x, y\,(\{(x, y)\} : \{x\} \hookrightarrow \{y\}). \tag{3.616}$$

Proof. We let $\bar{x}$ and $\bar{y}$ be arbitrary and recall from Corollary 3.156 that the singleton $\{(\bar{x}, \bar{y})\}$ is a function from $\{\bar{x}\}$ to $\{\bar{y}\}$. We now verify that $f = \{(\bar{x}, \bar{y})\}$ satisfies

$$\forall x, x' \,([x, x' \in \{\bar{x}\} \wedge f(x) = f(x')] \Rightarrow x = x'). \tag{3.617}$$

We let x and x' be arbitrary, assume $x, x' \in \{\bar{x}\}$ as well as $f(x) = f(x')$ to be true, and observe that the former assumption implies the equations $x = \bar{x}$ and $x' = \bar{x}$ with (2.169), so that substitution gives already the desired consequent $x = x'$. As x and x' are arbitrary, we may therefore conclude that (3.617) holds, so that $\{(\bar{x}, \bar{y})\} : \{\bar{x}\} \hookrightarrow \{\bar{y}\}$ follows to be true by definition of an injection. Since $\bar{x}$ and $\bar{y}$ were also arbitrary, we may infer from this the truth of the proposed universal sentence. $\square$

Exercise 3.76. Show for any set Y that the function $\emptyset : \emptyset \to Y$ is an injection, i.e.

$$\emptyset : \emptyset \hookrightarrow Y, \tag{3.618}$$

and show that this is the only injection from $\emptyset$ to Y.

Theorem 3.185 (Injection Criterion). *For any set X it is true that a function f with domain X is an injection iff distinct elements of the domain X are associated with distinct function values, i.e. iff*

$$\forall x, x' \,([x, x' \in X \wedge x \neq x'] \Rightarrow f(x) \neq f(x')). \tag{3.619}$$

Exercise 3.77. Prove the Injection Criterion and show furthermore for any set X that a function f with domain X is not an injection iff there are distinct elements of the domain which are mapped to the same value, i.e. iff

$$\exists x, x' \,(x, x' \in X \wedge x \neq x' \wedge f(x) = f(x')). \tag{3.620}$$

(Hint: Concerning the proof of the Injection Criterion, apply (1.49) and (1.19).)

Combining the Injection Criterion with the fact that two distinct function values cannot have identical arguments for any kind of function according to Proposition 3.149, we immediately obtain the following result.

Corollary 3.186. *For any set X and any injection f with domain X it is true that two elements of the domain are different iff the corresponding function values are different, i.e.*

$$\forall x, x' \, (x, x' \in X \Rightarrow [x \neq x' \Leftrightarrow f(x) \neq f(x')]). \tag{3.621}$$

Note 3.23. As the codomain Y does not occur in the definite property (3.615), we see that whether a given function is one-to-one or not is independent of the choice for the codomain.

The following exercise may clarify this fact.

Exercise 3.78. Verify the following sentences for any injection $f : X \to Y$.

a) f is also a one-to-one function from X to its range, that is,

$$\forall X, Y, f \, (f : X \hookrightarrow Y \;\Rightarrow\; f : X \hookrightarrow \mathrm{ran}(f)). \tag{3.622}$$

(Hint: Use (3.518).)

b) If Y is subset of a set Z, then f is also a one-to-one function from X to Z, that is,

$$\forall X, Y, f, Z \, ([f : X \hookrightarrow Y \wedge Y \subseteq Z] \Rightarrow f : X \hookrightarrow Z). \tag{3.623}$$

(Hint: Use (3.519).)

Proposition 3.187. *The restriction of an injection to a subset of the domain is also an injection, that is,*

$$\forall X, Y, f, A \, ([f : X \hookrightarrow Y \wedge A \subseteq X] \Rightarrow f \restriction A : A \hookrightarrow Y). \tag{3.624}$$

Proof. We let $f : X \hookrightarrow Y$ be an arbitrary injection and A an arbitrary subset of X. We first note that $f \restriction A$ is a function with domain A and codomain Y due to Proposition 3.164. To verify that $f \restriction A$ satisfies (3.615), we let x, x' be arbitrary, assume that $x, x' \in A$ and $f \restriction A(x) = f \restriction A(x')$ are true, and show that this implies $x = x'$. Let us define $y = f \restriction A(x)$ $(= f \restriction A(x'))$. Now, $x, x' \in A$ implies $x, x' \in X$ due to $A \subseteq X$ and the definition of a subset. Therefore, the fact $(x, y), (x', y) \in f \restriction A$ implies $(x, y), (x', y) \in f$ (by definition of a restriction), which means that $f(x) = f(x')$. As an injection, f satisfies (3.615), so that the conjunction of $x, x' \in X$ and $f(x) = f(x')$ implies the desired $x = x'$. We thus proved that $f \restriction A$ is an injection (from A to Y). As f and A were arbitrary, we conclude that the proposition is true. $\square$

Proposition 3.188. *For any subset X of a set Y the inclusion function from X to Y is one-to-one, that is,*

$$\forall X, Y\,(X \subseteq Y \Rightarrow j : X \hookrightarrow Y). \tag{3.625}$$

Proof. We let Y be an arbitrary set, X an arbitrary subset of Y, and verify (3.615) for $f = j$. For this purpose, we let x, x' be arbitrary and assume that $x, x' \in X$ and $j(x) = j(x')$ are true. This implies $(x, y), (x', y) \in j$ with $y = j(x) = j(x')$. By definition of the inclusion function, $x = y$ and $x' = y$ are then true, so that we obtain the desired $x = x'$ with substitution. Since x and x' are arbitrary, we conclude that the inclusion function j is one-to-one. □

Note 3.18 applies immediately to the preceding finding.

Corollary 3.189. *The identity function on any set X is one-to-one, that is,*

$$\forall X\,(\mathrm{id}_X : X \hookrightarrow X). \tag{3.626}$$

Theorem 3.190 (Injectivity of the composition of two injections). *It is true that the composition of an injection g from a set Y to a set Z and an injection f from a set X to Y is itself an injection from X to Z, i.e.*

$$\forall X, Y, Z, f, g\,([f : X \hookrightarrow Y \,\wedge\, g : Y \hookrightarrow Z] \Rightarrow g \circ f : X \hookrightarrow Z). \tag{3.627}$$

Proof. We let X, Y and Z be arbitrary sets, f an arbitrary injection from X to Y, and g an arbitrary injection from Y to Z. Let us now observe in light of (3.604) that the composition $g \circ f$ is a function from X to Z. To prove that $g \circ f$ is an injection, we show according to (3.615) that

$$\forall x, x'\,([x, x' \in X \,\wedge\, (g \circ f)(x) = (g \circ f)(x')] \Rightarrow x = x') \tag{3.628}$$

holds. For this purpose, let $\bar{x}$ and $\bar{x}'$ be arbitrary elements of X such that $(g \circ f)(\bar{x}) = (g \circ f)(\bar{x}')$ is true, which equation we may write also as $g(f(\bar{x})) = g(f(\bar{x}'))$. Let us now use the denotations $\bar{y} = f(\bar{x})$ and $\bar{y}' = f(\bar{x}')$, so that the preceding equations give $g(\bar{y}) = g(\bar{y}')$ via substitution. As we may write the equations $\bar{y} = f(\bar{x})$ and $\bar{y}' = f(\bar{x}')$ also as $(\bar{x}, \bar{y}) \in f$ and $(\bar{x}', \bar{y}') \in f$, we see on the one hand that there exists an x with $(x, \bar{y}) \in f$, so that $\bar{y} \in \mathrm{ran}(f)$ follows to be true by definition of a range. On the other hand, we see that there is an x' with $(x', \bar{y}') \in f$, and therefore $\bar{y}' \in \mathrm{ran}(f)$ also holds (by definition of a range). As f was assumed to be a function with codomain Y, we have that $\mathrm{ran}(f) \subseteq Y$ is true. Consequently, the previously established $\bar{y}, \bar{y}' \in \mathrm{ran}(f)$ imply with the definition of a subset $\bar{y}, \bar{y}' \in Y$. Together with the previously obtained $g(\bar{y}) = g(\bar{y}')$, this implies then $\bar{y} = \bar{y}'$, because g was assumed to be an injection with domain Y. Then, substitution based on this equation yields

$$f(\bar{x}) = \bar{y} = \bar{y}' = f(\bar{x}')$$

and therefore $f(\bar{x}) = f(\bar{x}')$. Then, in view of $\bar{x}, \bar{x}' \in X$ and the assumption that f is an injection with domain X, this equation implies $\bar{x} = \bar{x}'$. Since $\bar{x}$ and $\bar{x}'$ are arbitrary, we may therefore conclude that (3.628) holds, which shows that the function $g \circ f : X \to Z$ is indeed an injection. As X, Y, Z, f and g were also arbitrary, we may then further conclude that the proposed universal sentence (3.627) is true. □

Another type of function is characterized by the property that the function values fill up the entire codomain.

Definition 3.48 (Surjection, onto function). We say that a function $f : X \to Y$ is a *surjection* from X to Y or a function from X *onto* Y, symbolically

$$f : X \twoheadrightarrow Y, \tag{3.629}$$

iff the range of f is identical with Y, that is, iff

$$\mathrm{ran}(f) = Y. \tag{3.630}$$

Corollary 3.191. *A function f is onto a set Y iff any element y is in Y precisely when y is function value at some x, that is,*

$$\forall Y, f\,(f \text{ is a function} \Rightarrow [f : \mathrm{dom}(f) \twoheadrightarrow Y \;\Leftrightarrow \forall y\,(y \in Y \Leftrightarrow \exists x\,(f(x) = y))]). \tag{3.631}$$

Proof. Letting Y and f be arbitrary and assuming f to be a function, we notice the truth of the equivalence

$$Y = \mathrm{ran}(f) \;\Leftrightarrow\; \forall y\,(y \in Y \Leftrightarrow \exists x\,(f(x) = y)) \tag{3.632}$$

in light of the definition of a range, applying Notation 3.4. With this, the equivalence in (3.631) follows to be true. Since Y and f are arbitrary, we may therefore conclude that the proposed universal sentence (3.631) holds. □

Exercise 3.79. Show that the function $\emptyset : \emptyset \to \emptyset$ is a surjection, i.e.

$$\emptyset : \emptyset \twoheadrightarrow \emptyset, \tag{3.633}$$

and show that this is the only surjection from $\emptyset$ to $\emptyset$.
(Hint: Apply Proposition 3.118.)

Theorem 3.192 (Surjection Criterion). *A function f with codomain Y is onto Y iff any element y in Y is function value at some x, that is,*

$$\forall Y, f\,(f : \mathrm{dom}(f) \to Y \\ \Rightarrow\ [f : \mathrm{dom}(f) \twoheadrightarrow Y \ \Leftrightarrow\ \forall y\,(y \in Y \Rightarrow \exists x\,(f(x) = y))]). \tag{3.634}$$

Proof. We let Y and f be arbitrary and assume $f : \mathrm{dom}(f) \to Y$ to be true. To prove the first part ('⇒') of the stated equivalence, we further assume $f : \mathrm{dom}(f) \twoheadrightarrow Y$, so that $\mathrm{ran}(f) = Y$ holds by definition of a surjection. This equation implies

$$\forall y\,(y \in \mathrm{ran}(f) \Leftrightarrow y \in Y) \tag{3.635}$$

with the Equality Criterion for sets. Now, to prove the desired consequent of '⇒'

$$\forall y\,(y \in Y \Rightarrow \exists x\,(f(x) = y)), \tag{3.636}$$

we let $\bar{y}$ be arbitrary and assume that $\bar{y} \in Y$ is true. This assumption implies with (3.635) $\bar{y} \in \mathrm{ran}(f)$, so that – by definition of a range – there exists an element, say $\bar{x}$, such that $(\bar{x}, \bar{y}) \in f$ holds. As we initially assumed f to be a function, we may write this also as $\bar{y} = f(\bar{x})$, which shows that the existential sentence in (3.636) is true. As $\bar{y}$ was arbitrary, we may therefore conclude that the universal sentence (3.636) holds, completing the proof of the first part of the equivalence in (3.634).

We now prove the second part ('⇒') of the equivalence, assuming the universal sentence (3.636) to be true. To show that this implies $f : \mathrm{dom}(f) \twoheadrightarrow Y$, we verify $\mathrm{ran}(f) = Y$. For this purpose, we establish $\mathrm{ran}(f) \subseteq Y$ and $Y \subseteq \mathrm{ran}(f)$, which will then imply the preceding equation with the Axiom of Extension. Let us here observe that the first inclusion $\mathrm{ran}(f) \subseteq Y$ is true because f is by assumption a function with codomain Y. To prove the second inclusion $Y \subseteq \mathrm{ran}(f)$, we apply the definition of a subset and verify the equivalent

$$\forall y\,(y \in Y \Leftrightarrow y \in \mathrm{ran}(f)). \tag{3.637}$$

Letting $\bar{y}$ be arbitrary and assuming $\bar{y} \in Y$ to hold, it follows with the assumed (3.636) that there is an element, say $\bar{x}$, with $f(\bar{x}) = \bar{y}$. We may write this also as $(\bar{x}, \bar{y}) \in f$, which shows that there exists an x such that $(x, \bar{y}) \in f$, and therefore $\bar{y} \in \mathrm{ran}(f)$ follows to be true by definition of a range. This proves the implication in (3.637), and since $\bar{y}$ is arbitrary, we may infer from this the truth of (3.637) and thus the truth of the equivalent $Y \subseteq \mathrm{ran}(f)$. This completes the proof of the conjunction $\mathrm{ran}(f) \subseteq Y \wedge Y \subseteq \mathrm{ran}(f)$, so that the equation $\mathrm{ran}(f) = Y$ holds according to the Axiom of Extension. We therefore obtain $f : X \twoheadrightarrow Y$ with the definition of a surjection, which completes the proof of the equivalence and thus the proof of the implication in (3.634). Since Y and f were arbitrary, we may now finally conclude that the proposed universal sentence is true. □

Proposition 3.193. *Any constant function with nonempty domain is a surjection, that is,*

$$\forall X, y\,(X \neq \emptyset \Rightarrow g_y : X \twoheadrightarrow \{y\}). \tag{3.638}$$

Proof. We take an arbitrary set $X \neq \emptyset$ and an arbitrary $\bar{y}$, so that $g_{\bar{y}} = X \times \{\bar{y}\}$ is a function from X to $\{\bar{y}\}$, by definition of a constant function. We now show that $g_{\bar{y}}$ satisfies

$$\forall y\,(y \in \{\bar{y}\} \Rightarrow \exists x\,(g_{\bar{y}}(x) = y)), \tag{3.639}$$

letting y be arbitrary and assuming $y \in \{\bar{y}\}$ to hold. Furthermore, as we assumed X to be nonempty, there exists an element in X, say $\bar{x}$. Thus, the conjunction $\bar{x} \in X \wedge y \in \{\bar{y}\}$ is true, which implies with the definition of the Cartesian product of two sets $(\bar{x}, y) \in X \times \{\bar{y}\}$ $[= g_{\bar{y}}]$, which we may write as $y = g_{\bar{y}}(\bar{x})$. Thus, there exists an x with $g_{\bar{y}}(x) = y$, which means that the existential sentence in (3.639) is true. As y is arbitrary, we may therefore conclude that the universal sentence (3.639) is true. Thus, $g_{\bar{y}}$ is a surjection according to the Surjection Criterion, and since X and $\bar{y}$ were arbitrary, we may therefore conclude that the proposed sentence holds. □

As singletons are nonempty, we then obtain immediately the following special case with Corollary 3.156.

Corollary 3.194. *The singleton formed by a pair (x, y) is a surjection from the singleton formed by x to the singleton formed by y, that is,*

$$\forall x, y\,(\{(x, y)\} : \{x\} \twoheadrightarrow \{y\}). \tag{3.640}$$

Note 3.24. The range of a function $\{(x, y)\}$ is identical with the singleton $\{y\}$.

Proposition 3.167 then yields the following equivalent representation of a surjection.

Corollary 3.195. *For any function $f : X \to Y$ and any element x of X, it is true that the restriction of f to the singleton $\{x\}$ is a surjection from $\{x\}$ to the singleton formed by the value of f at x, that is,*

$$\forall X, Y, f, x\,([f \in Y^X \wedge x \in X] \Rightarrow f \restriction \{x\} : \{x\} \twoheadrightarrow \{f(x)\}). \tag{3.641}$$

Note 3.25. The range of the restriction of a function $f : X \to Y$ to a singleton $\{x\}$ with $x \in X$ is given by the singleton $\{f(x)\}$, that is,

$$\forall X, Y, f, x\,([f \in Y^X \wedge x \in X] \Rightarrow \mathrm{ran}(f \restriction \{x\}) = \{f(x)\}). \tag{3.642}$$

Proposition 3.196. *The identity function on any set is a surjection, i.e.*

$$\forall X\,(\mathrm{id}_X : X \twoheadrightarrow X). \tag{3.643}$$

Proof. Letting X be an arbitrary set, we notice that id_X is by definition a function with codomain X. We now apply the Surjection Criterion to prove $\mathrm{id}_X : X \twoheadrightarrow X$, by verifying the equivalent

$$\forall y\,(y \in X \Rightarrow \exists x\,(\mathrm{id}_X(x) = y)). \tag{3.644}$$

For this purpose, we take an arbitrary y and assume $y \in X$ to be true. Since id_X is by definition a function with domain X, we see that $y \in X$ implies $\mathrm{id}_X(y) = y$ with the definition of an identity function. Thus, the existential sentence in (3.644) is true, and as y was arbitrary, we may therefore conclude that the universal sentence (3.644) holds. It then follows with the Surjection Criterion that id_X is a surjection from X to X. Because X was an arbitrary set, we may further conclude that the proposed universal sentence (3.643) is true. □

Proposition 3.197. *It is true for any nonempty sets X_1 and X_2 that the projection function from $X_1 \times X_2$ to X_1 is a surjection, i.e.*

$$\forall X_1, X_2\,([X_1 \neq \emptyset \wedge X_2 \neq \emptyset] \;\Rightarrow\; \pi_1 : X_1 \times X_2 \twoheadrightarrow X_1). \tag{3.645}$$

Proof. We take arbitrary sets X_1 and X_2, and we assume $X_1 \neq \emptyset$ as well as $X_2 \neq \emptyset$ to be true. To prove that the projection function $\pi_1 : X_1 \times X_2 \to X_1$ is a surjection with range X_1, we apply the Surjection Criterion and verify accordingly

$$\forall y\,(y \in X_1 \Rightarrow \exists z\,(\pi_1(z) = y)), \tag{3.646}$$

letting $y \in X_1$ be arbitrary (noting that X_1 is by assumption nonempty). Since we assumed X_2 to be also nonempty, there evidently exists an element in X_2, say $\bar{x}_2$. Then, the ordered pair $\bar{z} = (y, \bar{x}_2)$ is an element of $X_1 \times X_2$ by definition of the Cartesian product of two sets. Being thus in the domain of the projection function $\pi_1 : X_1 \times X_2 \to X_1$, we have that $\bar{z} = (y, \bar{x}_2)$ is associated with the value $\pi_1(\bar{z}) = \pi_1((y, \bar{x}_2)) = y$. This equation clearly demonstrates the truth of the existential sentence in (3.646), and as y was arbitrary, we may therefore conclude that the universal sentence (3.646) holds. Consequently, the projection function $\pi_1 : X_1 \times X_2 \to X_1$ is indeed a surjection (with range X_1), and since the sets X_1 and X_2 were initially arbitrary, we may now infer from this the truth of the proposition. □

Exercise 3.80. Show for any nonempty sets X_1 and X_2 that the projection function from $X_1 \times X_2$ to X_2 is a surjection, i.e.

$$\forall X_1, X_2\,([X_1 \neq \emptyset \wedge X_2 \neq \emptyset] \Rightarrow \pi_2 : X_1 \times X_2 \twoheadrightarrow X_2). \tag{3.647}$$

Exercise 3.81. Show for any x, any Y and any surjection f from the singleton formed by x to Y that Y is identical with the singleton formed by the function value at x, that is,

$$\forall x, Y, f\,(f : \{x\} \twoheadrightarrow Y \Rightarrow Y = \{f(x)\}). \tag{3.648}$$

(Hint: Apply Method 1.6 and use (2.18), (3.630), (3.108), (3.93), (2.169), and Notation 3.4.)

Proposition 3.198. *For any functions $f : X \to Y$ and $g : Y \to Z$ it is true that, if the composition of g and f is a surjection, then g is a surjection, that is,*

$$\forall X, Y, Z, f, g\,([f \in Y^X \wedge g \in Z^Y \wedge g \circ f : X \twoheadrightarrow Z] \Rightarrow g : Y \twoheadrightarrow Z). \tag{3.649}$$

Proof. We let X, Y, Z, f and g be arbitrary and prove the implication directly, assuming that f is a function from X to Y, that g is a function from Y to Z, and that the composition $g \circ f$, which is a function from X to Z due to Proposition 3.178 and the fact that the range of f is included in the codomain Y and thus in the domain of g, is a surjection. The latter assumption means that

$$\operatorname{ran}(g \circ f) = Z \tag{3.650}$$

holds. To show that the assumptions imply that $g : Y \to Z$ is a surjection from Y to Z, we prove $\operatorname{ran}(g) = Z$. For this purpose, we apply the Equality Criterion for sets and prove the equivalent

$$\forall y\,(y \in \operatorname{ran}(g) \Leftrightarrow y \in Z). \tag{3.651}$$

We let y be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $y \in \operatorname{ran}(g)$ holds. Since Z is the codomain of g, we have by definition that $\operatorname{ran}(g) \subseteq Z$ holds. With this and the definition of a subset, the assumption $y \in \operatorname{ran}(g)$ immediately implies the desired $y \in Z$. To prove the second part ('$\Leftarrow$') of the equivalence directly, we now assume $y \in Z$ to be true. This implies with the equation (3.650) that $y \in \operatorname{ran}(g \circ f)$ is true, so that there exists by definition of a range an element, say $\bar{x}$, such that $(\bar{x}, y) \in g \circ f$. This means $g(f(\bar{x})) = y$ with Notation 3.6 and then also $(f(\bar{x}), y) \in g$ with Notation 3.4. Consequently, $y \in \operatorname{ran}(g)$ holds (by definition of a range), which completes the proof of the equivalence. As y

is arbitrary, we therefore conclude that (3.651) is true, which proves the equation $\mathrm{ran}(g) = Z$. Thus, $g : Y \to Z$ is a surjection by definition. Since X, Y, Z, f and g were also arbitrary, it follows that the proposed universal sentence holds, as claimed. □

Theorem 3.199 (Surjectivity of the composition of two surjections). *The composition of a surjection g from a set Y to a set Z and a surjection f from a set X to Y is itself a surjection from X to Z, that is,*

$$\forall X, Y, Z, f, g\,([f : X \twoheadrightarrow Y \,\wedge\, g : Y \twoheadrightarrow Z] \Rightarrow g \circ f : X \twoheadrightarrow Z). \tag{3.652}$$

Proof. We let X, Y and Z be arbitrary sets, f an arbitrary surjection from X to Y, and g an arbitrary injection from Y to Z. Then, $g \circ f$ is a function from X to Z due to (3.604). To prove that $g \circ f$ is a surjection, we demonstrate the truth of $\mathrm{ran}(g \circ f) = Z$ according to (3.630). For this purpose, we first verify $Z \subseteq \mathrm{ran}(g \circ f)$, i.e. (applying the definition of a subset)

$$\forall z\,(z \in Z \Rightarrow z \in \mathrm{ran}(g \circ f)). \tag{3.653}$$

To do this, we take an arbitrary element $\bar{z}$ from Z and show that $\bar{z} \in \mathrm{ran}(g \circ f)$ holds. Now, as g is by assumption a surjection from Y to Z, it is true that $\mathrm{ran}(g) = Z$. Therefore, $\bar{z} \in Z$ implies $\bar{z} \in \mathrm{ran}(g)$, so that there exists by definition of a range an element, say $\bar{y}$, with $(\bar{y}, \bar{z}) \in g$. This in turn implies $\bar{y} \in \mathrm{dom}(g)$ $[= Y]$ by definition of a domain, so that $\bar{y} \in Y$ is true. Moreover, since f was assumed to be a surjection from X to Y, we have that $\mathrm{ran}(f) = Y$. Consequently, $\bar{y} \in Y$ gives $\bar{y} \in \mathrm{ran}(f)$, which implies (again by definition of a range) the existence of an element, say $\bar{x}$, such that $(\bar{x}, \bar{y}) \in f$. Then, the ordered pair $(\bar{x}, \bar{z})$ is specified, where $(\bar{x}, \bar{y}) \in f$ and $(\bar{y}, \bar{z}) \in g$ hold, so that the existential sentence

$$\exists x, y, z\,((x, y) \in f \,\wedge\, (y, z) \in g \,\wedge\, (x, z) = (\bar{x}, \bar{z})) \tag{3.654}$$

is true. This gives $(\bar{x}, \bar{z}) \in g \circ f$ with the definition of a composition. Applying now the definition of a range again, we obtain the desired $\bar{z} \in \mathrm{ran}(g \circ f)$. As $\bar{z}$ was arbitrary, it then follows from this that the universal sentence (3.653) is true, which means (by definition of a subset) that $Z \subseteq \mathrm{ran}(g \circ f)$ holds. Since $g \circ f$ is a function with codomain Z, as mentioned earlier, the inclusion $\mathrm{ran}(g \circ f) \subseteq Z$ is also true, so that the Axiom of Extension gives the equality $\mathrm{ran}(g \circ f) = Z$. Thus, the composition $g \circ f : X \to Z$ is a surjection, by definition. Since X, Y, Z, f and g were arbitrary, we may therefore finally conclude that the theorem is true. □

Proposition 3.200. *If the composition of two functions f and g is the identity function (on the domain of f), then f is an injection and g a surjection, that is,*

$$\forall X, Y, f, g\,([f : X \to Y \,\wedge\, g : Y \to X \,\wedge\, g \circ f = \mathrm{id}_X] \\ \Rightarrow [f : X \hookrightarrow Y \,\wedge\, g : Y \twoheadrightarrow X]). \tag{3.655}$$

Proof. We let $f : X \to Y$ and $g : Y \to X$ be arbitrary functions such that $g \circ f = \mathrm{id}_X$ is true. To show that f is an injection, we prove

$$\forall x, x'\,([x, x' \in X \,\wedge\, f(x) = f(x')] \Rightarrow x = x'). \tag{3.656}$$

For this purpose, we take two arbitrary elements x and x' from X such that $f(x) = f(x')$ holds. Then, we obtain

$$x = \mathrm{id}_X(x) = (g \circ f)(x) = g(f(x)) = g(f(x')) = (g \circ f)(x') = \mathrm{id}_X(x') = x'$$

by applying the definition of the identity function on X, substitution based on the initial assumption $g \circ f = \mathrm{id}_X$, Notation 3.6, then substitution based on the assumption$f(x) = f(x')$, again Notation 3.6, again the initial assumption $g \circ f = \mathrm{id}_X$, and finally again the definition of the identity function on X. These equations yield $x = x'$, which proves the implication in (3.656), and since x and x' are arbitrary, we may therefore conclude that (3.656) is true. Thus, the function $f : X \to Y$ is an injection by definition, i.e. $f : X \hookrightarrow Y$.

To show that $g : Y \to X$ is a surjection, we apply the Surjection Criterion and verify accordingly

$$\forall x\,(x \in X \Rightarrow \exists y\,(g(y) = x)). \tag{3.657}$$

We let x be arbitrary and prove the implication directly, assuming $x \in X$ to hold. Since f is a function from X to Y, we see in light of the Function Criterion that $x \in X$ implies the existence of the unique value $\bar{y}$ satisfying $\bar{y} \in X$ and $(x, \bar{y}) \in f(x)$. Observing that we may write the latter as $f(x) = \bar{y}$ (since f is a function) and recalling the truth of the equations

$$x = \mathrm{id}_X(x) = (g \circ f)(x) = g(f(x)),$$

we therefore obtain after substitution $g(\bar{y}) = x$. We thus showed that there exists an y in Y with $g(y) = x$, which completes the proof of the implication in (3.657). Then, as x is arbitrary, the universal sentence (3.657) follows to be true, so that $g : Y \to X$ is indeed a surjection (according to the Surjection Criterion), i.e. $g : Y \twoheadrightarrow X$.

Since X, Y, f and g were arbitrary, we may therefore conclude that the proposition holds, as claimed. □

We now combine the concepts of injectivity and surjectivity.

Definition 3.49 (Bijection, one-to-one correspondence). We say that a function $f : X \to Y$ is a *bijection* or a *one-to-one correspondence*, symbolically

$$f : X \rightleftarrows Y, \tag{3.658}$$

if, and only if,

1. f is a one-to-one function (from X to Y), that is,

$$f : X \hookrightarrow Y, \tag{3.659}$$

   and

2. f is a surjection (from X to Y), that is,

$$f : X \twoheadrightarrow Y, \tag{3.660}$$

The following trivial example for a bijection results directly from Exercise 3.76 and Exercise 3.79.

Corollary 3.201. *The function $\emptyset : \emptyset \to \emptyset$ is a bijection, i.e.*

$$\emptyset : \emptyset \rightleftarrows \emptyset, \tag{3.661}$$

and this function is the only bijection from $\emptyset$ to $\emptyset$.

Similarly, the Corollaries 3.184 and 3.194 give the bijectivity of functions with a single value.

Corollary 3.202. *The singleton formed by a pair (x, y) is a bijection from the singleton formed by x to the singleton formed by y, that is,*

$$\forall x, y\, (\{(x, y)\} : \{x\} \rightleftarrows \{y\}). \tag{3.662}$$

Moreover, the conjunction of Corollary 3.189 and Proposition 3.196 yields the following useful one-to-one correspondence.

Corollary 3.203. *The identity function on any set is a bijection, that is,*

$$\forall X\, (\mathrm{id}_X : X \rightleftarrows X). \tag{3.663}$$

Corollary 3.204. *For any injection f from a set X to a set Y it is true that f is a bijection from X to the range of f, that is,*

$$\forall X, Y, f\, (f : X \hookrightarrow Y \;\Rightarrow\; f : X \rightleftarrows \mathrm{ran}(f)) \tag{3.664}$$

Proof. We let X, Y and f be arbitrary sets and assume that $f : X \hookrightarrow Y$. Therefore, $f : X \hookrightarrow \mathrm{ran}(f)$ follows to be true with (3.622). Since $f : X \twoheadrightarrow \mathrm{ran}(f)$ also holds by definition of a surjection, we obtain the desired result $f : X \rightleftarrows \mathrm{ran}(f)$ with the definition of a bijection. As X, Y and f are arbitrary, the proposed sentence follows then to be true. □

Proposition 3.205. *Removing any ordered pair from a bijection yields again a bijection, that is,*

$$\forall X, Y, f, x, y\,([f : X \rightleftarrows Y \wedge (x, y) \in f] \Rightarrow f \setminus \{(x, y)\} : X \setminus \{x\} \rightleftarrows Y \setminus \{y\}). \tag{3.665}$$

Proof. We let X and Y be arbitrary sets, f an arbitrary bijection from X to Y, and (x, y) an arbitrary ordered pair in f. The latter may be written as $y = f(x)$ and furthermore implies that $x \in X$ and $y \in \mathrm{ran}(f)$ hold by definitions of a domain and of a range, respectively. As a bijection, f is by definition both an injection (i.e., $f : X \hookrightarrow Y$) and a surjection (i.e., $f : X \twoheadrightarrow Y$). As $X \setminus \{x\}$ is a subset of X due to (2.125), it follows with Proposition 3.187 from $f : X \hookrightarrow Y$ that $f \restriction X \setminus \{x\}$ is an injection from $X \setminus \{x\}$ to Y. This restriction is identical with $f \setminus \{(x, y)\}$ because of Proposition 3.168. Now, the fact that $f : X \twoheadrightarrow Y$ also holds implies $Y = \mathrm{ran}(f)$ by definition of a surjection. We now verify that the range of (the injection) $f \setminus \{(x, y)\}$ equals $Y \setminus \{y\}$ (which will prove that this function is a bijection from $X \setminus \{x\}$ to $Y \setminus \{y\}$). We demonstrate the truth of that equality by proving the equivalent (applying (2.18))

$$\forall z\,(z \in \mathrm{ran}(f \setminus \{(x, y)\}) \Leftrightarrow z \in Y \setminus \{y\}). \tag{3.666}$$

Letting z be arbitrary, we prove the first part ('$\Rightarrow$') of the stated equivalence directly, assuming $z \in \mathrm{ran}(f \setminus \{(x, y)\})$. By definition of a range, there exists an element, say $\bar{x}$, such that $(\bar{x}, z) \in f \setminus \{(x, y)\}$. This implies by definition of a domain that $\bar{x} \in \mathrm{dom}(f \setminus \{(x, y)\})$ and therefore $\bar{x} \in \mathrm{dom}(f \restriction X \setminus \{x\})$, so that $\bar{x} \in X \setminus \{x\}$. Consequently, $\bar{x} \in X$ and $\bar{x} \notin \{x\}$ are both true by definition of a set difference. The latter implies $\bar{x} \neq x$ with (2.169); together with the previously obtained $\bar{x}, x \in X$, the preceding inequality implies $f(\bar{x}) \neq f(x)$ with the Injection Criterion, since f is an injection. As $(\bar{x}, z) \in f \setminus \{(x, y)\}$ also implies in particular $(\bar{x}, z) \in f$ (with the definition of a set difference), we see that $f(\bar{x}) = z$ holds; together with the initially assumed $f(x) = y$, the inequality $f(\bar{x}) \neq f(x)$ gives $z \neq y$, and therefore $z \notin \{y\}$ (again with (2.169)). As the range of the injection $f \setminus \{(x, y)\}$ is included in its codomain Y, it also follows from $z \in \mathrm{ran}(f \setminus \{(x, y)\})$ that $z \in Y$ is true (applying the definition of a subset). Thus, the conjunction $z \in Y \wedge z \notin \{y\}$ holds, which means $z \in Y \setminus \{y\}$ (by definition of a set difference), which proves the first part of the equivalence in (3.666).

We now prove the second part ('$\Leftarrow$') directly, assuming now that $z \in Y \setminus \{y\}$ holds. Clearly, this implies in particular $z \in Y$, (by definition of a set difference) so that y is an element of the range Y of the bijection $f : X \rightleftarrows Y$. Thus, by definition of a binary relation, there exists an element, say $\bar{x}$, with $(\bar{x}, z) \in f$. Then, $\bar{x} \in \mathrm{dom}(f)$ holds by definition of a domain, so that $\bar{x} \in X$. Clearly, the assumption $z \in Y \setminus \{y\}$ also implies $z \notin \{y\}$ and therefore $z \neq y$ with (2.169). Then, the fact that $z = f(\bar{x})$ and $y = f(x)$ are both true implies with the preceding inequality that $f(\bar{x}) \neq f(x)$, with the consequence that $\bar{x} \neq x$ holds due to (3.525). This further implies $\bar{x} \notin \{x\}$ with (2.169), so that the conjunction $\bar{x} \in X \wedge \bar{x} \notin \{x\}$ is true, which clearly means that $\bar{x} \in X \setminus \{x\}$. Thus, $\bar{x}$ is an element of the domain $X \setminus \{x\}$ of the injection $f \restriction X \setminus \{x\}$, thus of $\mathrm{ran}(f \setminus \{(x, y)\})$, completing the proof of the second part of the equivalence. As z is arbitrary, we therefore conclude that (3.666) is true, so that the range of the injection $f \setminus \{(x, y)\}$ from $X \setminus \{x\}$ to Y is indeed identical with $Y \setminus \{y\}$. This shows that this injection is also a surjection, and therefore a bijection. Since X, Y, f, x and y were all arbitrary, we therefore conclude that (3.665) holds. □

Proposition 3.206. *Adjoining to a bijection f an ordered pair whose first coordinate is not in the domain and whose second coordinate is not in the range of f yields again a bijection, that is,*

$$\forall X, Y, f\,(f : X \rightleftarrows Y \Rightarrow \forall x, y\,([x \notin X \;\wedge\; y \notin Y] \\ \Rightarrow f \cup \{(x, y)\} : X \cup \{x\} \rightleftarrows Y \cup \{y\})). \tag{3.667}$$

Proof. Letting X, Y and f be arbitrary sets and assuming $f : X \rightleftarrows Y$ to be true, we also take arbitrary $\bar{x}$ and $\bar{y}$ and assume furthermore that $\bar{x} \notin X$ and $\bar{y} \notin Y$ hold. Then, $F = f \cup \{(\bar{x}, \bar{y})\}$ is a function with domain $X \cup \{\bar{x}\}$ because of Proposition 3.177, and $g = \{(\bar{x}, \bar{y})\}$ is a surjection with domain $\{\bar{x}\}$ and range $\{\bar{y}\}$ due to Corollary 3.194. We now prove that F is a surjection by applying Corollary 3.191, i.e. by verifying

$$\forall y\,(y \in Y \cup \{\bar{y}\} \Leftrightarrow \exists x\,(F(x) = y)). \tag{3.668}$$

We take an arbitrary y and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in Y \cup \{\bar{y}\}$ to be true. Consequently, the disjunction $y \in Y \,\vee\, y \in \{\bar{y}\}$ holds by definition of the union of two sets. On the one hand, if $y \in Y$ is true, then it follows with the surjectivity of the assumed bijection $f : X \rightleftarrows Y$ in connection with the Surjection Criterion that there exists an element, say $\bar{\bar{x}}$, such that $f(\bar{\bar{x}}) = y$ holds, which we may also write as $(\bar{\bar{x}}, y) \in f$. Since $F = f \cup \{(\bar{x}, \bar{y})\}$ implies $f \subseteq F$ with Proposition 2.67, it follows that $(\bar{\bar{x}}, y) \in F$ is true, which we may also write as $F(\bar{\bar{x}}) = y$. This proves the existential sentence in (3.668) in case of $y \in Y$.

On the other hand, if $y \in \{\bar{y}\}$ is true, then we obtain $y = \bar{y}$ with (2.169). Since $F = f \cup \{(\bar{x}, \bar{y})\}$ implies also $\{(\bar{x}, \bar{y})\} \subseteq F$, the evident fact $(\bar{x}, \bar{y}) \in \{(\bar{x}, \bar{y})\}$ gives $(\bar{x}, \bar{y}) \in F$ with the definition of a subset. Then, substitution based on the previously established equation $y = \bar{y}$ yields $(\bar{x}, y) \in F$, which we may also write as $F(\bar{x}) = y$. Thus, the existential sentence in (3.668) holds also in case of $y \in \{\bar{y}\}$.

To prove the second part ('$\Leftarrow$') of the equivalence in (3.668), we now assume that there exists an element, say $\bar{\bar{x}}$, satisfying $F(\bar{\bar{x}}) = y$, i.e. $(\bar{\bar{x}}, y) \in F$. Therefore, the disjunction $(\bar{\bar{x}}, y) \in f \,\vee\, (\bar{\bar{x}}, y) \in \{(\bar{x}, \bar{y})\}$ holds by definition of the union of two sets in connection with the definition of F. On the one hand, if $(\bar{\bar{x}}, y) \in f$ is true, then we obtain $y \in \mathrm{ran}(f)$ $[= Y]$ with the definition of a range and the surjectivity of f. Then, the disjunction $y \in Y \vee y \in \{\bar{y}\}$ is also true, which gives the desired consequent $y \in Y \cup \{\bar{y}\}$ (using again the definition of the union of two sets).

On the other hand, if $(\bar{\bar{x}}, y) \in \{(\bar{x}, \bar{y})\}$ holds, then we obtain $y \in \mathrm{ran}(g)$ $[= \{\bar{y}\}]$ with the definition of a range and the surjectivity of $g = \{(\bar{x}, \bar{y})\}$. Then, the disjunction $y \in Y \,\vee\, y \in \{\bar{y}\}$ is again true, with the already established consequence that $y \in Y \cup \{\bar{y}\}$ holds, as desired.

Thus, the proof of the equivalence is complete. As y is arbitrary, we may therefore conclude that the universal sentence (3.668) is true, which then implies $F : X \cup \{\bar{x}\} \twoheadrightarrow Y \cup \{\bar{y}\}$ with Corollary 3.191.

We now prove that F is also an injection by applying the Injection Criterion, i.e. by verifying

$$\forall x, x' \left([x, x' \in X \cup \{\bar{x}\} \,\wedge\, x \neq x'] \Rightarrow F(x) \neq F(x')\right). \tag{3.669}$$

We let x and x' be arbitrary and assume that both $x, x' \in X \cup \{\bar{x}\}$ and $x \neq x'$ are true. Introducing the denotations $y = F(x)$ and $y' = F(x')$, we may also write $(x, y) \in F$ and $(x', y') \in F$. Recalling $F = f \cup \{(\bar{x}, \bar{y})\}$, it now follows from $(x, y) \in F$ with the definition of the union of two sets that the disjunction

$$(x, y) \in f \,\vee\, (x, y) \in \{(\bar{x}, \bar{y})\} \tag{3.670}$$

is true. We assume first that $(x, y) \in f$ holds, i.e. $y = f(x)$, which gives $x \in X$ and $y \in Y$ with (3.517). Now, the previously obtained $(x', y') \in F$ yields the true disjunction

$$(x', y') \in f \,\vee\, (x', y') \in \{(\bar{x}, \bar{y})\}, \tag{3.671}$$

applying again the definition of the union of two sets. On the one hand, if the first part $(x', y') \in f$ of this disjunction holds, i.e. $y' = f(x')$, then we obtain $x' \in X$ and $y' \in Y$, using (3.517) again. Thus, the conjunction $x, x' \in X \wedge x \neq x'$ is true, which in turn implies $f(x) \neq f(x')$ with the Injection Criterion (recalling that we assumed f to be an injection with domain X). Now, substitution yields $y \neq y'$ and then $F(x) \neq F(x')$, so that the desired consequent in (3.669) holds in case of $(x, y) \in f$ and $(x', y') \in f$.

On the other hand, if the second part $(x', y') \in \{(\bar{x}, \bar{y})\}$ of the disjunction (3.671) is true (alongside $(x, y) \in f$), then we obtain $(x', y') = (\bar{x}, \bar{y})$ with (2.169) and moreover $x' = \bar{x}$ as well as $y' = \bar{y}$ with the Equality Criterion for ordered pairs. Consequently, the assumed $\bar{y} \notin Y$ yields $y' \notin Y$, so that the conjunction $y \in Y \wedge y' \notin Y$ holds, which in turn implies $y \neq y'$ with (2.4). Therefore, $F(x) \neq F(x')$ holds also in case of $(x, y) \in f$ and $(x', y') \in \{(\bar{x}, \bar{y})\}$.

We now assume that the second part $(x, y) \in \{(\bar{x}, \bar{y})\}$ of the disjunction (3.670) holds, so that $(x, y) = (\bar{x}, \bar{y})$ follows to be true with (2.169), which equation gives then $x = \bar{x}$ as well as $y = \bar{y}$ with the Equality Criterion for ordered pairs. Thus, the assumed $\bar{y} \notin Y$ gives now $y \notin Y$. Let us now observe that the disjunction (3.671) is again true. We now prove by contradiction that $(x', y') \in \{(\bar{x}, \bar{y})\}$ is false. Indeed, assuming $(x', y') \in \{(\bar{x}, \bar{y})\}$ to be true, we evidently obtain $(x', y') = (\bar{x}, \bar{y})$ and then $x' = \bar{x}$ (alongside $y' = \bar{y}$), so that substitution based on the previously established $x = \bar{x}$ yields $x = x'$, in contradiction to the initially assumed $x \neq x'$. Therefore, the first part $(x', y') \in f$ of the disjunction (3.671) is true, which we may write as $y' = f(x')$. Then, we obtain as before $x' \in X$ and $y' \in Y$, so that the conjunction $y' \in Y \wedge y \notin Y$ is true. This further implies $y' \neq y$ with (2.4), and therefore $F(x) \neq F(x')$ holds also in case of $(x, y) \in \{(\bar{x}, \bar{y})\}$.

This completes the proof of the implication in (3.669), and since x, x' are arbitrary, we may infer from this the truth of the universal sentence (3.669), and therefore the injectivity of F. Consequently, the injective surjection $F : X \cup \{\bar{x}\} \twoheadrightarrow Y \cup \{\bar{x}\}$ is a bijection, by definition. Since $\bar{x}$ and $\bar{y}$ are arbitrary, we may therefore conclude that the universal sentence in (3.667) with respect to x and y is true. Moreover, as X, Y and f were also arbitrary, we may finally conclude that the proposition holds, as claimed. □

Theorem 3.207 (Bijectivity of the composition of two bijections). *It is true that the composition of a bijection g from a set Y to a set Z and a bijection f from a set X to Y is itself a bijection from X to Z, that is,*

$$\forall X, Y, Z, f, g\,([f : X \rightleftarrows Y \wedge g : Y \rightleftarrows Z] \Rightarrow g \circ f : X \rightleftarrows Z). \tag{3.672}$$

Proof. Letting X, Y and Z be arbitrary sets, f an arbitrary bijection from X to Y and g an arbitrary bijection from Y to Z, it follows with the definition of a bijection on the one hand that f is both an injection and a surjection from X to Y; on the other hand, g is then both an injection and a surjection from Y to Z. Therefore, the conjunctions

$$f : X \hookrightarrow Y \wedge g : Y \hookrightarrow Z$$
$$f : X \twoheadrightarrow Y \wedge g : Y \twoheadrightarrow Z$$

are true. Here, the former implies $g \circ f : X \hookrightarrow Z$ with (3.627) and the latter $g \circ f : X \twoheadrightarrow Z$ with (3.652). These findings show that $g \circ f$ is both an injection and a surjection from X to Z, so that (by definition of a bijection) $g \circ f : X \rightleftarrows Z$ holds. This proves the implication in (3.672), and since X, Y, Z, f and g were arbitrary, the theorem follows then to be true. □

3.4.4. Inverses of functions

Lemma 3.208. *The inverse of a one-to-one correspondence $f : X \rightleftarrows Y$ is a function from Y to X, that is,*

$$\forall X, Y, f\,(f : X \leftrightarrows Y \;\Rightarrow f^{-1} : Y \to X). \tag{3.673}$$

Proof. We let X, Y and f be arbitrary sets such that f is a one-to-one correspondence from X to Y; thus, f is in particular an onto function with $\mathrm{dom}(f) = X$ and $\mathrm{ran}(f) = Y$. It then follows with Corollary 3.42 that $f^{-1} \subseteq Y \times X$ holds. We may therefore apply the Function Criterion to prove $f^{-1} : Y \to X$, by verifying

$$\forall y\,(y \in Y \Rightarrow \exists! x\,(x \in X \;\wedge\; (y, x) \in f^{-1})). \tag{3.674}$$

For this purpose, we let $\bar{y} \in Y$ be arbitrary and establish first the existential part of the uniquely existential sentence. Because of $\mathrm{ran}(f) = Y$, we see in light of the definition of a range that $\bar{y} \in Y$ implies that there exists an element, say $\bar{x}$, such that $(\bar{x}, \bar{y}) \in f$ holds. Therefore, $\bar{x} \in X$ $[= \mathrm{dom}(f)]$ follows to be true by definition of a domain. Thus, the conjunction $\bar{y} \in Y \wedge \bar{x} \in X$ holds, which in turn implies $(\bar{y}, \bar{x}) \in Y \times X$ with the definition of the Cartesian product of two sets. Moreover, we see that there are elements x and y satisfying $(x, y) \in f$ and $(y, x) = (\bar{y}, \bar{x})$, which existential sentence then implies $(\bar{y}, \bar{x}) \in f^{-1}$ with the definition of the inverse of a binary relation. Thus, $\bar{x} \in X$ and $(\bar{y}, \bar{x}) \in f^{-1}$ are both true, proving the existential part in (3.674). To establish the uniqueness part, we verify

$$\forall x, x'\,([x \in X \wedge (\bar{y}, x) \in f^{-1} \wedge x' \in X \wedge (\bar{y}, x') \in f^{-1}] \Rightarrow x = x'). \tag{3.675}$$

We let $\bar{x}$ and $\bar{x}'$ be arbitrary elements of X satisfying $(\bar{y}, \bar{x}) \in f^{-1}$ and $(\bar{y}, \bar{x}') \in f^{-1}$. On the one hand, $(\bar{y}, \bar{x}) \in f^{-1}$ implies with the definition of the inverse of a binary relation that there are elements, say $\bar{\bar{x}}$ and $\bar{\bar{y}}$, such that $(\bar{\bar{x}}, \bar{\bar{y}}) \in f$ and $(\bar{\bar{y}}, \bar{\bar{x}}) = (\bar{y}, \bar{x})$; the latter equation further implies $\bar{\bar{y}} = \bar{y}$ and $\bar{\bar{x}} = \bar{x}$ with the Equality Criterion for ordered pairs, and therefore $(\bar{x}, \bar{y}) \in f$.

On the other hand, $(\bar{y}, \bar{x}') \in f^{-1}$ implies (again by definition of the inverse of a binary relation) that there are elements, say $\bar{\bar{x}}'$ and $\bar{\bar{y}}'$, with $(\bar{\bar{x}}', \bar{\bar{y}}') \in f$ and $(\bar{\bar{y}}', \bar{\bar{x}}') = (\bar{y}, \bar{x}')$; this equation now yields $\bar{\bar{y}}' = \bar{y}$ and $\bar{\bar{x}}' = \bar{x}'$ (using again the Equality Criterion for ordered pairs), so that $(\bar{x}', \bar{y}) \in f$.

Thus, $(\bar{x}, \bar{y}) \in f$ and $(\bar{x}', \bar{y}) \in f$ are both true, which we may write in function notation as $\bar{y} = f(\bar{x})$ and $\bar{y} = f(\bar{x}')$. Clearly, we may combine these equations via substitution to obtain $f(\bar{x}) = f(\bar{x}')$, which then implies $\bar{x} = \bar{x}'$ with the initial assumption that f is an injection. As $\bar{x}$ and $\bar{x}'$ are arbitrary, we therefore conclude that the universal sentence (3.675) is true, which then completes the proof of the uniqueness part, and thus the proof of the uniquely existential sentence in (3.674). Since $\bar{y}$ was also arbitrary, we may now further conclude that (3.674) holds, which then implies the desired $f^{-1} : Y \to X$ with the Function Criterion. Because X, Y and f were arbitrary, we finally conclude that the lemma is indeed true. □

Exercise 3.82. Show that the inverse of a one-to-one function $f : X \hookrightarrow Y$ is a function from the range to the domain of f, that is,

$$\forall X, Y, f\, (f : X \hookrightarrow Y \;\Rightarrow f^{-1} : \operatorname{ran}(f) \to X). \tag{3.676}$$

(Hint: Proceed in analogy to the proof of Lemma 3.208.)

Proposition 3.209. *For any injection f from a set X to a set Y it is true that an element x is the value of the inverse f^{-1} at an element y iff y is the value of f at x, that is,*

$$\forall X, Y, f, x, y\, (f : X \hookrightarrow Y \;\Rightarrow [x = f^{-1}(y) \Leftrightarrow y = f(x)]). \tag{3.677}$$

Proof. We let X, Y, f, x and y be arbitrary and assume that f is an injection from X to Y, so that the inverse f^{-1} of f is a function from $\operatorname{ran}(f)$ to X according to Exercise 3.82.

To prove the first part ('⇒') of the equivalence in (3.677), we assume $x = f^{-1}(y)$, which equation we may also write as $(y, x) \in f^{-1}$. This implies with Proposition 3.43 $(x, y) \in f$, which we may also write as $y = f(x)$. Thus, the first part of the equivalence in (3.678) holds.

Regarding the second part ('⇐'), we now assume $y = f(x)$ to be true, so that $(x, y) \in f$ holds. This implies $(y, x) \in f^{-1}$ with Proposition 3.43, so that $x = f^{-1}(y)$ holds, as desired.

This completes the proof of the equivalence and thus the proof of the implication in (3.678). As X, Y, f, x and y were initially arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Definition 3.50 (Inverse function). For any one-to-one correspondence f we call f^{-1} the *inverse function* of f.

Theorem 3.210 (Characterization of the function values of an inverse function). *For any bijection f from a set X to a set Y it is true that an element x is the value of the inverse function f^{-1} at an element y iff y is the value of f at x, i.e.*

$$\forall X, Y, f, x, y\,(f : X \rightleftarrows Y \;\Rightarrow [x = f^{-1}(y) \Leftrightarrow y = f(x)]). \tag{3.678}$$

Exercise 3.83. Prove Theorem 3.210.

(Hint: Proceed in analogy to the proof of Proposition 3.209.)

Lemma 3.211. *For any bijection $f : X \rightleftarrows Y$ it is true that*

a) the composition $f^{-1} \circ f$ is the identity function on X, that is,

$$\forall X, Y, f\,(f : X \rightleftarrows Y \;\Rightarrow f^{-1} \circ f = \mathrm{id}_X). \tag{3.679}$$

b) the composition $f \circ f^{-1}$ is the identity function on Y, that is,

$$\forall X, Y, f\,(f : X \rightleftarrows Y \;\Rightarrow f \circ f^{-1} = \mathrm{id}_Y). \tag{3.680}$$

Proof. Concerning a), letting $f : X \rightleftarrows Y$ be an arbitrary bijection, we first observe that (3.673) gives the inverse function $f^{-1} : Y \to X$. Then, (3.604) yields the composition $f^{-1} \circ f : X \to X$. Next, we apply the Function Criterion to verify $f^{-1} \circ f = \mathrm{id}_X$, by proving

$$\forall x\,(x \in X \Rightarrow (f^{-1} \circ f)(x) = \mathrm{id}_X(x)) \tag{3.681}$$

We let $\bar{x}$ be an arbitrary element of X, so that $\mathrm{id}_X(\bar{x}) = \bar{x}$ holds by definition of an identity function. Furthermore, there exists in view of the Function Criterion the unique value $\bar{y} \in Y$ with $(\bar{x}, \bar{y}) \in f$, which we may write in function notation as $\bar{y} = f(\bar{x})$. These findings show that there exist x and y such that $(x, y) \in f$ and $(y, x) = (\bar{y}, \bar{x})$ hold, which existential sentence implies $(\bar{y}, \bar{x}) \in f^{-1}$ by definition of the inverse of a binary relation, which we may also write as $\bar{x} = f^{-1}(\bar{y})$ (recalling that f^{-1} is a function) and then also as $\bar{x} = f^{-1}(f(\bar{x}))$, using the previously established equation $\bar{y} = f(\bar{x})$. Applying now Notation 3.6, this gives

$$[\mathrm{id}_X(\bar{x}) =] \quad \bar{x} = (f^{-1} \circ f)(\bar{x}),$$

and therefore $(f^{-1} \circ f)(\bar{x}) = \mathrm{id}_X(\bar{x})$. Since $\bar{x}$ is arbitrary, we may therefore conclude that the universal sentence (3.681) is true, so that the proof of $f^{-1} \circ f = \mathrm{id}_X$ is complete. Because X, Y and f were arbitrary, Part a) of the lemma follows then to be true. □

Exercise 3.84. Prove Part b) of Lemma 3.211.

Exercise 3.85. Show that Part a) of Lemma 3.211 holds also for any injection $f : X \hookrightarrow Y$, that is,

$$\forall X, Y, f\,(f : X \hookrightarrow Y \;\Rightarrow f^{-1} \circ f = \mathrm{id}_X). \tag{3.682}$$

(Hint: Use (3.676) and proceed similarly as in the proof of Lemma 3.211a).)

Theorem 3.212 (Bijectivity of inverse functions). *The inverse function of a bijection is also a bijection, that is,*

$$\forall X, Y, f\,(f : X \rightleftarrows Y \;\Rightarrow\; f^{-1} : Y \rightleftarrows X). \tag{3.683}$$

Proof. We let $f : X \rightleftarrows Y$ be an arbitrary bijection. Then, Lemma 3.211 yields the true conjunction

$$f^{-1} \circ f = \mathrm{id}_X \;\wedge\; f \circ f^{-1} = \mathrm{id}_Y.$$

Let us now observe in light of Lemma 3.208 that f^{-1} is a function from Y to X. Then, the first part $f^{-1} \circ f = \mathrm{id}_X$ of the preceding conjunction implies – together with $f : X \rightleftarrows Y$ and $f^{-1} : Y \rightleftarrows X$ – that f^{-1} is a surjection from Y to X, according to Proposition 3.200. Similarly, the second part $f \circ f^{-1} = \mathrm{id}_Y$ implies that f^{-1} is an injection from Y to X, so that f^{-1} is by definition a bijection from Y to X. Since X, Y and f were arbitrary, we therefore conclude that the theorem holds. □

The Bijectivity of inverse functions leads us to define the following type of function.

Definition 3.51 (Invertible transformation). We call any bijection

$$t : X \rightleftarrows X \tag{3.684}$$

on any set X an *invertible transformation*.

Note 3.26. The identity function id_X on any set X is an invertible transformations, as shown by (3.663).

Note 3.27. We may evidently apply the Axiom of Specification and the Equality Criterion for sets to prove that there exists a unique set $\mathcal{T}(X)$ consisting precisely of all bijective transformations on X, in the sense that

$$\forall f\,(f \in \mathcal{T}(X) \Leftrightarrow [f \in X^X \;\wedge\; f : X \rightleftarrows X]). \tag{3.685}$$

Since $f \in \mathcal{T}(X)$ implies $f \in X^X$ for every f, we find that the set $\mathcal{T}(X)$ is a subset of the set X^X of transformations on X. Given any subset $T(X) \subseteq \mathcal{T}(X)$, we also find that $T(X)$ is a subset of X^X due to (2.13).

Definition 3.52 (Set of invertible transformations). For any set X, we call

$$\mathcal{T}(X) \tag{3.686}$$

the *set of invertible transformations* on X. In addition, we call any subset

$$T(X) \tag{3.687}$$

of $\mathcal{T}(X)$ $\underline{\text{a}}$ set of invertible transformations.

Note 3.28. As an extension of Note 3.27, we may, for any set X, also establish the unique existence of a set $\mathcal{T}_{fi}(X)$ consisting of all the invertible transformations on X under which f is invariant, in the sense that

$$\forall t\,(t \in \mathcal{T}_{fi}(X) \Leftrightarrow [t \in \mathcal{T}(X) \,\wedge\, f \circ t = f]). \tag{3.688}$$

Since $t \in \mathcal{T}_{fi}(X)$ implies $t \in \mathcal{T}(X)$ and then $t \in X^X$ for any f, we see that $\mathcal{T}_{fi}(X)$ is a subset both of the set $\mathcal{T}(X)$ of invertible transformations and of the set X^X of transformations on X. Given any subset $T_{fi}(X) \subseteq \mathcal{T}_{fi}(X)$, we also find the inclusions $T_{fi}(X) \subseteq \mathcal{T}(X)$ and $T_{fi}(X) \subseteq X^X$ by virtue of (2.13).

Definition 3.53 (Set of invertible transformations under which a function is invariant). For any function $f : X \to Y$, we call

$$\mathcal{T}_{fi}(X) \tag{3.689}$$

the *set of invertible transformations* (on X) *under which f is invariant.* Furthermore, we call any subset

$$T_{fi}(X) \tag{3.690}$$

of $\mathcal{T}_{fi}(X)$ $\underline{\text{a}}$ set of invertible transformations under which f is invariant.

Exercise 3.86. Show that any bijection f is identical with the inverse function of its inverse function, that is,

$$\forall X, Y, f\,(f : X \rightleftarrows Y \;\Rightarrow (f^{-1})^{-1} = f). \tag{3.691}$$

The following Proposition shows how to construct a surjection on the basis of a given injection.

Proposition 3.213. *For any injection $f : X \hookrightarrow Y$ and any element $x' \in X$ it is true that the union of the inverse function of f and the Cartesian product $(Y \setminus \operatorname{ran}(f)) \times \{x'\}$ is a surjection from Y to X, that is,*

$$\forall X, Y, f, x'\,([f : X \hookrightarrow Y \wedge x' \in X] \;\Rightarrow\; f^{-1} \cup [(Y \setminus \operatorname{ran}(f)) \times \{x'\}] : Y \twoheadrightarrow X). \tag{3.692}$$

Proof. We let X, Y, f and x' be arbitrary, assume that f is an injection from X to Y, and assume moreover that $x' \in X$ is true. It then follows with (3.676) that f^{-1} is a function from $\mathrm{ran}(f)$ to X, and the Cartesian product $g_{x'} = (Y \setminus \mathrm{ran}(f)) \times \{x'\}$ is the constant function from $Y \setminus \mathrm{ran}(f)$ to $\{x'\}$, by definition. Since the domain $\mathrm{ran}(f)$ of the function f^{-1} and the domain $Y \setminus \mathrm{ran}(f)$ of the constant function $g_{x'}$ are disjoint sets because of (2.111), it follows with Exercise 3.73 that f^{-1} and $g_{x'}$ are compatible functions. Consequently, the pair formed by these functions constitutes a compatible set of functions due to Proposition 3.174, so that the union (3.692) is a function with domain $\mathrm{ran}(f) \cup [Y \setminus \mathrm{ran}(f)]$ according to Theorem 3.175. As we initially assumed f to be a function with codomain Y, we have $\mathrm{ran}(f) \subseteq Y$, which implies with (2.263)

$$[Y \setminus \mathrm{ran}(f)] \cup \mathrm{ran}(f) = Y,$$

so that the domain of g is clearly Y. We now apply Corollary 3.191 to prove $g : Y \twoheadrightarrow X$. To do this, we verify

$$\forall x\,(x \in X \Leftrightarrow \exists y\,(g(y) = x)). \tag{3.693}$$

We let x be arbitrary and assume first $x \in X$ to be true. Since f is a function from X to Y, the function value $\bar{y} = f(x)$ exists uniquely in Y. Then, we obtain $x = f^{-1}(\bar{y})$ with Proposition 3.209, which equation we may also write as $(\bar{y}, x) \in f^{-1}$. Since $f^{-1} \subseteq g$ holds due to (3.692) and Proposition 2.67, it now follows that $(\bar{y}, x) \in g$ holds as well, which finding we may also write as $x = g(\bar{y})$, because g is a function. This equation shows that there exists an y with $g(y) = x$, so that the first part ('$\Rightarrow$') of the equivalence in (3.693) holds.

To establish the second part ('$\Leftarrow$'), we now assume that there is an element, say $\bar{y}$, satisfying $g(\bar{y}) = x$. Thus, $(\bar{y}, x) \in g$ holds, which implies with (3.692) and the definition of the union of two sets that the disjunction $(\bar{y}, x) \in f^{-1} \vee (\bar{y}, x) \in g_{x'}$ is true. On the one hand, if $(\bar{y}, x) \in f^{-1}$ holds, i.e. $x = f^{-1}(\bar{y})$, then we obtain $\bar{y} = f(x)$ with Proposition 3.209, i.e. $(x, \bar{y}) \in f$. Consequently, $x \in \mathrm{dom}(f)$ $[= X]$ follows to be true by definition of a domain, so that the desired $x \in X$ holds in the first case.

On the other hand, if the second part $(\bar{y}, x) \in g_{x'}$ of the preceding disjunction is true, we obtain on the one hand $\bar{y} \in \mathrm{dom}(g_{x'})$ with the definition of a domain, which shows that $g_{x'}$ is a constant function with nonempty domain. On the other hand, we obtain $x \in \mathrm{ran}(g_{x'})$ $[= \{x'\}]$ with the definition of a range and the fact that the nonempty constant function $g_{x'}$ is onto $\{x'\}$ according to Proposition 3.193. Then, $x \in \{x'\}$ implies $x = x'$ with (2.169), so that the initial assumption $x' \in X$ gives $x \in X$, as desired.

This completes the proof of the equivalence in (3.693), and since x is arbitrary, the universal sentence (3.693) follows then to be true. Consequently, g is a surjection from Y to X according to Corollary 3.191. As X, Y, f and x' were arbitrary, we may then infer from this the truth of the proposed universal sentence. □

To construct, conversely, an injection from a given surjection, we must be able to pick out unspecified elements from the sets of a given set system.

Axiom 3.3 (Axiom of Choice). It is true for any set system $\mathcal{K}$ consisting of nonempty sets that there exists a function f with domain $\mathcal{K}$ and codomain $\bigcup\mathcal{K}$ such that the function value at any set K in $\mathcal{K}$ is an element of K, that is,

$$\forall \mathcal{K}\,(\emptyset \notin \mathcal{K} \Rightarrow \exists f\,(f : \mathcal{K} \to \bigcup \mathcal{K} \,\wedge\, \forall K\,(K \in \mathcal{K} \Rightarrow f(K) \in K))). \quad (3.694)$$

The Axiom of Choice allows us to construct a function from any given binary relation in such a way that their domain coincide.

Proposition 3.214. *It is true for any binary relation that there exists a function included in R with equal domain, that is,*

$$\begin{aligned}&\forall R\,(R \text{ is a binary relation}\\ &\quad \Rightarrow\ \exists F\,(F \text{ is a function} \,\wedge\, F \subseteq R \,\wedge\, \mathrm{dom}(F) = \mathrm{dom}(R))).\end{aligned} \quad (3.695)$$

Proof. We take an arbitrary set R, and we assume R to be a binary relation. Let us verify now the universal sentence

$$\forall a\,(a \in \mathrm{dom}(R) \Rightarrow \exists! B\,(\forall b\,(b \in B \Leftrightarrow [b \in \mathrm{ran}(R) \,\wedge\, (a,b) \in R]))). \quad (3.696)$$

Letting a be arbitrary and assuming $a \in \mathrm{dom}(R)$ to be true, we can evidently prove the uniquely existential by means of the Axiom of Specification and the Equality Criterion for sets (in the usual way). According to Function definition by replacement, there exists then a unique function f with domain $\mathrm{dom}(R)$ such that

$$\forall a\,(a \in \mathrm{dom}(R) \Rightarrow \forall b\,(b \in f(a) \Leftrightarrow [b \in \mathrm{ran}(R) \,\wedge\, (a,b) \in R])). \quad (3.697)$$

Since the range of f is included in itself according to (2.10), we may take $\mathrm{ran}(f)$ as a codomain of f, so that $f : \mathrm{dom}(R) \to \mathrm{ran}(f)$. Next, we demonstrate the truth of $\emptyset \notin \mathrm{ran}(f)$, via the verification of the universal sentence

$$\forall B\,(B \in \mathrm{ran}(f) \Rightarrow B \neq \emptyset). \quad (3.698)$$

We let B be arbitrary, assuming $B \in \mathrm{ran}(f)$ to be true. The definitions of a range and of a domain imply then the existence of a particular constant

$\bar{a} \in \mathrm{dom}(f)$ [$= \mathrm{dom}(R)$] such that $(\bar{a}, B) \in f$. We thus have $\bar{a} \in \mathrm{dom}(R)$ and, using function notation, $B = f(\bar{a})$. The former implies (by definition of a domain) that there exists a particular constant $\bar{b}$ with $(\bar{a}, \bar{b}) \in R$. This further implies $\bar{b} \in \mathrm{ran}(R)$ by definition of a range, so that $\bar{b} \in B$ follows to be true with (3.697). This finding clearly demonstrates the truth of the desired consequent $B \neq \emptyset$ of the implication in (3.698), in which B is arbitrary, so that the universal sentence (3.698) follows to be true. Consequently, we obtain the suggested negation $\emptyset \notin \mathrm{ran}(f)$ with (2.5).

This negation allows us now to apply the Axiom of Choice and to infer the existence of a particular function $\bar{g} : \mathrm{ran}(f) \to \bigcup \mathrm{ran}(f)$ such that

$$\forall B\, (B \in \mathrm{ran}(f) \Rightarrow \bar{g}(B) \in B). \tag{3.699}$$

Then, the composition $\bar{F} = \bar{g} \circ f$ constitutes a function from $\mathrm{dom}(R)$ to $\bigcup \mathrm{ran}(f)$, according to Proposition 3.178.

We establish now the inclusion $\bar{F} \subseteq R$ by means of the definition of a subset. To do this, we take an arbitrary Z, and we assume that $Z \in \bar{F}$ is true. Since $\bar{F}$ is a binary relation, there are particular constants $\bar{a}, \bar{b}$ for which $(\bar{a}, \bar{b}) = Z$ holds. Thus, substitution yields $(\bar{a}, \bar{b}) \in \bar{F}$, which we may write in function notation as $\bar{b} = \bar{F}(\bar{a})$. Recalling that $\bar{F}$ denotes the composed function $\bar{g} \circ f$, we can also write this equation in the form $\bar{b} = \bar{g}(f(\bar{a}))$. We note that the previously found $(\bar{a}, \bar{b}) \in \bar{F}$ implies $\bar{a} \in \mathrm{dom}(R)$ [$= \mathrm{dom}(\bar{F})$] by definition of a domain. Here, $\bar{a}$ is also in the domain of the function f, and $f(\bar{a})$ is evidently an element of the range of f. Consequently, [$\bar{b} =$] $\bar{g}(f(\bar{a})) \in f(\bar{a})$ is implied according to (3.699). The resulting $\bar{b} \in f(\bar{a})$ implies in addition $(\bar{a}, \bar{b}) \in R$ with (3.697), so that $Z \in R$ follows to be true via substitution. Since Z was arbitrary in $\bar{F}$, we may now infer from this the truth of the inclusion $\bar{F} \subseteq R$.

We thus proved that there exists a function F with domain $\mathrm{dom}(F) = \mathrm{dom}(R)$ and satisfying the inclusion $F \subseteq R$. As R was initially arbitrary, we may therefore conclude that the proposition holds, as claimed. $\square$

The next theorem gives another typical application of the Axiom of Choice.

Theorem 3.215. *For any surjection g from a set Y to a set X there exists an injection f from X to Y, that is,*

$$\forall X, Y, g\, (g : Y \twoheadrightarrow X \;\Rightarrow\; \exists f\, (f : X \hookrightarrow Y)) \tag{3.700}$$

Proof. We let X, Y and g be arbitrary sets and assume that $g : Y \twoheadrightarrow X$ holds, so that $\mathrm{dom}(g) = Y$ and $\mathrm{ran}(g) = X$ are true by definition of a surjection. We now consider the two cases $g = \emptyset$ and $g \neq \emptyset$. In the first case, $g = \emptyset$ implies $Y = \mathrm{dom}(g) = \emptyset$ and $X = \mathrm{ran}(g) = \emptyset$ with Exercise 3.20 and the assumption that g is a surjection with range X. Then, because of $X = \emptyset$, we see in light of Proposition 3.151, there exists a (unique) function $f : X \to Y$, which is an injection according to Exercise 3.76. This proves the proposition for the first case.

In the other case that $g \neq \emptyset$ holds, we will use the inverse g^{-1} to construct an injection from X to Y. Let us first observe that $g \neq \emptyset$ implies $[Y =] \ \mathrm{dom}(g) \neq \emptyset$ and $[X =] \ \mathrm{ran}(g) \neq \emptyset$ (applying again Exercise 3.20 in connection with the surjectivity of g), and moreover $g^{-1} \neq \emptyset$ with Theorem 3.41b). It follows with Corollary 3.42 also that $g^{-1} \subseteq X \times Y$ holds, and moreover that $\mathrm{dom}(g^{-1}) = \mathrm{ran}(g)$ $[= X]$ is true because of Theorem 3.44. Next, we observe that g^{-1} is not necessarily a function, as there might exist ordered pairs (y_1, x), (y_2, x) in g, so that $(x, y_1), (x, y_2)$ are elements of g^{-1} with multiple values for one element x of the domain of g^{-1}. Using now the Axiom of Specification in connection with the Equality Criterion for sets, we may establish the unique existence of a set (system) $\mathcal{K}$ containing precisely any element K of $\mathcal{P}(g^{-1})$, i.e. any subset K of g^{-1}, such that K is the restriction of g^{-1} to some x in X, that is,

$$\exists! \mathcal{K} \forall K \, (K \in \mathcal{K} \Leftrightarrow [K \in \mathcal{P}(g^{-1}) \ \wedge \ \exists x \, (x \in X \ \wedge \ g^{-1} \restriction \{x\} = K)]).$$

Thus, the set $\mathcal{K}$ satisfies

$$\forall K \, (K \in \mathcal{K} \Leftrightarrow [K \in \mathcal{P}(g^{-1}) \ \wedge \ \exists x \, (x \in X \ \wedge \ g^{-1} \restriction \{x\} = K)]). \quad (3.701)$$

We now prove that $\emptyset \notin \mathcal{K}$ is true. For this purpose, we verify the equivalent

$$\forall K \, (K \in \mathcal{K} \Rightarrow K \neq \emptyset), \quad (3.702)$$

using Proposition 2.2. We let K be arbitrary and assume $K \in \mathcal{K}$ to be true, which implies with (3.701) in particular that there is an element, say $\bar{x}$, with $\bar{x} \in X$ and $g^{-1} \restriction \{\bar{x}\} = K$. Recalling that $X = \mathrm{dom}(g^{-1})$ holds and observing the evident truth of $\bar{x} \in \{\bar{x}\}$, we thus obtain the true conjunction $\bar{x} \in \mathrm{dom}(g^{-1}) \ \wedge \ \bar{x} \in \{\bar{x}\}$, which in turn yields with the definition of the intersection of two sets $\bar{x} \in \mathrm{dom}(g^{-1}) \cap \{\bar{x}\}$. Clearly, the intersection is thus nonempty, so that the restriction $K = g^{-1} \restriction \{\bar{x}\}$ is also nonempty according to (3.102). This proves the implication in (3.702), and since K was arbitrary, we may therefore infer from this the truth of the universal sentence (3.702), which then gives $\emptyset \notin \mathcal{K}$ (according to Proposition 2.2).

We may therefore apply the Axiom of Choice to infer from the preceding finding that there exists a function, say $\bar{F}$, such that $\bar{F} : \mathcal{K} \to \bigcup \mathcal{K}$ and

$$\forall K \, (K \in \mathcal{K} \Rightarrow \bar{F}(K) \in K) \quad (3.703)$$

hold. Since $\bigcup\mathcal{K}$ is codomain of $\bar{F}$, we see that $\mathrm{ran}(\bar{F}) \subseteq \bigcup\mathcal{K}$. Next, we prove that $\bigcup\mathcal{K} \subseteq X \times Y$ also holds. To do this, we apply the definition of a subset and verify the equivalent

$$\forall Z\,(Z \in \bigcup\mathcal{K} \Rightarrow Z \in X \times Y). \tag{3.704}$$

We let Z be arbitrary and assume $Z \in \bigcup\mathcal{K}$ to be true, so that there exists – by definition of the union of a set system – a set in $\mathcal{K}$, say $\bar{K}$, with $Z \in \bar{K}$. Here, $\bar{K} \in \mathcal{K}$ implies with (3.702) in particular $\bar{K} \in \mathcal{P}(g^{-1})$ and therefore $\bar{K} \subseteq g^{-1}$ by definition of a power set. Recalling now that the inclusion $g^{-1} \subseteq X \times Y$ also holds, we obtain with the transitivity of $\subseteq$ the inclusion $\bar{K} \subseteq X \times Y$. With this, the previously established $Z \in \bar{K}$ implies the desired consequent $Z \in X \times Y$ by definition of a subset. Since Z was arbitrary, we may therefore conclude that the universal sentence (3.704) is true, which in turn implies $\bigcup\mathcal{K} \subseteq X \times Y$ (using again the definition of a subset). Together with the previously found $\mathrm{ran}(\bar{F}) \subseteq \bigcup\mathcal{K}$, this finding further implies $\mathrm{ran}(\bar{F}) \subseteq X \times Y$ (again with the transitivity of $\subseteq$).

Consequently, we may apply the Function Criterion to verify that $\mathrm{ran}(\bar{F})$ is a function from X to Y. For this purpose, we prove

$$\forall x\,(x \in X \Rightarrow \exists! y\,(y \in Y \ \wedge\ (x, y) \in \mathrm{ran}(\bar{F}))). \tag{3.705}$$

We let $\bar{x} \in X$ be arbitrary and establish first the existential part

$$\exists y\,(y \in Y \ \wedge\ (\bar{x}, y) \in \mathrm{ran}(\bar{F})). \tag{3.706}$$

Defining the restriction $\bar{K} = g^{-1} \restriction \{\bar{x}\}$, we thus see that there exists an x which satisfies the conjunction $x \in X \wedge g^{-1} \restriction \{x\} = \bar{K}$. Moreover, because $g^{-1} \restriction \{\bar{x}\} \subseteq g^{-1}$ holds according to Corollary 3.23, we obtain $\bar{K} \subseteq g^{-1}$ and therefore $\bar{K} \in \mathcal{P}(g^{-1})$ by definition of a power set. Together with the preceding existential sentence, this further implies $\bar{K} \in \mathcal{K}$ with (3.702), so that $g^{-1} \restriction \{\bar{x}\} \in \mathcal{K}$ holds. This in turn implies $\bar{F}(\bar{K}) \in g^{-1} \restriction \{\bar{x}\}$ with (3.703), so that there exist – by definition of a restriction – elements, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in \{\bar{x}\}$ and $(\bar{a}, \bar{b}) = \bar{F}(\bar{K})$. Here, we may write the equation also as $(\bar{K}, (\bar{a}, \bar{b})) \in \bar{F}$, so that $(\bar{a}, \bar{b}) \in \mathrm{ran}(\bar{F})$ holds by definition of a range. As the previously found $\bar{a} \in \{\bar{x}\}$ yields $\bar{a} = \bar{x}$ with (2.169), substitution yields $(\bar{x}, \bar{b}) \in \mathrm{ran}(\bar{F})$. Recalling now $\mathrm{ran}(\bar{F}) \subseteq X \times Y$, we then obtain with the definition of a subset $(\bar{x}, \bar{b}) \in X \times Y$, so that $\bar{b} \in Y$ follows in particular to be true with the definition of the Cartesian product of two sets. We thus showed that there exists an y which satisfies $y \in Y$ and $(\bar{x}, y) \in \mathrm{ran}(\bar{F})$, which proves the existential part (3.706). To establish the uniqueness part, we verify accordingly

$$\forall y, y'\,([y \in Y \ \wedge\ (\bar{x}, y) \in \mathrm{ran}(\bar{F}) \ \wedge\ y' \in Y \ \wedge\ (\bar{x}, y') \in \mathrm{ran}(\bar{F})] \Rightarrow y = y'). \tag{3.707}$$

Letting $\bar{y}$ and $\bar{y}'$ be arbitrary, we assume $\bar{y}, \bar{y}'$ and $(\bar{x}, \bar{y}), (\bar{x}, \bar{y}') \in \mathrm{ran}(\bar{F})$ to be true. The latter assumptions imply with the definition of a range that there exist elements, $\bar{K}$ and $\bar{K}'$, with

$$(\bar{K}, (\bar{x}, \bar{y})) \in \bar{F}, \tag{3.708}$$
$$(\bar{K}', (\bar{x}, \bar{y}')) \in \bar{F}. \tag{3.709}$$

On the one hand, $\bar{K}, \bar{K}' \in \mathrm{dom}(\bar{F})$ $[= \mathcal{K}]$ follows to be true by definition of a domain, and on the other hand we may write

$$(\bar{x}, \bar{y}) = \bar{F}(\bar{K}),$$
$$(\bar{x}, \bar{y}') = \bar{F}(\bar{K}').$$

Since $\bar{K}, \bar{K}' \in \mathcal{K}$ implies with (3.703) the truth of $\bar{F}(\bar{K}) \in \bar{K}$ and of $\bar{F}(\bar{K}') \in \bar{K}'$, substitution based on the preceding equations yields

$$(\bar{x}, \bar{y}) \in \bar{K}, \tag{3.710}$$
$$(\bar{x}, \bar{y}') \in \bar{K}'. \tag{3.711}$$

Furthermore, $\bar{K}, \bar{K}' \in \mathcal{K}$ implies with (3.702) in particular that there are elements, say $\bar{\bar{x}}$ and $\bar{\bar{x}}'$, such that $\bar{\bar{x}}, \bar{\bar{x}}' \in X$ and the equations

$$g^{-1} \upharpoonright \{\bar{\bar{x}}\} = \bar{K} \tag{3.712}$$
$$g^{-1} \upharpoonright \{\bar{\bar{x}}'\} = \bar{K}' \tag{3.713}$$

are true. Now, (3.710) and (3.711) give via substitution based on these equations

$$(\bar{x}, \bar{y}) \in g^{-1} \upharpoonright \{\bar{\bar{x}}\}$$
$$(\bar{x}, \bar{y}') \in g^{-1} \upharpoonright \{\bar{\bar{x}}'\}$$

By definition of a restriction, we therefore obtain in particular $\bar{x} \in \{\bar{\bar{x}}\}$ as well as $\bar{x} \in \{\bar{\bar{x}}'\}$, so that the equations $\bar{x} = \bar{\bar{x}}$ and $\bar{x} = \bar{\bar{x}}'$ follow to be true with (2.169). We may then apply substitutions to (3.712) and (3.713), that is,

$$\bar{K} = g^{-1} \upharpoonright \{\bar{\bar{x}}\} = g^{-1} \upharpoonright \{\bar{x}\} = g^{-1} \upharpoonright \{\bar{\bar{x}}'\} = \bar{K}',$$

which equations yield $\bar{K} = \bar{K}'$. Consequently, we may write (3.709) as $(\bar{K}, (\bar{x}, \bar{y}')) \in \bar{F}$, which implies together with (3.708) and the fact that $\bar{F}$ is a function $(\bar{x}, \bar{y}) = (\bar{x}, \bar{y}')$. This equation finally gives the desired $\bar{y} = \bar{y}'$ with the Equality Criterion for ordered pairs. As $\bar{y}$ and $\bar{y}'$ were arbitrary, we may therefore conclude that the universal sentence (3.707) is true, which establishes the uniqueness part and thus the truth of the uniquely existential sentence in (3.705). Because $\bar{x}$ was also arbitrary, the universal sentence (3.705) follows then also to be true, so that $\bar{f} = \mathrm{ran}(\bar{F})$ is a function from X to Y according to the Function Criterion.

It now only remains for us to verify that the function $\bar{f} : X \to Y$ is an injection. To do this, we prove

$$\forall x, x' \, ([x, x' \in X \, \wedge \, \bar{f}(x) = \bar{f}(x')] \Rightarrow x = x'). \tag{3.714}$$

We let x and x' be arbitrary elements in X and assume $\bar{f}(x) = \bar{f}(x')$ to be true. Denoting this function value by $y = \bar{f}(x)$ and $y = \bar{f}(x')$, we may then write these equations as $(x, y), (x', y) \in \mathrm{ran}(\bar{F})$. By definition of a range, there exist elements, say $\bar{K}$ and $\bar{K}'$, such that

$$(\bar{K}, (x, y)) \in \bar{F},$$
$$(\bar{K}', (x', y)) \in \bar{F}.$$

Then, we obtain on the one hand $\bar{K}, \bar{K}' \in \mathrm{dom}(\bar{F})$ $[= \mathcal{K}]$ (by definition of a domain) and on the other hand

$$(x, y) = \bar{F}(\bar{K}),$$
$$(x', y) = \bar{F}(\bar{K}').$$

As $\bar{K}, \bar{K}' \in \mathcal{K}$ implies $\bar{F}(\bar{K}) \in \bar{K}$ as well as $\bar{F}(\bar{K}') \in \bar{K}'$ with (3.703), we then obtain via substitution

$$(x, y) \in \bar{K}, \tag{3.715}$$
$$(x', y) \in \bar{K}'. \tag{3.716}$$

Moreover, $\bar{K}, \bar{K}' \in \mathcal{K}$ implies with (3.702) in particular $\bar{K}, \bar{K}' \in \mathcal{P}(g^{-1})$ and therefore $\bar{K} \subseteq g^{-1}$ as well as $\bar{K}' \subseteq g^{-1}$ with the definition of a power set. With these inclusions, (3.715) and (3.716) imply

$$(x, y) \in g^{-1},$$
$$(x', y) \in g^{-1},$$

and therefore $(y, x), (y, x') \in g$ with Proposition 3.43. Since g is a function, the preceding finding yields $x = x'$, completing the proof of the implication in (3.714). As x and x' are arbitrary, we may now infer from this the truth of the universal sentence (3.714), and thus the injectivity of the function $\bar{f} : X \to Y$. We thus showed that an injection $f : X \to Y$ exists, and since X, Y and g were initially arbitrary, we may finally conclude that the theorem is true. $\square$

3.4.5. Images and inverse images

Definition 3.54 ((Direct) image). For any function f from a set X to a set Y and for any subset A of X we call the range of the restriction of f to A, symbolically

$$f[A] = \mathrm{ran}(f \upharpoonright A), \tag{3.717}$$

the (*direct*) *image* of A under f.

Recalling that the restriction of a function to its domain is the function itself (see Note 3.19), we immediately obtain the following characterization of the range of a function as the image of its domain.

Corollary 3.216. *It is true that the image of the domain of/under any function is identical with the range of the function, that is,*

$$\forall X, Y, f\,(f : X \to Y \;\Rightarrow\; f[X] = \mathrm{ran}(f)). \tag{3.718}$$

The following proposition brings out more clearly how the image of a subset of a given function domain is determined.

Proposition 3.217. *It is true for any function f from a set X to a set Y and for any subset A of X that the value of f at any element of A is in the image of A under f, that is,*

$$\forall X, Y, f, A\,([f \in Y^X \wedge A \subseteq X] \Rightarrow \forall x\,(x \in A \Rightarrow f(x) \in f[A])). \tag{3.719}$$

Proof. We take arbitrary sets X, Y, f and A, we assume f to be an element of Y^X (i.e., to be a function from X to Y), and we assume the inclusion $A \subseteq X$ to be true. Thus, the image $f[A]$ of A under f is defined. Next, we take an arbitrary x and assume $x \in A$ to be true, so that $x \in X$ also holds by definition of a subset. Therefore, the function value $y = f(x)$ exists uniquely in Y, and we may write this equation also in the form $(x, y) \in f$. This implies in conjunction with the assumed $x \in A$ and the definition of a restriction $(x, y) \in f \upharpoonright A$, which shows in light of the definition of a range that $[f(x) =]\ y \in \mathrm{ran}(f \upharpoonright A)$ is true. This means according to the definition of an image that $f(x) \in f[A]$ holds, as desired. Here, x is arbitrary, so that the universal sentence with respect to x in (3.719) follows to be true. Since X, Y, f and A were initially also arbitrary, we may therefore conclude that the proposed universal sentence holds, as claimed. □

Corollary 3.218. *For any function f from a set X to a set Y and for any subset A of X it is true that the image of A under f is included in the range and the codomain of f, that is,*

$$\forall X, Y, f, A\,([f \in Y^X \wedge A \subseteq X] \Rightarrow [f[A] \subseteq \mathrm{ran}(f) \wedge f[A] \subseteq Y]). \tag{3.720}$$

Proof. Letting X and Y be arbitrary sets, f an arbitrary element of Y^X (so that $f : X \to Y$), and letting A be an arbitrary subset of X, we first observe in light of Corollary 3.23 that $f \upharpoonright A \subseteq f$ holds and that the restriction is itself a binary relation. These findings in turn imply with Proposition 3.34 that the inclusion $\mathrm{ran}(f \upharpoonright A) \subseteq \mathrm{ran}(f)$ is then true as well. Then, the definition of an image yields $f[A] \subseteq \mathrm{ran}(f)$. Since $\mathrm{ran}(f) \subseteq Y$ also holds by definition of a codomain, we obtain with the transitivity of $\subseteq$ the second desired inclusion $f[A] \subseteq Y$. As X, Y, f and A were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Note 3.29. In the particular case of a function $f : X \to Y$ and a singleton $A = \{x\}$ with $x \in X$, the corresponding image reads according to (3.642)

$$f[\{x\}] = \{f(x)\}. \tag{3.721}$$

Exercise 3.87. Show for function $f : X \to Y$ that the image of the empty set under f is empty, that is,

$$\forall X, Y, f\,(f \in Y^X \Rightarrow f[\emptyset] = \emptyset). \tag{3.722}$$

(Hint: Use (2.43), (3.717), (3.85) and (3.121).)

Exercise 3.88. Show that the image of any subset A of any set X under any function f from X to any set Y is nonempty iff the subset A is nonempty, that is,

$$\forall X, Y, f, A\,([f : X \to Y \,\wedge\, A \subseteq X] \Rightarrow [f[A] \neq \emptyset \Leftrightarrow A \neq \emptyset]). \tag{3.723}$$

(Hint: Use (2.42), (3.108), (3.81) and (3.719).)

Proposition 3.219. *For any functions $f : X \to Y$, $g : Y \to Z$ and any $A \subseteq X$ it is true that the image of the range of the restriction of f to A under g is identical with the range of the restriction of the composition of g and f to A, that is,*

$$\begin{aligned}&\forall X, Y, Z, f, g, A\,([f \in Y^X \,\wedge\, g \in Z^Y \,\wedge\, A \subseteq X]\\ &\quad \Rightarrow g[\mathrm{ran}(f \upharpoonright A)] = \mathrm{ran}([g \circ f] \upharpoonright A)).\end{aligned} \tag{3.724}$$

Proof. We let X, Y, Z, f, g and A be arbitrary sets, assume that f is a function from X to Y, furthermore that g is a function from Y to Z, and moreover that A is a subset of X. To prove the equation in (3.724), we apply the Equality Criterion for sets and verify accordingly

$$\forall z\,(z \in g[\mathrm{ran}(f \upharpoonright A)] \Leftrightarrow z \in \mathrm{ran}([g \circ f] \upharpoonright A)). \tag{3.725}$$

To do this, we let $\bar{z}$ be arbitrary and prove the first part ('⇒') of the equivalence directly, assuming

$$\bar{z} \in g[\operatorname{ran}(f \restriction A)] \tag{3.726}$$

to be true. By definition of an image, this assumption implies

$$\bar{z} \in \operatorname{ran}(g \restriction \operatorname{ran}(f \restriction A)) \tag{3.727}$$

and then, by definition of a range, that there exists an element, say $\bar{y}$, such that

$$(\bar{y}, \bar{z}) \in g \restriction \operatorname{ran}(f \restriction A). \tag{3.728}$$

This implies on, the one hand, in particular

$$(\bar{y}, \bar{z}) \in g \tag{3.729}$$

with the definition of a restriction and, on the other hand,

$$\bar{y} \in \operatorname{ran}(f \restriction A) \tag{3.730}$$

with the definition of a domain, since the assumption $g : Y \to Z$ implies with Proposition 3.164 that the restriction $g \restriction \operatorname{ran}(f \restriction A)$ is a function with domain $\operatorname{ran}(f \restriction A)$ (and codomain Z). Next, the sentence (3.730) implies (again by definition of a range) that there exists an element, say $\bar{x}$, with

$$(\bar{x}, \bar{y}) \in f \restriction A. \tag{3.731}$$

This implies on the one hand (by definition of a restriction)

$$(\bar{x}, \bar{y}) \in f, \tag{3.732}$$

and on the other hand (by definition of a domain)

$$\bar{x} \in A, \tag{3.733}$$

since the assumption $f : X \to Y$ implies (with Proposition 3.164) that the restriction $f \restriction A$ is a function with domain A. Now, the sentences (3.732) and (3.729) show that the existential sentence

$$\exists x, y, z\, ((x, y) \in f \,\wedge\, (y, z) \in g \,\wedge\, (x, z) = (\bar{x}, \bar{z})) \tag{3.734}$$

is true, which implies with the definition of a composition

$$(\bar{x}, \bar{z}) \in g \circ f. \tag{3.735}$$

The conjunction of (3.733) and (3.735) now gives with the definition of a restriction

$$(\bar{x}, \bar{z}) \in [g \circ f] \upharpoonright A, \tag{3.736}$$

and then finally (by definition of a range) the desired

$$\bar{z} \in \mathrm{ran}([g \circ f] \upharpoonright A). \tag{3.737}$$

Thus, the proof of the first part of the equivalence in (3.725) is complete.

To prove the second part ('$\Leftarrow$'), we apply the same arguments (plus one additional argument) in reversed order to obtain (3.726). Assuming now (3.737) to be true, there exists by definition of a range an element, say $\bar{x}$, such that (3.736) holds. This in turn implies (3.733) and (3.735) with the definition of a restriction. It now follows with the definition of a composition from (3.735) that (3.734) holds. Thus, there are elements, say $\bar{x}'$, $\bar{y}'$ and $\bar{z}'$, such that $(\bar{x}', \bar{y}') \in f$, $(\bar{y}', \bar{z}') \in g$ and $(\bar{x}', \bar{z}') = (\bar{x}, \bar{z})$ hold, because the ordered pair $(\bar{x}, \bar{z})$ if formed by the previously established elements $\bar{x}$ and $\bar{z}$. The preceding equation implies $\bar{x}' = \bar{x}$ as well as $\bar{z}' = \bar{z}$ with the Equality Criterion for ordered pairs. Performing substitution based on these equations, the previously obtained $(\bar{x}', \bar{y}') \in f$ and $(\bar{y}', \bar{z}') \in g$ imply (3.732) and (3.729), respectively. Since (3.733) and (3.732) are thus both true, it follows with the definition of a restriction that (3.731) also holds. This in turn implies (3.730) with the definition of a range. The conjunction of this and the previously found (3.729) now gives (3.728) with the definition of a restriction, then (3.727) with the definition of a range, and finally (3.726) with the definition of an image.

This completes the proof of the equivalence in (3.726), and since $\bar{z}$ is arbitrary, it follows that the universal sentence (3.726) is true. We may then infer from this that the sets $g[\mathrm{ran}(f \upharpoonright A)]$ and $\mathrm{ran}([g \circ f] \upharpoonright A)$ are identical (according to the Equality Criterion for sets). Since X, Y, Z, f, g and A were arbitrary, we may therefore conclude that the proposition is true. □

Since the composition $g \circ f$ of any functions $f : X \to Y$ and $g : Y \to Z$ constitutes a function from X to Z according to Proposition 3.178, we may immediately apply the definition of an image to the preceding proposition to obtain the following simpler statement.

Corollary 3.220. *It is true that*

$$\forall X, Y, Z, f, g, A\,([f \in Y^X \wedge g \in Z^Y \wedge A \subseteq X] \Rightarrow g[f[A]] = (g \circ f)[A]). \tag{3.738}$$

Exercise 3.89. Demonstrate the truth of the following universal sentence.

$$\forall X,Y,f,A\,([f\in Y^X \wedge g\in Z^Y \wedge A\subseteq X] \\ \Rightarrow \forall x\,(x\in A\Rightarrow g(f(x))\in g[f[A]])). \tag{3.739}$$

(Hint: Apply (3.719) and (3.720).)

In the particular case of $A=X$ we obtain the following characterization of the range of a composition.

Corollary 3.221. *For any functions $f:X\to Y$ and $g:Y\to Z$, the image of the range of f under g is identical with the range of the composition of g and f, that is,*

$$\forall X,Y,Z,f,g\,([f\in Y^X \wedge g\in Z^Y]\Rightarrow g[\mathrm{ran}(f)]=\mathrm{ran}(g\circ f)). \tag{3.740}$$

Proof. Letting $f:X\to Y$ and $g:Y\to Z$ be arbitrary functions, it follows with the fact $X\subseteq X$ (see Exercise 2.10) in view of (3.724) that

$$g[\mathrm{ran}(f\restriction X)]=\mathrm{ran}([g\circ f]\restriction X) \tag{3.741}$$

holds. Since $f\restriction X$ and $g\circ f$ are functions with domain X due to Proposition 3.164 and Proposition 3.178, it follows with (3.103) that $f\restriction X=f$ as well as $[g\circ f]\restriction X=g\circ f$, so that (3.741) implies via substitution the equation in (3.740), which then follows to be true for any sets X, Y, Z, f and g. □

Theorem 3.222. *The following sentences are true for any function $f:X\to Y$ and any subset $B\subseteq Y$.*

a) There exists a unique set $f^{-1}[B]$ consisting of all the elements x in X for which the function value $f(x)$ is in B.

b) The set $f^{-1}[B]$ satisfies also

$$\forall x\,(x\in f^{-1}[B]\Leftrightarrow f(x)\in B). \tag{3.742}$$

Proof. Letting X, Y, f and B be arbitrary sets such that $f:X\to Y$ and $B\subseteq Y$ hold, the Axiom of Specification yields in connection with the Equality Criterion the true uniquely existential sentence

$$\exists! f^{-1}[B]\,\forall x\,(x\in f^{-1}[B]\Leftrightarrow[x\in X \wedge f(x)\in B]),$$

which proves a). Thus, the set $f^{-1}[B]$ satisfies

$$\forall x\,(x\in f^{-1}[B]\Leftrightarrow[x\in X \wedge f(x)\in B]). \tag{3.743}$$

Concerning b), we let x be arbitrary and assume first $x \in f^{-1}[B]$, which implies with (3.743) in particular the desired $f(x) \in B$. Conversely, we now assume $f(x) \in B$ to be true, which expression makes only sense in case the function value $y = f(x)$ is specified. Since we may write this as $(x, y) \in f$, it follows by definition of a domain that $x \in \mathrm{dom}(f)$ $[= X]$ holds. Thus, the conjunction of $x \in X$ and $f(x) \in B$ is true, which in turn implies $x \in f^{-1}[B]$ with (3.743). As x was arbitrary, we may therefore conclude that the universal sentence (3.743) is true, so that the proof of b) is complete. Because X, Y, f and B were arbitrary, we may finally conclude that the theorem is true. $\square$

Note 3.30. Since $x \in f^{-1}[B]$ implies with (3.743) in particular $x \in X$ for any x, we obtain $f^{-1}[B] \subseteq X$ by definition of a subset, so that the set $f^{-1}[B]$ is included in the domain X of a function $f : X \to Y$ (for a subset B of the codomain Y).

Definition 3.55 (Inverse image/preimage). For any function $f : X \to Y$ and any subset $B \subseteq Y$ we call the set $f^{-1}[B]$ consisting of all elements x in X for which $f(x)$ is in B the *inverse image* or *preimage* of B under f. We symbolize this set also by

$$\{x : f(x) \in B\}. \tag{3.744}$$

Note 3.31. For any function $f : X \to Y$, we have $\emptyset \subseteq Y$ with (2.43) and $Y \subseteq Y$ with (2.10), so that the preimages of $\emptyset$ and Y under f are defined.

Exercise 3.90 (Inverse image of the empty set and of the codomain). Verify for any function $f : X \to Y$ that

a) the inverse image of the empty set is also empty, that is,

$$f^{-1}[\emptyset] = \emptyset. \tag{3.745}$$

(Hint: Apply Definition 2.6 and Method 1.12.)

b) the inverse image of the codomain is the domain, that is,

$$f^{-1}[Y] = X. \tag{3.746}$$

(Hint: Apply the Equality Criterion for sets.)

The following proposition shows that the 'composition' of image and inverse image does not produce a strict identity like the composition of function and inverse function.

Proposition 3.223. *For any function $f : X \to Y$ and any subset $B \subseteq Y$ it is true that the image of the inverse image of B (under f) is included in B, that is,*

$$\forall X, Y, f, B \left([f \in Y^X \ \land \ B \subseteq Y] \Rightarrow f[f^{-1}[B]] \subseteq B \right). \tag{3.747}$$

Proof. We let X, Y, f and B be arbitrary sets, assume f to be an element of Y^X, and assume B to be a subset of Y. To prove that this implies $f[f^{-1}[B]] \subseteq B$, we verify (using the definition of a subset)

$$\forall y \left(y \in f[f^{-1}[B]] \Rightarrow y \in B \right). \tag{3.748}$$

For this purpose, we let y be arbitrary and assume $y \in f[f^{-1}[B]]$. By definition of an image, the assumption implies $y \in \operatorname{ran}(f \restriction f^{-1}[B])$, and the definition of a range shows then that there exists an element, say $\bar{x}$, such that $(\bar{x}, y) \in f \restriction f^{-1}[B]$ holds. This implies with the definition of a restriction $(\bar{x}, y) \in f$ and $\bar{x} \in f^{-1}[B]$, where the former finding can be written in function notation as $y = f(\bar{x})$ and where the latter implies $f(\bar{x}) \in B$ by definition of an inverse image. Combining these new findings via substitution yields $y \in B$, which completes the proof of the implication in (3.748). As y was arbitrary, we may therefore conclude that (3.748) is true, so that $f[f^{-1}[B]] \subseteq B$ holds indeed, and this in turn proves the implication in (3.747). Finally, since X, Y, f and B are arbitrary, we now conclude that (3.747) holds, as proposed. □

Exercise 3.91. Show that any subset of a set Y is identical with the image of the inverse image of B under any function onto Y, that is,

$$\forall X, Y, f, B \left([f : X \twoheadrightarrow Y \ \land \ B \subseteq Y] \Rightarrow f[f^{-1}[B]] = B \right). \tag{3.749}$$

(Hint: Apply the Axiom of Extension, using (3.747) and (3.630).)

Proposition 3.224. *For any function $f : X \to Y$, any subset A of X and any subset B of Y it is true that, if the image of A (under f) is included in B, then A is included in the inverse image of B (under f), that is,*

$$\forall X, Y, f, A, B \left([f \in Y^X \land A \subseteq X \land B \subseteq Y] \Rightarrow \big(f[A] \subseteq B \Rightarrow A \subseteq f^{-1}[B] \big) \right). \tag{3.750}$$

Proof. We let X, Y be arbitrary sets, f an arbitrary element of Y^X, A an arbitrary subset of X, and B an arbitrary subset of Y. Next, we assume $f[A] \subseteq B$, or equivalently

$$\forall y \left(y \in f[A] \Rightarrow y \in B \right), \tag{3.751}$$

(using the definition of a subset), and verify $A \subseteq f^{-1}[B]$, i.e.

$$\forall x\,(x \in A \Rightarrow x \in f^{-1}[B]), \tag{3.752}$$

For this purpose, we let x be arbitrary, assume $x \in A$, and show that this implies $x \in f^{-1}[B]$. We first observe that the restriction $f \restriction A$ is a function with domain A (see Proposition 3.164). Then, by definition of a function, there exists a unique function value $y = f \restriction A(x)$, so that $(x, y) \in f \restriction A$. This implies on the one hand $(x, y) \in f$ with the definition of a restriction, and thus $y = f(x)$. On the other hand, it follows by definition of a range that $y \in \mathrm{ran}(f \restriction A)$ holds, and therefore $y \in f[A]$ by definition of a direct image. This in turn implies $y \in B$ with (3.751) and consequently $f(x) \in B$ with the previously established equation $y = f(x)$. Now, $f(x) \in B$ implies the desired $x \in f^{-1}[B]$ with the definition of an inverse image. Then, since x is arbitrary, we conclude that (3.752) is true, which proves $A \subseteq f^{-1}[B]$. As X, Y, f, A and B were also arbitrary, we finally conclude that the proposed universal sentence (3.750) is true. □

Exercise 3.92. Verify the following implication for any function $f : X \to Y$, any subset A of X and any subset B of Y. If A is included in the inverse image of B (under f), then the image of A (under f) is included in B, that is,

$$\forall X, Y, f, A, B\,([f \in Y^X \wedge A \subseteq X \wedge B \subseteq Y] \Rightarrow \big(A \subseteq f^{-1}[B] \Rightarrow f[A] \subseteq B\big)). \tag{3.753}$$

Proposition 3.225. *For any constant function $g_c : X \to Y$ and any subset $B \subseteq Y$, it is true that the inverse image of B under g_c is defined. Moreover, $g_c^{-1}[B] = X$ or $g_c^{-1}[B] = \emptyset$ holds.*

Proof. We let X, Y, c, g_c, B be arbitrary and assume that c is an element of Y, that g_c is the constant function from X to $\{c\}$, and that B is a subset of Y. Since $c \in Y$ implies $\{c\} \subseteq Y$ with (2.184), we see that Y is a codomain of g_c, so that we have $g_c : X \to Y$. As we also assumed $B \subseteq Y$ to be true, we then see that $g_c^{-1}[B]$ is defined. We now consider the two cases $c \in B$ and $c \notin B$.

In case $c \in B$ is true, we may establish $g_c^{-1}[B] = X$ by means of the Equality Criterion for sets. To do this, we prove

$$\forall x\,(x \in g_c^{-1}[B] \Leftrightarrow x \in X). \tag{3.754}$$

Letting x be arbitrary, we see on the one hand that assuming $x \in g_c^{-1}[B]$ to be true implies $x \in X$ by definition of an inverse image. Assuming conversely $x \in X$ to hold, we obtain with (3.534) the function value

$g_c(x) = c$ [$\in B$]. Then, $g_c(x) \in B$ implies $x \in g_c^{-1}[B]$ with the definition of an inverse image. Thus, the equivalence in (3.754) is true, and as x was arbitrary, we may therefore conclude that (3.754) holds, so that the sets $g_c^{-1}[B]$ and X are indeed equal.

In the other case that $c \notin B$ is true, we establish $g_c^{-1}[B] = \emptyset$ by verifying

$$\forall x\,(x \notin g_c^{-1}[B]). \tag{3.755}$$

For this purpose, we take an arbitrary x and prove $x \notin g_c^{-1}[B]$ by contradiction, assuming $\neg x \notin g_c^{-1}[B]$ to hold, so that $x \in g_c^{-1}[B]$ follows to be true with the Double Negation Law. We then obtain with the definition of an inverse image $x \in X$ and $g_c(x) \in B$. Here, $x \in X$ yields $g_c(x) = c$ with (3.534). With this equation, $g_c(x) \in B$ gives $c \in B$ via substitution, which is in contradiction to the current case assumption $c \notin B$. Thus, the proof of $x \notin g_c^{-1}[B]$ is complete, and since x is arbitrary, we may infer from this the truth of the universal sentence (3.755), which in turn implies $g_c^{-1}[B] = \emptyset$ with the definition of the empty set.

As X, Y, c, g_c and B were arbitrary, we may finally conclude that the proposition is true. □

Proposition 3.226. *For any sets X, Y and any surjection $f : X \twoheadrightarrow Y$ the inverse image (under f) of the singleton formed by any element c of Y is nonempty, i.e.*

$$\forall X, Y, f\,(f : X \twoheadrightarrow Y \;\Rightarrow \forall c\,(c \in Y \Rightarrow f^{-1}[\{c\}] \neq \emptyset)). \tag{3.756}$$

Proof. We let X and Y be arbitrary sets and f an arbitrary surjection from X to Y, so that $\mathrm{ran}(f) = Y$ holds by definition of a surjection. Next, we let c be an arbitrary element of Y, so that the preceding equation gives $c \in \mathrm{ran}(f)$. By definition of a range, there then exists a constant, say $\bar{x}$, such that $(\bar{x}, c) \in f$ holds, which then implies $\bar{x} \in \mathrm{dom}(f)$ with the definition of a domain, so that $\bar{x} \in X$. We may write $(\bar{x}, c) \in f$ also as $f(\bar{x}) = c$, which gives $f(\bar{x}) \in \{c\}$ with (2.169), and consequently $\bar{x} \in f^{-1}[\{c\}]$ with the definition of an inverse image. This shows that the inverse image $f^{-1}[\{c\}]$ is nonempty. As c is arbitrary, we therefore conclude that the universal sentence with respect to c in (3.756) holds. Because X, Y and f were also arbitrary, we then further conclude that the proposed universal sentence (3.756) holds. □

Exercise 3.93. Show for any function $f : X \to Y$ that the inverse image of the singleton formed by an element of Y which is not in the range of f is empty, that is,

$$\forall X, Y, f, y\,([f \in Y^X \,\wedge\, y \in Y] \Rightarrow [y \notin \mathrm{ran}(f) \Rightarrow f^{-1}[\{y\}] = \emptyset]). \tag{3.757}$$

(Hint: Prove the second implication by contraposition, using (2.42), (2.169) and the Double Negation Law.)

Exercise 3.94. Show for any sets X, Y and any surjection $f : X \twoheadrightarrow Y$ that the inverse image (under f) of any nonempty subset of Y is nonempty, i.e.

$$\forall X, Y, f\,(f : X \twoheadrightarrow Y \;\Rightarrow \forall C\,([C \subseteq Y \,\wedge\, C \neq \emptyset] \Rightarrow f^{-1}[C] \neq \emptyset)). \quad (3.758)$$

(Hint: Proceed similarly as in the proof of Proposition 3.226, using (2.42).)

Proposition 3.227. *For any function $f : X \to Y$ the inverse image of the complement (with respect to the codomain) of a subset B of Y equals the complement (with respect to the domain) of the inverse image of B, that is,*

$$\forall B\,(B \subseteq Y \Rightarrow f^{-1}[B^c] = (f^{-1}[B])^c). \quad (3.759)$$

Proof. We let X, Y, f and B be arbitrary sets, assume $f : X \to Y$, and assume furthermore that B is a subset of Y. Letting x also be arbitrary, we now obtain the true equivalences

$$\begin{aligned} x \in f^{-1}[B^c] &\Leftrightarrow f(x) \in B^c \\ &\Leftrightarrow f(x) \in Y \setminus B \\ &\Leftrightarrow f(x) \in Y \,\wedge\, \neg f(x) \in B \\ &\Leftrightarrow x \in f^{-1}[Y] \,\wedge\, \neg x \in f^{-1}[B] \\ &\Leftrightarrow x \in f^{-1}[Y] \setminus f^{-1}[B] \\ &\Leftrightarrow x \in X \setminus f^{-1}[B] \\ &\Leftrightarrow x \in (f^{-1}[B])^c \end{aligned}$$

using (3.742), the definition of a complement (applied with respect to Y), the definition of a set difference, again (3.742), again the definition of a set difference, then (3.746), and finally the definition of a complement (applied now with respect to X). Because x is arbitrary, we may therefore conclude that the equivalence

$$x \in f^{-1}[B^c] \Leftrightarrow x \in (f^{-1}[B])^c$$

holds for all x, so that $f^{-1}[B^c] = (f^{-1}[B])^c$ follows to be true with the Equality Criterion for sets. Since X, Y, f and B were arbitrary, we may then further conclude that the proposition holds, as claimed. □

Exercise 3.95. Verify for any function $f : X \to Y$ and any subsets A, B of Y that

a) the inverse image of the intersection of A and B is identical with the intersection of the inverse image of A and the inverse image of B, i.e.

$$\forall X, Y, f, A, B\,([f \in Y^X \;\wedge\; A \subseteq Y \;\wedge\; B \subseteq Y] \\ \Rightarrow\; f^{-1}[A \cap B] = f^{-1}[A] \cap f^{-1}[B]). \tag{3.760}$$

b) the inverse image of the union of A and B is identical with the union of the inverse image of A and the inverse image of B, i.e.

$$\forall X, Y, f, A, B\,([f \in Y^X \;\wedge\; A \subseteq Y \;\wedge\; B \subseteq Y] \\ \Rightarrow\; f^{-1}[A \cup B] = f^{-1}[A] \cup f^{-1}[B]). \tag{3.761}$$

(Hint: Proceed similarly as in the proof of Proposition 3.227.)

Exercise 3.96. Show for any functions $f : X \to Y$, $g : Y \to Z$ and any subset $B \subseteq Z$ that the inverse image of B under the composition of g and f is identical with the inverse image (under f) of the inverse image (under g) of B, that is,

$$\forall X, Y, Z, f, g, B\,([f \in Y^X \;\wedge\; g \in Z^Y \;\wedge\; B \subseteq Z] \\ \Rightarrow\; (g \circ f)^{-1}[B] = f^{-1}[g^{-1}[B]]). \tag{3.762}$$

(Hint: Apply Notation 3.6.)

Theorem 3.228. *For any function $f : X \to Y$ there is a unique function $f^{\leftarrow}$ from $\mathcal{P}(Y)$ to $\mathcal{P}(X)$ such that any $B \subseteq Y$ is mapped to the preimage of B under f.*

Proof. Letting X, Y and f be arbitrary sets such that $f : X \to Y$, we may apply the Axiom of Specification in connection with the Equality Criterion for sets to establish the true uniquely existential sentence

$$\exists! f^{\leftarrow}\, \forall Z\,(Z \in f^{\leftarrow} \Leftrightarrow [Z \in \mathcal{P}(Y) \times \mathcal{P}(X) \wedge \exists B\,(B \subseteq Y \wedge Z = (B, f^{-1}[B]))]).$$

We thus specified the set $f^{\leftarrow}$ such that it satisfies

$$\forall Z\,(Z \in f^{\leftarrow} \Leftrightarrow [Z \in \mathcal{P}(Y) \times \mathcal{P}(X) \;\wedge\; \exists B\,(B \subseteq Y \;\wedge\; Z = (B, f^{-1}[B]))]). \tag{3.763}$$

Clearly, $Z \in f^{\leftarrow}$ implies in particular $Z \in \mathcal{P}(Y) \times \mathcal{P}(X)$ for any Z, so that the inclusion $f^{\leftarrow} \subseteq \mathcal{P}(Y) \times \mathcal{P}(X)$ holds by definition of a subset. We may therefore apply the Function Criterion to prove that the binary relation $f^{\leftarrow}$ is a function from $\mathcal{P}(Y)$ to $\mathcal{P}(X)$. To do this, we verify

$$\forall B\,(B \in \mathcal{P}(Y) \Rightarrow \exists! A\,(A \in \mathcal{P}(X) \;\wedge\; (B, A) \in f^{\leftarrow})). \tag{3.764}$$

Letting $\bar{B}$ be arbitrary in $\mathcal{P}(Y)$, so that $\bar{B} \subseteq Y$ holds by definition of a power set, it follows that the inverse image $f^{-1}[\bar{B}]$ is a uniquely specified set according to Theorem 3.222a). Then, the ordered pair $\bar{Z} = (\bar{B}, f^{-1}[\bar{B}])$ is also uniquely determined. Together with $\bar{B} \subseteq Y$, this equation shows that there exists a set B such that the conjunction $B \subseteq Y \wedge Z = (B, f^{-1}[B])$ holds. Let us now observe that the inverse image $f^{-1}[\bar{B}]$ is a subset of X according to Note 3.30, and thus an element of the power set $\mathcal{P}(X)$. Thus, the conjunction $\bar{B} \in \mathcal{P}(Y) \wedge f^{-1}[\bar{B}] \in \mathcal{P}(X)$ is true, which implies $(\bar{B}, f^{-1}[\bar{B}]) \in \mathcal{P}(Y) \times \mathcal{P}(X)$ with the definition of the Cartesian product of two sets. Together with the previously established existential sentence with respect to B, this implies with (3.763) that $(\bar{B}, f^{-1}[\bar{B}]) \in f^{\leftarrow}$ holds. Together with the previously obtained $f^{-1}[\bar{B}] \in \mathcal{P}(X)$, this finding proves the existential part of the uniquely existential sentence in (3.764). Regarding the uniqueness part, we take arbitrary sets A and A', assume $A, A' \in \mathcal{P}(X)$ as well as $(\bar{B}, A), (\bar{B}, A') \in f^{\leftarrow}$ to be true, and show that these assumptions imply $A = A'$. Here, the latter assumption implies with (3.763) in particular that there are sets, say $\bar{\bar{B}}$ and $\bar{\bar{B}}'$, satisfying in particular $(\bar{B}, A) = (\bar{\bar{B}}, f^{-1}[\bar{\bar{B}}])$ and $(\bar{B}, A') = (\bar{\bar{B}}', f^{-1}[\bar{\bar{B}}'])$. These equations give now with the Equality Criterion for ordered pairs $\bar{B} = \bar{\bar{B}}$ and $A = f^{-1}[\bar{\bar{B}}]$, as well as $\bar{B} = \bar{\bar{B}}'$ and $A' = f^{-1}[\bar{\bar{B}}']$. We therefore obtain with the uniqueness of an inverse image

$$A = f^{-1}[\bar{\bar{B}}] = f^{-1}[\bar{B}] = f^{-1}[\bar{\bar{B}}'] = A',$$

which equations yield the desired $A = A'$. This completes the proof of the uniqueness part, and thus the proof of the uniquely existential sentence in (3.764). Since $\bar{B}$ is arbitrary, we may now further conclude that the universal sentence (3.764) holds, which in turn implies $f^{\leftarrow} : \mathcal{P}(Y) \to \mathcal{P}(X)$ (with the Function Criterion). This follows then to be true for any X, Y and f. □

Definition 3.56 (Inverse-image function, preimage function). For any function $f : X \to Y$ we call the function

$$f^{\leftarrow} : \mathcal{P}(Y) \to \mathcal{P}(X), \quad B \mapsto f^{\leftarrow}(B) = f^{-1}[B], \tag{3.765}$$

which maps every subset of Y into the inverse image of B under f, the *inverse-image function* or the *preimage function* of f.

The preimage function of a constant function has a particularly simple form.

Proposition 3.229. *The preimage function of any constant function g_c : $X \to Y$ consists of the domain of f and the empty set, that is,*

$$\forall X, Y, c, g_c \, (g_c : X \to Y \ \Rightarrow \operatorname{ran}(g_c^{\leftarrow}) = \{X, \emptyset\}). \tag{3.766}$$

Proof. We let X, Y, c and g_c be arbitrary and assume that g_c is the constant function $g_c : X \to Y$ with value c. To prove the equation in (3.766), we apply the Equality Criterion for sets and verify the equivalent universal sentence

$$\forall A\,(A \in \operatorname{ran}(g_c^{\leftarrow}) \Leftrightarrow A \in \{\emptyset, X\}). \tag{3.767}$$

For this purpose, we let $\bar{A}$ be an arbitrary set and assume first $A \in \operatorname{ran}(g_c^{\leftarrow})$. By definition of a range, there then exists a set, say $\bar{B}$, such that $(\bar{B}, \bar{A}) \in g_c^{\leftarrow}$ holds. We therefore obtain with the definition of a preimage function

$$\bar{A} = g_c^{\leftarrow}(\bar{B}) = g_c^{-1}[\bar{B}],$$

where $g_c^{-1}[\bar{B}] = X$ or $g_c^{-1}[\bar{B}] = \emptyset$ holds due to Proposition 3.225. Then substitution yields the true disjunction $\bar{A} = X \vee \bar{A} = \emptyset$, so that $\bar{A} \in \{X, \emptyset\}$ follows to be true with the definition of a pair, proving the first part ('$\Rightarrow$') of the equivalence in (3.767). Regarding the second part ('$\Leftarrow$'), we now assume $\bar{A} \in \{X, \emptyset\}$ to be true, so that $\bar{A} = X \vee \bar{A} = \emptyset$ holds (by definition of a pair). On the one hand, if the first part $\bar{A} = X$ of this disjunction is true, then we obtain

$$g_c^{\leftarrow}(Y) = g_c^{-1}[Y] = X\ [= \bar{A}]$$

with the definition of a preimage function (using the fact that Y is evidently element of the domain $\mathcal{P}(Y)$ of $g_c^{\leftarrow}$) and with Exercise 3.90b), which we may also write as $(Y, \bar{A}) \in g_c^{\leftarrow}$. Consequently, $\bar{A} \in \operatorname{ran}(g_c^{\leftarrow})$ follows to be true by definition of a range. On the other hand, if $\bar{A} = \emptyset$ is true, then we obtain

$$g_c^{\leftarrow}(\emptyset) = g_c^{-1}[\emptyset] = \emptyset\ [= \bar{A}]$$

by applying again with the definition of a preimage function (using now the fact that $\emptyset$ is clearly element of the domain $\mathcal{P}(Y)$ of $g_c^{\leftarrow}$) and by applying Exercise 3.90a). We may now write this as $(\emptyset, \bar{A}) \in g_c^{\leftarrow}$, and therefore $\bar{A} \in \operatorname{ran}(g_c^{\leftarrow})$ follows again to be true with the definition of a range. This completes the proof of the equivalence in (3.767), and since $\bar{A}$ is arbitrary, we may infer from this the truth of the universal sentence (3.767), and thus the truth of the desired equation $\operatorname{ran}(g_c^{\leftarrow}) = \{X, \emptyset\}$. This in turn proves the implication in (3.767), and as X, Y, c and g_c were arbitrary, we may then finally conclude that the proposition is true. □

3.4.6. Families

The concept of a functions may be applied to list constants according to a specified index (set).

Notation 3.7 (Family, term, index set, index). For any function $f : I \to Y$ we also write

$$(f_i)_{i\in I} \quad \text{or} \quad (f_i \mid i \in I) \tag{3.768}$$

and speak of a *family* in Y, and we call

$$f_i = f(i) \tag{3.769}$$

for every $i \in I$ a *term* of the family. Then, for any family $(f_i)_{i\in I}$, we call I the *index set* and each $i \in I$ an *index* of the family.

Theorem 3.230 (Criterion for lower & upper bounds for a family). *It is true for any family $f = (f_i)_{i\in I}$ in any set in Y and for any partial ordering $\leq_Y$ of Y that*

a) an element $a \in Y$ is a lower bound for f iff

$$\forall i\,(i \in I \Rightarrow a \leq_Y f_i). \tag{3.770}$$

b) an element $u \in Y$ is an upper bound for f iff

$$\forall i\,(i \in I \Rightarrow f_i \leq_Y u). \tag{3.771}$$

Proof. We let Y be an arbitrary set, $\leq_Y$ an arbitrary reflexive partial ordering of Y, and $f = (f_i)_{i\in I}$ an arbitrary family in Y. Concerning a), we let a be an arbitrary element of Y. To prove the first part ('$\Rightarrow$') of the equivalence, we assume that a is a lower bound for f, which means by definition that a is a lower bound for the range of f. We now let $i \in I$ be arbitrary, so that i is an element of the domain I of f. By definition, there exists then a particular constant $\bar{y}$ such that $(i, \bar{y}) \in f$. We can write the latter also as $\bar{y} = f(i) = f_i$ by using the notations for functions and families. Furthermore, $(i, \bar{y}) \in f$ implies $\bar{y} \in \mathrm{ran}(f)$ with the definition of a range. Since a is a lower bound for that range, it is by definition true that $a \leq_Y \bar{y}$ $[= f_i]$. We thus have $a \leq_Y f_i$, and as i was arbitrary, we may therefore conclude that the universal sentence (3.770) is true, so that the proof of the first part of the equivalence is complete.

To establish the second part ('$\Leftarrow$'), we assume now (3.770) to be true, and we show that a is a lower bound $\mathrm{ran}(f)$. Letting $y \in \mathrm{ran}(f)$ be arbitrary, there evidently exists a particular index $j \in I$ with $(j, y) \in f$, that is, with $y = f_j$. Consequently, $j \in \mathrm{dom}(f)$ $[= I]$ is clearly true, so that

$a \leq_Y f_j$ holds according to (3.770); thus, $a \leq y$. As y was arbitrary, we may therefore conclude that a is a lower bound for $\mathrm{ran}(f)$, completing the proof of the equivalence.

Since a, Y, $\leq_Y$ and $f = (f_i)_{i \in I}$ were initially arbitrary as well, we may further conclude that a) holds. Sentence b) can be proved similarly. □

Exercise 3.97. Prove Part b) of Theorem 3.230.

We now consider the following, often occurring special cases of a family.

Proposition 3.231. *Verify for any sets I, X, Y and for any family $f = (f_i)_{i \in I}$ in Y^X that the family $f^{(x)} = (f_i(x))_{i \in I}$ exists uniquely in Y for any $x \in X$.*

Proof. We let I, X, Y, f and x be arbitrary, assume $f = (f_i)_{i \in I}$ to be a family in Y^X, and assume moreover $x \in X$ to be true. We now apply Function definition by replacement to prove that there exists a unique function $f^{(x)}$ with domain I such that

$$\forall i \, (i \in I \Rightarrow f^{(x)}(i) = f_i(x)) \tag{3.772}$$

holds. For this purpose, we verify

$$\forall i \, (i \in I \Rightarrow \exists! y \, (y = f_i(x))), \tag{3.773}$$

letting i be arbitrary and assuming $i \in I$ to be true. Therefore, there exists the unique term f_i (in Y^X) of the family $f = (f_i)_{i \in I}$, according to the Function Criterion, and this term is a function from X to Y. Then, the initial assumption $x \in X$ implies the existence of the unique function value $f_i(x)$ (in Y), again by virtue of the Function Criterion. Thus, $f_i(x)$ is a constant in Y, so that we obtain the true existential sentence $\exists! y \, (y = f_i(x))$ with (1.109). As i was arbitrary, we may therefore conclude that the universal sentence (3.773) is true, which in turn implies the unique existence of a function $f^{(x)}$ with domain I satisfying (3.772). Thus, $f^{(x)}$ is a family with index set I, which we may write as $f^{(x)} = (f_i(x))_{i \in I}$. We now show that Y is a codomain of this family, i.e. that $\mathrm{ran}(f^{(x)}) \subseteq Y$ holds. To do this, we verify

$$\forall y \, (y \in \mathrm{ran}(f^{(x)}) \Rightarrow y \in Y), \tag{3.774}$$

letting y be arbitrary and assuming $y \in \mathrm{ran}(f^{(x)})$ to hold. By definition of a range, there exists then a constant, say $\bar{k}$, with $(\bar{k}, y) \in f^{(x)}$, which we may write in function/family notation as $y = f^{(x)}(\bar{k}) = f_{\bar{k}}(x)$. We may write now the resulting equation $y = f_{\bar{k}}(x)$ also as $(x, y) \in f_{\bar{k}}$, which shows that y is an element of the range of the function $f_{\bar{k}} : X \to Y$. Here, $\mathrm{ran}(f_{\bar{k}}) \subseteq Y$ holds by definition of a codomain, so that $y \in \mathrm{ran}(f_{\bar{k}})$ gives $y \in Y$ with the definition of a subset. This finding completes the proof of the implication in (3.774), and since y is arbitrary, we may therefore conclude that (3.774) holds, which universal sentence yields $\mathrm{ran}(f^{(x)}) \subseteq Y$ (by definition of a subset). Thus, Y is a codomain of $f^{(x)}$, so that the latter is a family in Y.

Because I, X, Y, f and x were initially arbitrary, we may infer from these findings the truth of the proposed sentence. □

Note 3.32. We call a family $f = (f_i)_{i\in I}$ in a set Y^X also a *family of functions* (from X to Y).

Definition 3.57 (Sequence, family & sequence of sets). We say that a family $(f_i)_{i\in I}$

(1) is a *sequence* if

- $I = n$ for some $n \in \mathbb{N}$, or
- $I = \mathbb{N}$, in which case we write the family also as

$$(f_n)_{n\in\mathbb{N}}, \tag{3.775}$$

or

- $I = \mathbb{N}_+$, in which case we write

$$(f_n)_{n\in\mathbb{N}_+}. \tag{3.776}$$

(2) is a *family of sets* iff it is a family in some set system.

(3) is a *sequence of sets* iff it is a sequence in some set system.

Note 3.33. In Chapter 4, we will introduce sequences with index sets different from those considered in Definition 3.57(1). Therefore, the current definition of a sequence is not bidirectional, as indicated by the one-directional 'if'.

Proposition 3.232. *For any set system $\mathcal{K}$ there is a family $(A_i)_{i\in I}$ with range $\mathcal{K}$, i.e.*

$$\forall \mathcal{K}\, \exists I, A\, (A = (A_i)_{i\in I} \wedge \mathrm{ran}(A) = \mathcal{K}). \tag{3.777}$$

Proof. We let $\mathcal{K}$ be an arbitrary set system, define $I = \mathcal{K}$, and let $A = \mathrm{id}_{\mathcal{K}}$ be the identity function on $\mathcal{K}$. Thus, we may write A as $A : \mathcal{K} \to \mathcal{K}$, or equivalently as $A : I \to \mathcal{K}$, and therefore as $(A_i)_{i\in I}$ (by definition of a family). The identity function $A : \mathcal{K} \to \mathcal{K}$ is a bijection (see Corollary 3.203), thus in particular a surjection (by Property 2 of a bijection), which implies $\mathrm{ran}(A) = \mathcal{K}$ with the definition of a surjection. Therefore, the existential sentence in (3.777) holds for an arbitrary $\mathcal{K}$, so that we may conclude that the universal sentence (3.777) is true. □

Definition 3.58 (Union & intersection of a family of sets). For any family of sets $A = (A_i \mid i \in I)$

a) we call the set

$$\bigcup_{i \in I} A_i = \bigcup \operatorname{ran}(A) \tag{3.778}$$

the *union of* A, and

b) with $I \neq \emptyset$ we call the set

$$\bigcap_{i \in I} A_i = \bigcap \operatorname{ran}(A) \tag{3.779}$$

the *intersection of* A.

Note 3.34. Since $[\operatorname{dom}(A) =]\ I \neq \emptyset$ implies $\operatorname{ran}(A) \neq \emptyset$ due to Exercise 3.19 in connection with the Law of Contraposition, the intersection (3.779) is then indeed specified.

We will use a slightly different notation for such unions and intersections in the case that the family is a sequence of sets with domain $\mathbb{N}$ or $\mathbb{N}_+$.

Notation 3.8. We will write for the *union of a sequence of sets* $A = (A_n)_{n \in \mathbb{N}}$ and $A = (A_n)_{n \in \mathbb{N}_+}$, respectively,

$$\bigcup_{n=0}^{\infty} A_n, \tag{3.780}$$

$$\bigcup_{n=1}^{\infty} A_n. \tag{3.781}$$

Similarly, we write for the *intersection of a sequence of sets* $A = (A_n)_{n \in \mathbb{N}}$ and $A = (A_n)_{n \in \mathbb{N}_+}$, respectively,

$$\bigcap_{n=0}^{\infty} A_n, \tag{3.782}$$

$$\bigcap_{n=1}^{\infty} A_n. \tag{3.783}$$

Based on the family notation, we may now replace the characteristic properties (2.197) and (2.89) of the union and intersection of an arbitrary set system by the following equivalent, easier-to-handle properties.

Theorem 3.233 (Characterization of the union & the intersection of a family of sets). *For any family of sets* $A = (A_i)_{i \in I}$, *a) it is true that an element y is in the union of the family A iff y is in A_i for some index i in I, i.e.*

$$\forall y\,(y \in \bigcup_{i\in I} A_i \Leftrightarrow \exists i\,(i \in I \,\wedge\, y \in A_i)). \tag{3.784}$$

b) with $I \neq \emptyset$ it is true that an y is in the intersection of the family A iff y is in A_i for all indexes i in I, i.e.

$$\forall y\,(y \in \bigcap_{i\in I} A_i \Leftrightarrow \forall i\,(i \in I \,\Rightarrow\, y \in A_i)). \tag{3.785}$$

Proof. We let A and I be arbitrary sets and assume that A is a family of sets with index set I, so that $A = (A_i)_{i\in I}$ is a function with domain I.

Concerning a), we take an arbitrary y and prove the first implication ('⇒') directly, assuming $y \in \bigcup_{i\in I} A_i$ to be true. Thus, $y \in \bigcup \mathrm{ran}(A)$ holds by definition of the union of a family of sets, which in turn implies

$$\exists Y\,(Y \in \mathrm{ran}(A) \,\wedge\, y \in Y)$$

with the definition of the union of a set system. Thus, there exists a set, say $\bar{Y}$, satisfying the conjunction of $\bar{Y} \in \mathrm{ran}(A)$ and $y \in \bar{Y}$. Here, the first part of the conjunction implies by definition of a range that there is an element, say $\bar{i}$, such that $(\bar{i}, \bar{Y}) \in A$ holds; since A was assumed to be a function, we may write this also as $\bar{Y} = A(\bar{i}) = A_{\bar{i}}$. Then, the second part $y \in \bar{Y}$ of the preceding conjunction yields via substitution $y \in A_{\bar{i}}$. Moreover, since I was assumed to be the domain of A, it follows from $(\bar{i}, \bar{Y}) \in A$ that $\bar{i} \in I$ holds. We thus showed that there is some i such that $i \in I$ and $y \in A_i$ are both true, which existential sentence proves the first part of the equivalence in (3.784).

To prove the second implication ('⇐') directly, we now assume that there exists an element, say $\bar{i}$, such that $\bar{i} \in I$ and $y \in A_{\bar{i}}$ are true. Here $\bar{i} \in I$ [$=$ $\mathrm{dom}(A)$] implies by definition of a domain that there exists a set, say $\bar{Y}$, with $(\bar{i}, \bar{Y}) \in A$, which we may also write as $\bar{Y} = A(\bar{i}) = A_{\bar{i}}$; with these equations, $y \in A_{\bar{i}}$ gives $y \in \bar{Y}$. Furthermore, it follows from $(\bar{i}, \bar{Y}) \in A$ with the definition of a range that $\bar{Y} \in \mathrm{ran}(A)$ holds. We thus established the existence of a set Y which satisfies both $Y \in \mathrm{ran}(A)$ and $y \in Y$. This existential sentence then further implies $y \in \bigcup \mathrm{ran}(A)$ by definition of the union of a set system, which yields $y \in \bigcup_{i\in I} A_i$ with the definition of the union of a family of sets. Thus, the proof of the equivalence in (3.784) is complete.

Since A and I were initially arbitrary, we may therefore conclude that a) holds for any set A and any set I. □

Exercise 3.98. Prove Part b) of Theorem 3.233.

Exercise 3.99. Prove that the union of any family of empty sets is empty, that is,

$$\forall I, A\,(A : I \to \{\emptyset\} \Rightarrow \bigcup_{i\in I} A_i = \emptyset). \tag{3.786}$$

Corollary 3.234. *The union of any set system $\mathcal{K}$ can be written as the union of a family of sets in $\mathcal{K}$, that is,*

$$\forall \mathcal{K}\, \exists I, A\,(A : I \to \mathcal{K} \,\wedge\, \bigcup \mathcal{K} = \bigcup_{i\in I} A_i). \tag{3.787}$$

Proof. Letting $\mathcal{K}$ be an arbitrary set system, there exist according to Proposition 3.232 sets, say $\bar{I}$ and $\bar{A}$, such that $\bar{A}$ is a family of sets $(A_i)_{i\in I}$ with $\mathrm{ran}(\bar{A}) = \mathcal{K}$. The latter equation then yields

$$\bigcup \mathcal{K} = \bigcup \mathrm{ran}(\bar{A}) = \bigcup_{i\in I} A_i$$

by applying substitution and the definition of the union of a family of sets, so that the existential sentence in (3.787) is evidently true. Since $\mathcal{K}$ was arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Exercise 3.100. Show that the intersection of any set system $\mathcal{K}$ can be written as the intersection of a family of sets in $\mathcal{K}$, that is,

$$\forall \mathcal{K}\, \exists I, A\,(A : I \to \mathcal{K} \,\wedge\, \bigcap \mathcal{K} = \bigcap_{i\in I} A_i). \tag{3.788}$$

Definition 3.59 (Family of pairwise disjoint sets, pairwise disjoint terms, partition). We say for any index set I, any set X and any system $\mathcal{K}$ of subsets of X that a family of sets $A : I \to \mathcal{K}$ is

(1) a *family of pairwise disjoint sets* in $\mathcal{K}$ (alternatively, that a family of sets $A : I \to \mathcal{K}$ has *pairwise disjoint terms*) iff the terms A_i and A_j are disjoint for any distinct indexes i and j, i.e. iff

$$\forall i, j\,([i, j \in I \,\wedge\, i \neq j] \Rightarrow A_i \cap A_j = \emptyset). \tag{3.789}$$

(2) a *partition* of X iff the terms of the family are pairwise disjoint and the union of the family is identical with X, that is, iff

$$\forall i, j\,([i, j \in I \,\wedge\, i \neq j] \Rightarrow A_i \cap A_j = \emptyset) \,\wedge\, \bigcup_{i\in I} A_i = X. \tag{3.790}$$

Proposition 3.235. *The following equation holds for any sequences of sets* $A = (A_n)_{n\in\mathbb{N}_+}$ *and* $B = (B_n)_{n\in\mathbb{N}_+}$.

$$\bigcup_{n=1}^{\infty}(A_n \cup B_n) = \left(\bigcup_{n=1}^{\infty} A_n\right) \cup \left(\bigcup_{n=1}^{\infty} B_n\right). \tag{3.791}$$

Proof. We let A and B be arbitrary sets such that $A = (A_n)_{n\in\mathbb{N}_+}$ and $B = (B_n)_{n\in\mathbb{N}_+}$ are families of sets. To prove the proposed equation, we apply the Equality Criterion for sets and verify

$$\forall y\,(y \in \bigcup_{n=1}^{\infty}(A_n \cup B_n) \Leftrightarrow y \in \left(\bigcup_{n=1}^{\infty} A_n\right) \cup \left(\bigcup_{n=1}^{\infty} B_n\right)), \tag{3.792}$$

letting y be arbitrary. Let us first observe the truth of the equivalence

$$y \in \bigcup_{n=1}^{\infty}(A_n \cup B_n) \;\Leftrightarrow\; \exists n\,(n \in \mathbb{N}_+ \;\wedge\; y \in A_n \cup B_n) \tag{3.793}$$

in view of (3.784) in connection with Notation 3.8, and then truth of the equivalences

$$\begin{aligned} & y \in \left(\bigcup_{n=1}^{\infty} A_n\right) \cup \left(\bigcup_{n=1}^{\infty} B_n\right) \\ & \Leftrightarrow\; y \in \bigcup_{n=1}^{\infty} A_n \;\vee\; y \in \bigcup_{n=1}^{\infty} B_n & (3.794)\\ & \Leftrightarrow\; \exists n\,(n \in \mathbb{N}_+ \;\wedge\; y \in A_n) \;\vee\; \exists n\,(n \in \mathbb{N}_+ \;\wedge\; y \in B_n) & (3.795)\\ & \Leftrightarrow\; \exists n\,([n \in \mathbb{N}_+ \;\wedge\; y \in A_n] \;\vee\; [n \in \mathbb{N}_+ \;\wedge\; y \in B_n]) & (3.796) \end{aligned}$$

in light of the definition of the union of two sets, the Characterization of the union of a family of sets (applied to the given sequences) and the Distributive Law for quantification (1.75). Now, to prove the first part ('$\Rightarrow$') of the equivalence in (3.792), we assume

$$y \in \bigcup_{n=1}^{\infty}(A_n \cup B_n) \tag{3.797}$$

to be true, which assumption implies with (3.793) that there exists a constant, say $\bar{n}$, such that the conjunction of $\bar{n} \in \mathbb{N}_+$ and $y \in A_{\bar{n}} \cup B_{\bar{n}}$ holds. Since the equivalences

$$\begin{aligned} \bar{n} \in \mathbb{N}_+ \;\wedge\; y \in A_{\bar{n}} \cup B_{\bar{n}} \;&\Leftrightarrow\; \bar{n} \in \mathbb{N}_+ \;\wedge\; [y \in A_{\bar{n}} \;\vee\; y \in A_{\bar{n}}] & (3.798)\\ &\Leftrightarrow\; [\bar{n} \in \mathbb{N}_+ \;\wedge\; y \in A_{\bar{n}}] \;\vee\; [\bar{n} \in \mathbb{N}_+ \;\wedge\; y \in B_{\bar{n}}] & (3.799) \end{aligned}$$

are true because of the definition of the union of two sets and the Distributive Law for sentences (1.44), we see that the latter disjunction follows to be true, so that the existential sentence in (3.796) holds. Because of the true equivalences (3.794) – (3.796),

$$y \in \left(\bigcup_{n=1}^{\infty} A_n \right) \cup \left(\bigcup_{n=1}^{\infty} B_n \right) \tag{3.800}$$

follows then also to be true, completing the proof of the first part of the equivalence in (3.792).

To prove the second part ('$\Leftarrow$'), we now assume that (3.800) is true, so that the true equivalences (3.794) – (3.796) imply the existence of a particular constant $\bar{n}$ which satisfies the disjunction in (3.799). Because of the equivalences (3.798) – (3.799), $\bar{n}$ therefore satisfies also the conjunction on the left-hand side of the equivalence (3.798), which shows that the existential sentence (3.793) holds, which in turn implies (3.797) with the true equivalence (3.793). Thus, the second part of the equivalence is true as well, and as y is arbitrary, we may therefore conclude that the universal sentence (3.792) is true. Then, the truth of the equation (3.791) follows with the Equality Criterion for sets, and since A and B were initially also arbitrary, we may finally conclude that the proposition holds, as claimed. □

Proposition 3.236. *For any set X and any family of sets $(A_i)_{i \in I}$ with $I \neq \emptyset$ there exists the unique family of sets $(X \cap A_i)_{i \in I}$.*

Proof. We let X, I and A be arbitrary sets and assume that $A = (A_i)_{i \in I}$ is a family of sets with nonempty index set I. We now apply Function definition by replacement to establish the stated families of sets. For this purpose, we first prove

$$\forall i \, (i \in I \Rightarrow \exists! Y \, (Y = X \cap A_i)), \tag{3.801}$$

letting i be arbitrary in I. Since A is a function from I to $\mathrm{ran}(A)$ (using Exercise 3.70a)), the function value $A_i = A(i)$ exists then uniquely according to the Function Criterion. Then, the intersection $X \cap A_i$ is also uniquely specified, so that the uniquely existential sentence in (3.801) follows to be true with (1.109). Since i is arbitrary, we may therefore conclude that the universal sentence (3.801) holds. Therefore, there exists a unique function F with domain I satisfying $F(i) = X \cap A_i$. Thus, F is a family of sets with index set I and terms $F_i = F(i)$, so that we may write $F = (X \cap A_i)_{i \in I}$. As X, I and A were initially arbitrary sets, we may therefore conclude that the proposition is true. □

Exercise 3.101. Verify the following sentences.

a) For any set X and any family of sets $(A_i)_{i\in I}$ there exists the unique family of sets $(X \cup A_i)_{i\in I}$.

b) For any set X and any family of sets $(A_i)_{i\in I}$ there exists the unique family of sets $(A_i \setminus X)_{i\in I}$.

c) For any set X and any family of sets $(A_i)_{i\in I}$ there exist the unique families of sets $(X \times A_i)_{i\in I}$ and $(A_i \times X)_{i\in I}$.

d) For any set Y and any family of sets $(A_i)_{i\in I}$ in $\mathcal{P}(Y)$ there exists the unique family of sets $(A_i^c)_{i\in I}$, where complementation is taken with respect to Y.

e) For any function $f : X \to Y$ and any family of sets $(B_i)_{i\in I}$ in $\mathcal{P}(Y)$ there exists the unique family of sets $(f^{-1}[B_i])_{i\in I}$.

Exercise 3.102. Show for any set X and any family $(A_i)_{i\in I}$ of pairwise disjoint sets with $I \neq \emptyset$ that $(X \cap A_i)_{i\in I}$ is also a family of pairwise disjoint sets.

(Hint: Use Proposition 3.236, (2.62), (2.72) and (2.58).)

Lemma 3.237. *For any sets $I \neq \emptyset$ and X, for any set system $\mathcal{K}$, and for any family $A = (A_i)_{i\in I}$ of sets such that for any index i there exists a set C in $\mathcal{K}$ whose intersection with X constitutes the i-th term of the family, in the sense that*

$$\forall i\,(i \in I \Rightarrow \exists C\,(C \in \mathcal{K} \wedge X \cap C = A_i)), \tag{3.802}$$

it is true that there exists a family $B = (B_i)_{i\in I}$ of sets in $\mathcal{K}$ such that

$$\forall i\,(i \in I \Rightarrow X \cap B_i = A_i). \tag{3.803}$$

Proof. We let $I \neq \emptyset$, X, $\mathcal{K}$ and A be arbitrary sets, assuming A to be a family $A = (A_i)_{i\in I}$ of sets and assuming (3.802) to hold. To begin with the construction, we apply Function definition by replacement to establish unique function K with domain I, i.e. a unique family $K = (K_n)_{i\in I}$, such that any term K_i contains all the sets $C \in \mathcal{K}$ for which $X \cap C = A_i$ holds. For this purpose, we prove

$$\forall i\,(i \in I \Rightarrow \exists! Y\,(\forall C\,(C \in Y \Leftrightarrow [C \in \mathcal{K} \wedge X \cap C = A_i]))). \tag{3.804}$$

We take an arbitrary index i and observe that the uniquely existential sentence can be established by means of the Axiom of Specification and the Equality Criterion for sets (in the usual way). Since i is arbitrary, we may infer from this the truth of the universal sentence (3.804), so that there exists indeed a unique function/family K with domain I such that

$$\forall i\,(i \in I \Rightarrow \forall C\,(C \in K_i \Leftrightarrow [C \in \mathcal{K} \wedge X \cap C = A_i])). \tag{3.805}$$

We may now prove by contradiction that the empty set is not element of the range of that sequence. To do this, we assume the negation $\neg\emptyset \notin \mathrm{ran}(K)$ to be true, so that the Double Negation Law gives the true sentence $\emptyset \in \mathrm{ran}(K)$. By definition of a range, there exists then a constant, say $\bar{k}$, with $(\bar{k}, \emptyset) \in K$. On the one hand, this gives $\bar{k} \in I$ [$= \mathrm{dom}(K)$] by definition of a domain. On the other hand, because we established K already as a function/family, we may write $\emptyset = K_{\bar{k}}$. Now, the former finding implies with (3.802) that there is a particular set $\bar{C} \in \mathcal{K}$ with $X \cap \bar{C} = A_{\bar{k}}$. We therefore obtain $\bar{C} \in K_{\bar{k}}$ with (3.805), so that $K_{\bar{k}}$ is clearly a nonempty set. We thus found $\emptyset \neq K_{\bar{k}}$ and $\emptyset = K_{\bar{k}}$ to be both true, which conjunction constitutes a contradiction, completing the proof of $\emptyset \notin \mathrm{ran}(K)$. This finding in turn implies with the Axiom of Choice that there exists a function, say $\bar{f}$, such that $\bar{f} : \mathrm{ran}(K) \to \bigcup \mathrm{ran}(K)$ and the universal sentence

$$\forall Y\,(Y \in \mathrm{ran}(K) \Rightarrow \bar{f}(Y) \in Y) \tag{3.806}$$

hold. Then, the composition of $\bar{f}$ and K yields the function/family $\bar{f} \circ K : I \to \bigcup \mathrm{ran}(K)$ according to (3.604), which we denote in family notation by $\bar{B} = (\bar{B}_i)_{i \in I} = \bar{f} \circ K$. Let us verify here that $\bigcup \mathrm{ran}(K)$ is included in the set system $\mathcal{K}$, i.e. $\bigcup \mathrm{ran}(K) \subseteq \mathcal{K}$ (which will imply that $\bar{f} \circ K$ is a family in $\mathcal{K}$). Letting C be arbitrary and assuming $C \in \bigcup \mathrm{ran}(K)$ to be true, there is then (by definition of the union of a set system) a particular set $\bar{Y} \in \mathrm{ran}(K)$ with $C \in \bar{Y}$. Therefore, there is (by definition of a range) a particular constant $\bar{k}$ with $(\bar{k}, \bar{Y}) \in K$, which we may write also as $\bar{Y} = K_{\bar{k}}$; thus, substitution yields $C \in K_{\bar{k}}$. Moreover, $(\bar{k}, \bar{Y}) \in K$ shows (in light of the definition of a domain) that $\bar{k} \in I$ [$= \mathrm{dom}(K)$] holds. This and $C \in K_{\bar{k}}$ implies then with (3.805) especially the truth of $C \in \mathcal{K}$. We thus demonstrated that $C \in \bigcup \mathrm{ran}(K)$ implies $C \in \mathcal{K}$, and since C was arbitrary, we may therefore infer from this implication that the inclusion $\bigcup \mathrm{ran}(K) \subseteq \mathcal{K}$ holds (by definition of a subset). Consequently, the function/family $\bar{B} : I \to \bigcup \mathrm{ran}(K)$ has also the codomain $\mathcal{K}$ according to (3.519), i.e. $\bar{B} : I \to \mathcal{K}$ is a family $(\bar{B}_i)_{i \in I}$ of sets in $\mathcal{K}$.

It thus remains for us to prove that the family $\bar{B} = (\bar{B}_i)_{i \in I}$ satisfies

$$\forall i\,(i \in I \Rightarrow X \cap \bar{B}_i = A_i). \tag{3.807}$$

We let i be arbitrary, assuming $i \in I$ to hold, so that the associated term of the family $\bar{B}$ is given by $\bar{B}_i = \bar{f}(K_i)$. Clearly, the term K_i of the family

K is in the range of that sequence, i.e. $K_i \in \operatorname{ran}(K)$, which in turn implies $\bar{f}(K_i) \in K_i$ with (3.806). In view of the preceding equation, we therefore have $\bar{B}_i \in K_i$, and this yields in particular $X \cap \bar{B}_i = A_i$ due to (3.805). Here, i was arbitrary, so that the universal sentence follows to be true.

Since I, X, $\mathcal{K}$ and A were initially arbitrary sets, we may therefore conclude that the stated lemma holds. □

Corollary 3.238. *For any sets $I \neq \emptyset$ and X, for any set system $\mathcal{K}$, and for any family $A = (A_i)_{i\in I}$ of sets such that for any index i there exists a set C in $\mathcal{K}$ whose intersection with X constitutes the i-th term of the family, in the sense that*

$$\forall i\,(i \in I \Rightarrow \exists C\,(C \in \mathcal{K} \wedge X \cap C = A_i)),$$

it is true that there exists a family of sets $(X \cap B_i)_{i\in I}$ such that

$$(A_i)_{i\in I} = (X \cap B_i)_{i\in I}. \tag{3.808}$$

Theorem 3.239 (Associative Laws for families of sets). *The following equations hold for any set X and any family of sets $(A_i)_{i\in I}$ with $I \neq \emptyset$.*

a) The intersection of the family of sets $(X \cap A_i)_{i\in I}$ is identical with the intersection of X and the family $(A_i)_{i\in I}$, i.e.

$$\bigcap_{i\in I}(X \cap A_i) = X \cap \bigcap_{i\in I} A_i. \tag{3.809}$$

b) The union of the family of sets $(X \cup A_i)_{i\in I}$ is identical with the union of X and the family $(A_i)_{i\in I}$, i.e.

$$\bigcup_{i\in I}(X \cup A_i) = X \cup \bigcup_{i\in I} A_i. \tag{3.810}$$

Proof. Concerning b), we let X, A and I be arbitrary sets, assume $I \neq \emptyset$, so that the existential sentence $\exists i\,(i \in I)$ is true according to 2.42, and assume moreover that $A = (A_i)_{i\in I}$ is a family of sets with index set I. Then, the family of sets $(X \cup A_i)_{i\in I}$ is uniquely specified according to Exercise 3.101a). Next, we apply the Equality Criterion for sets to prove the equation in (3.810) and verify accordingly

$$\forall y\,(y \in \bigcup_{i\in I}(X \cup A_i) \Leftrightarrow y \in X \cup \bigcup_{i\in I} A_i). \tag{3.811}$$

Letting y be arbitrary, we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming

$$y \in \bigcup_{i \in I} (X \cup A_i) \tag{3.812}$$

to be true, which then implies with the definition of the union of a family of sets

$$\exists i \, (i \in I \wedge y \in X \cup A_i). \tag{3.813}$$

Let us now observe the truth of the equivalences

$$y \in X \cup \bigcup_{i \in I} A_i \Leftrightarrow y \in X \vee \exists i \, (i \in I \wedge y \in A_i) \tag{3.814}$$

$$\Leftrightarrow [\exists i \, (i \in I) \wedge y \in X] \vee \exists i \, (i \in I \wedge y \in A_i) \tag{3.815}$$

$$\Leftrightarrow \exists i \, (i \in I \wedge y \in X) \vee \exists i \, (i \in I \wedge y \in A_i) \tag{3.816}$$

$$\Leftrightarrow \exists i \, ([i \in I \wedge y \in X] \vee [i \in I \wedge y \in A_i]) \tag{3.817}$$

using the definition of the union of two sets in connection with the definition of the union of a family of sets, then the fact that the previously established existential sentence $\exists i \, (i \in I)$ implies the equivalence of the sentence $y \in X$ and the conjunction $\exists i (i \in I) \wedge y \in X$ in view of (1.13), using subsequently (1.58), and using finally the Distributive Law for quantification (1.75). Therefore, to show that (3.813) implies the desired consequent $y \in X \cup \bigcup_{i \in I} A_i$, we may establish equivalently the right-hand side of (3.817), that is,

$$\exists i \, ([i \in I \wedge y \in X] \vee [i \in I \wedge y \in A_i]). \tag{3.818}$$

For this purpose, we notice in light of (3.813) that there is some index, say $\bar{i} \in I$, with $y \in X \cup A_{\bar{i}}$. Therefore, $y \in X \vee y \in A_{\bar{i}}$ holds by definition of the union of two sets. Thus, the conjunction

$$\bar{i} \in I \wedge [y \in X \vee y \in A_{\bar{i}}] \tag{3.819}$$

is true, which now further implies

$$[\bar{i} \in I \wedge y \in X] \vee [\bar{i} \in I \wedge y \in A_{\bar{i}}] \tag{3.820}$$

with the Distributive Law for sentences (1.44). The truth of this disjunction shows that the existential sentence (3.818) is indeed true. This finding implies in view of the true equivalences (3.814) – (3.817) that $y \in X \cup \bigcup_{i \in I} A_i$ holds, proving the first part of the equivalence in (3.811).

To prove the second part ('$\Leftarrow$'), we now assume $y \in X \cup \bigcup_{i \in I} A_i$ to be true, which then implies the truth of the existential sentence (3.818) with the true equivalences (3.814) – (3.817). We now show that (3.813) follows to be true. Because of (3.818), there is some index, say $\bar{i}$, such that (3.820) is true. This disjunction implies then (3.819) with the Distributive Law for sentences (1.44), and then also $\bar{i} \in I \wedge y \in X \cup A_{\bar{i}}$ (applying again the definition of the union of two sets). Thus, the existential sentence (3.813) holds, which in turn implies (3.812) by definition of the union of a family of sets, so that the proof of the second part of the equivalence in (3.811) is also complete.

As y was arbitrary, the universal sentence (3.811) follows then to be true, and this gives the proposed equation (3.810) with the Equality Criterion for sets. Since X, A and I were initially arbitrary sets, we may therefore conclude that the proposed universal sentence b) is true. $\square$

Exercise 3.103. Establish Part a) of Theorem 3.239.

(Hint: Proceed in analogy to the proof of Part b), replacing the two arguments to establish (3.815) and (3.816) by the single argument (1.58).)

Theorem 3.240 (Distributive Laws for families of sets). *The following equations hold for any set X and any family of sets $A = (A_i)_{i \in I}$ with $I \neq \emptyset$.*

a) The pairwise union is distributive with respect to the intersection of a family of sets in the sense that

$$X \cup \bigcap_{i \in I} A_i = \bigcap_{i \in I} (X \cup A_i). \tag{3.821}$$

b) The pairwise intersection is distributive with respect to the union of a family of sets in the sense that

$$X \cap \bigcup_{i \in I} A_i = \bigcup_{i \in I} (X \cap A_i). \tag{3.822}$$

c) The set difference is distributive with respect to the union of a family of sets in the sense that

$$\left(\bigcup_{i \in I} A_i \right) \setminus X = \bigcup_{i \in I} (A_i \setminus X). \tag{3.823}$$

d) The pairwise Cartesian product is distributive with respect to the union *of a family of sets in the sense that*

$$X \times \left(\bigcup_{i\in I} A_i\right) = \bigcup_{i\in I}(X \times A_i), \tag{3.824}$$

$$\left(\bigcup_{i\in I} A_i\right) \times X = \bigcup_{i\in I}(A_i \times X). \tag{3.825}$$

Proof. We let X, I and A be arbitrary sets, assume $I \neq \emptyset$, and assume further that $A = (A_i)_{i\in I}$ is a family of sets with index set I.

Concerning a), we prove the equation in (3.821) by means of the Equality Criterion for sets, i.e. by verifying

$$\forall y\,(y \in X \cup \bigcap_{i\in I} A_i \Leftrightarrow y \in \bigcap_{i\in I}[X \cup A_i]). \tag{3.826}$$

We let y be arbitrary, so that we obtain, on the one hand, the true equivalences

$$y \in X \cup \bigcap_{i\in I} A_i \Leftrightarrow [y \in X \lor \forall i\,(i \in I \Rightarrow y \in A_i)] \tag{3.827}$$

$$\Leftrightarrow \forall i\,(y \in X \lor [i \in I \Rightarrow y \in A_i]) \tag{3.828}$$

by applying the definition of the union of two sets together with the definition of the intersection of a family of sets and then the Neutrality Law for quantification (1.63). On the other hand, we obtain the true equivalence (applying again the definition of the intersection of a family of sets)

$$y \in \bigcap_{i\in I}[X \cup A_i] \;\Leftrightarrow\; \forall i\,(i \in I \Rightarrow y \in X \cup A_i). \tag{3.829}$$

Now, to prove the first part ('$\Rightarrow$') of the equivalence in (3.826), we assume that $y \in X \cup \bigcap_{i\in I} A_i$ is true, which implies the universal sentence

$$\forall i\,(y \in X \lor [i \in I \Rightarrow y \in A_i]) \tag{3.830}$$

with the equivalences (3.827) – (3.828), and we show that the universal sentence

$$\forall i\,(i \in I \Rightarrow y \in X \cup A_i) \tag{3.831}$$

follows to be true. Letting $\bar{i}$ be arbitrary, we now obtain the true equivalences

$$y \in X \lor [\bar{i} \in I \Rightarrow y \in A_{\bar{i}}] \Leftrightarrow y \in X \lor [\bar{i} \notin I \lor y \in A_{\bar{i}}] \tag{3.832}$$

$$\Leftrightarrow \bar{i} \notin I \lor [y \in X \lor y \in A_{\bar{i}}] \tag{3.833}$$

$$\Leftrightarrow \bar{i} \in I \Rightarrow [y \in X \cup A_{\bar{i}}] \tag{3.834}$$

using the Conditional Law (1.31), the Associative Law for the disjunction (1.40), and finally again the Conditional Law (1.31) together with the definition of the union of two sets. Since the disjunction $y \in X \vee [\bar{i} \in I \Rightarrow y \in A_{\bar{i}}]$ is true because of (3.830), the preceding equivalences yield the true implication $\bar{i} \in I \Rightarrow [y \in X \cup A_{\bar{i}}]$. As $\bar{i}$ was arbitrary, we may therefore conclude that the universal sentence (3.831) holds indeed, which implies then in turn $y \in \bigcap_{i \in I}[X \cup A_i]$ with the true equivalence (3.829). Thus, the proof of the first part of the equivalence in (3.826) is complete.

To prove the second part ('$\Leftarrow$'), we now assume $y \in \bigcap_{i \in I}[X \cup A_i]$ to be true, which implies then the truth of the universal sentence (3.831) because of (3.829). Let us now verify that the universal sentence (3.830) follows to be true. Letting $\bar{i}$ be arbitrary, the true universal sentence (3.831) gives the true implication $\bar{i} \in I \Rightarrow [y \in X \cup A_{\bar{i}}]$, which then implies the truth of the disjunction $y \in X \vee [\bar{i} \in I \Rightarrow y \in A_{\bar{i}}]$, because the equivalence (3.832) – (3.834) hold again for the arbitrarily selected $\bar{i}$. We may now infer from this finding the truth of the universal sentence (3.830), which then further implies $y \in X \cup \bigcap_{i \in I} A_i$ with the true equivalences (3.827) – (3.828). This completes the proof of the second part of the equivalence in (3.826), and as y was arbitrary, we may therefore conclude that the universal sentence (3.826) is true.

In view of the Equality Criterion for sets, this shows that the sets $X \cup \bigcap_{i \in I} A_i$ and $\bigcap_{i \in I}(X \cup A_i)$ are identical, so that the equation (3.821) holds. Since X, I and A were initially also arbitrary, we may then further conclude that the proposed sentence a) is true.

Part b) and c) can be proved similarly.

Concerning d), we we prove the equation (3.824) by means of the Equality Criterion for sets, i.e. by verifying

$$\forall y\,(y \in X \times \bigcup_{i \in I} A_i \Leftrightarrow y \in \bigcup_{i \in I}[X \times A_i]). \tag{3.835}$$

We let y be arbitrary, and assume first $y \in X \times \bigcup_{i \in I} A_i$ to be true. By definition of the Cartesian product of two sets, there are then particular constants $\bar{x} \in X$ and $\bar{a} \in \bigcup_{i \in I} A_i$ satisfying $(\bar{x}, \bar{a}) = y$. According to the Characterization of the union of a family of sets, there is then a particular index $\bar{k} \in I$ such that $\bar{a} \in A_{\bar{k}}$ holds. Consequently, the conjunction of $\bar{x} \in X$ and $\bar{a} \in A_{\bar{k}}$ is true, which in turn implies $(\bar{x}, \bar{a}) \in X \times A_{\bar{k}}$ (by definition of the Cartesian product of two sets). We therefore obtain $y \in X \times A_{\bar{k}}$ via substitution, where $X \times A_{\bar{k}}$ is (in view of $\bar{k} \in I$) a term of the family of sets $(X \times A_i)_{i \in I}$ established in Exercise 3.101c). We thus showed that there exists an index $i \in I$ such that $y \in X \times A_i$ holds, which existential sentence implies the desired consequent $y \in \bigcup_{i\in I}(X \times A_i)$ of the first part ('$\Rightarrow$') of the equivalence in (3.835) by means of the Characterization of the union of a family of sets.

To establish the second part ('$\Leftarrow$'), we assume now $y \in \bigcup_{i\in I}(X \times A_i)$ to be true, so that there evidently exists a particular index $\bar{k} \in I$ with $y \in X \times A_{\bar{k}}$. We therefore have $y = (\bar{x}, \bar{a})$ for some particular $\bar{x} \in X$ and $\bar{a} \in A_{\bar{k}}$. The latter shows that $\bar{a} \in A_i$ holds for some $i \in I$, so that $\bar{a} \in \bigcup_{i\in I} A_i$ follows to be true. The simultaneous truth of $\bar{x} \in X$ and $\bar{a} \in \bigcup_{i\in I} A_i$ gives then $(\bar{x}, \bar{a}) \in X \times \bigcup_{i\in I} A_i$ and thus $y \in X \times \bigcup_{i\in I} A_i$, as desired. Having completed the proof of the equivalence in (3.835), we may now infer from this the truth of the universal sentence (3.835), because y was arbitrary. Then, the equation (3.824) follows to be true with the Equality Criterion for sets.

The proof of the other equation (3.825) is based on the same arguments as the proof of (3.824).

Since X, I and A were initially arbitrary sets, we may therefore conclude that the stated theorem is true. □

Exercise 3.104. Prove parts b) – d) of Theorem 3.240.

(Hint: Proceed in analogy to the proof of Part a).)

Theorem 3.241 (De Morgan's Laws for the intersection & the union of a family of sets). *The following equations hold for any set Y and any family of sets $A = (A_i)_{i\in I}$ in $\mathcal{P}(Y)$ with $I \neq \emptyset$.*

a) **De Morgan's Law for the intersection of a family of sets:**

$$\left(\bigcap_{i\in I} A_i^c\right)^c = \bigcup_{i\in I} A_i. \tag{3.836}$$

b) **De Morgan's Law for the union of a family of sets:**

$$\left(\bigcup_{i\in I} A_i^c\right)^c = \bigcap_{i\in I} A_i. \tag{3.837}$$

Proof. We let Y, I and A be arbitrary sets, assume $I \neq \emptyset$, and assume moreover that $A = (A_i)_{i\in I}$ is a family of sets in $\mathcal{P}(Y)$. Then, the family of sets $(A_i^c)_{i\in I}$ is uniquely specified according to Exercise 3.101b).

Concerning a), we may establish the equation in (3.837) via the Equality Criterion for sets and verify for this purpose the universal sentence

$$\forall y \, (y \in \left(\bigcup_{i\in I} A_i^c\right)^c \Leftrightarrow y \in \bigcap_{i\in I} A_i). \tag{3.838}$$

Letting y be arbitrary, we may on the one hand observe the truth of the equivalences

$$y \in \left(\bigcup_{i\in I} A_i^c\right)^c \Leftrightarrow y \notin \bigcup_{i\in I} A_i^c \tag{3.839}$$

$$\Leftrightarrow \neg\exists i\,(i \in I \,\wedge\, y \in A_i^c) \tag{3.840}$$

$$\Leftrightarrow \forall i\,(i \in I \Rightarrow y \notin A_i^c) \tag{3.841}$$

in light of (2.132), the definition of the union of a family of sets and (1.81). On the other hand, the definition of the intersection of a family of sets yields the true equivalence

$$y \in \bigcap_{i\in I} A_i \;\Leftrightarrow\; \forall i\,(i \in I \Rightarrow y \in A_i). \tag{3.842}$$

We now establish the first part ('⇒') of the equivalence in (3.838), assuming $y \in \left(\bigcup_{i\in I} A_i^c\right)^c$ to be true, so that

$$\forall i\,(i \in I \Rightarrow y \notin A_i^c) \tag{3.843}$$

follows to be true with the equivalences (3.839) – (3.841). We now show that this implies

$$\forall i\,(i \in I \Rightarrow y \in A_i). \tag{3.844}$$

For this purpose, we let $\bar{i} \in I$ be arbitrary, which gives $y \notin A_{\bar{i}}^c$ with (3.843), therefore $y \in (A_{\bar{i}}^c)^c$ with (2.132), and consequently $y \in A_{\bar{i}}$ with (2.136), proving the implication in (3.844). As $\bar{i}$ is arbitrary, we may now conclude that (3.844) holds, which in turn implies $y \in \bigcap_{i\in I} A_i$ according to (3.842). This finding proves the first implication '⇒'.

To establish the second part ('⇐'), we now assume that $y \in \bigcap_{i\in I} A_i$ holds, so that (3.844) follows to be true with (3.842). We may now prove that the truth of this universal sentence implies the truth of (3.843). To do this, we take an arbitrary $\bar{i} \in I$, so that (3.844) yields $y \in A_{\bar{i}}$, which further implies $y \in (A_{\bar{i}}^c)^c$ with (2.136) and then also $y \notin A_{\bar{i}}^c$ with (2.132). This negation proves the implication in (3.843), and since $\bar{i}$ is arbitrary, we may therefore conclude that (3.843) holds. This universal sentence in turn implies $y \in \left(\bigcup_{i\in I} A_i^c\right)^c$ with the previously established equivalences (3.839) – (3.841), completing the proof of the second implication '⇐'. Thus, the equivalence in (3.838) holds, and because y is arbitrary, we may then further conclude that (3.838) is also true.

The truth of that universal sentence means according to the Equality Criterion for sets that $\left(\bigcup_{i\in I} A_i^c\right)^c$ and $\bigcap_{i\in I} A_i$ are identical, so that the proof of the equation (3.837) is complete. As Y, I and A were arbitrary sets, the sentence a) follows to be universally true. □

Exercise 3.105. Establish Theorem 3.241b).
(Hint: Proceed similarly as in the proof of Theorem 3.241a).)

We now return to the issue of inverse images and establish a few more laws in the specific context of families of sets.

Proposition 3.242. *For any function $f : X \to Y$ the inverse image of the union of a family $B = (B_i)_{i \in I}$ of subsets of Y equals the union of the inverse images of the terms of B, that is,*

$$\forall X, Y, f, I, B\,([f \in Y^X \,\wedge\, B \in \mathcal{P}(Y)^I] \Rightarrow f^{-1}[\bigcup_{i \in I} B_i] = \bigcup_{i \in I} f^{-1}[B_i]). \tag{3.845}$$

Proof. Letting X, Y, f, I and B be arbitrary sets, we assume $f \in Y^X$ and $B \in \mathcal{P}(Y)^I$ to be true, so that f is a function from X to Y and B a family $(B_i)_{i \in I}$ in $\mathcal{P}(Y)$ (i.e., of subsets of Y). Then, the family of set $(f^{-1}[B_i])_{i \in I}$ is uniquely specified according to Exercise 3.101c). Let us now apply the Equality Criterion for sets and prove the equation in (3.845) by verifying the equivalent

$$\forall x\,(x \in f^{-1}[\bigcup_{i \in I} B_i] \Leftrightarrow x \in \bigcup_{i \in I} f^{-1}[B_i]). \tag{3.846}$$

Letting x be arbitrary, we first assume

$$x \in f^{-1}[\bigcup_{i \in I} B_i], \tag{3.847}$$

which implies with the definition of an inverse image

$$f(x) \in \bigcup_{i \in I} B_i, \tag{3.848}$$

and then with the definition of the union of a family of sets

$$\exists i\,(i \in I \,\wedge\, f(x) \in B_i). \tag{3.849}$$

Thus, there exists an index, say $\bar{i}$, such that

$$\bar{i} \in I \wedge f(x) \in B_{\bar{i}} \tag{3.850}$$

holds. This conjunction further implies with the definition of an inverse image

$$\bar{i} \in I \wedge x \in f^{-1}[B_{\bar{i}}], \tag{3.851}$$

and this conjunction shows that the existential sentence

$$\exists i\,(i \in I \;\wedge\; x \in f^{-1}[B_i]) \tag{3.852}$$

holds, so that the desired consequent

$$x \in \bigcup_{i \in I} f^{-1}[B_i] \tag{3.853}$$

follows to be true by definition of the union of a family of sets. Conversely, we now assume (3.853) to be true, so that (3.852) holds by definition of the union of a family of sets. Thus, there is an index, say $\bar{i}$, satisfying (3.851), which gives (3.850) (with the definition of an inverse image), so that the existential sentence (3.849) holds as well. This implies then first (3.848) with the definition of the union of a family of sets, and subsequently the desired (3.847) with the definition of an inverse image. We thus proved the equivalence in (3.846), and since x is arbitrary, we may therefore conclude that the universal sentence (3.846) is true. This in turn implies the equation in (3.845) with the Equality Criterion for sets, and as X, Y, f, I and B were also arbitrary, we may finally conclude that the proposed universal sentence (3.845) holds. □

Exercise 3.106. Show for any function $f : X \to Y$ that the inverse image of the intersection of a family $B = (B_i)_{i \in I}$ of subsets of Y with nonempty index set is identical with the intersection of the inverse images of the terms of B, that is,

$$\forall X, Y, f, I, B\,([f \in Y^X \wedge I \neq \emptyset \wedge B \in \mathcal{P}(Y)^I] \Rightarrow f^{-1}[\bigcap_{i \in I} B_i] = \bigcap_{i \in I} f^{-1}[B_i]). \tag{3.854}$$

Corollary 3.243 (Inverse image of the union of a family of disjoint sets). *For any function $f : X \to Y$ the inverse image of the union of a family $B = (B_i)_{i \in I}$ of disjoint subsets of Y equals the union of the family of sets $(f^{-1}[B_i])_{i \in I}$, and the terms of this family are all disjoint, that is,*

$$\forall X, Y, f, I, B\,(\Big[f \in Y^X \wedge B \in \mathcal{P}(Y)^I \wedge \forall i, j\,([i, j \in I \wedge i \neq j] \Rightarrow B_i \cap B_j = \emptyset)\Big] \Rightarrow$$
$$\Big[f^{-1}[\bigcup_{i \in I} B_i] = \bigcup_{i \in I} f^{-1}[B_i] \wedge \forall i, j\,([i, j \in I \wedge i \neq j] \Rightarrow f^{-1}[B_i] \cap f^{-1}[B_j] = \emptyset)\Big]). \tag{3.855}$$

Proof. Letting X, Y, f, I and B be arbitrary such that f is a function from X to Y and such that $B = (B_i)_{i \in I}$ is a family of sets in $\mathcal{P}(Y)$ with disjoint terms, satisfying

$$\forall i, j\,([i, j \in I \;\wedge\; i \neq j] \Rightarrow B_i \cap B_j = \emptyset), \tag{3.856}$$

we obtain the equation in (3.855) with (3.845). To show that

$$\forall i,j\,([i,j\in I\;\wedge\; i\neq j]\Rightarrow f^{-1}[B_i]\cap f^{-1}[B_j]=\emptyset) \tag{3.857}$$

also holds, we let i and j be arbitrary and assume $i,j\in I\wedge i\neq j$ to be true, which implies $B_i\cap B_j=\emptyset$ with the assumed (3.856). We then obtain the equations

$$f^{-1}[B_i]\cap f^{-1}[B_j]=f^{-1}[B_i\cap B_j]=f^{-1}[\emptyset]=\emptyset$$

by applying Exercise 3.95a), then substitution based on the previously established equation $B_i\cap B_j=\emptyset$, and finally Exercise 3.90a). These equations give the desired consequent $f^{-1}[B_i]\cap f^{-1}[B_j]=\emptyset$, and since i and j were arbitrary, we may therefore conclude that the universal sentence (3.857) is indeed true. As X, Y, f, I and B were also arbitrary, we may then further conclude that the proposed universal sentence (3.855) also holds. □

We now generalize the concept of a Cartesian product from two sets to a family of sets.

Proposition 3.244. *For any set I and any family $s=(X_i)_{i\in I}$ of sets, it is true that there exists a unique set (system) $\bigtimes_{i\in I}X_i$ such that a set f is element of $\bigtimes_{i\in I}X_i$ iff f is a family (with index set I) in the union of the family $(X_i)_{i\in I}$ and if any term f_i is in X_i, i.e.*

$$\exists!\bigtimes_{i\in I}X_i\;\forall f\,(f\in\bigtimes_{i\in I}X_i\Leftrightarrow[f\in[\bigcup_{i\in I}X_i]^I\;\wedge\;\forall i\,(i\in I\Rightarrow f_i\in X_i)]).$$

Furthermore, the set $\bigtimes_{i\in I}X_i$ satisfies

$$\forall f\,(f\in\bigtimes_{i\in I}X_i\Leftrightarrow[f\text{ is a family with index set }I\;\wedge\;\forall i\,(i\in I\Rightarrow f_i\in X_i)]). \tag{3.858}$$

Proof. Letting I be an arbitrary (index) set and letting s an arbitrary set such that $s=(X_i)_{i\in I}$ is a family of sets, we may evidently apply the Axiom of Specification and the Equality Criterion for sets to establish the stated uniquely existential sentence. Thus, the set $\bigtimes_{i\in I}X_i$ satisfies

$$\forall f\,(f\in\bigtimes_{i\in I}X_i\Leftrightarrow[f\in[\bigcup_{i\in I}X_i]^I\;\wedge\;\forall i\,(i\in I\Rightarrow f_i\in X_i)]). \tag{3.859}$$

To establish (3.858), we take an arbitrary set f and assume first $f\in\bigtimes_{i\in I}X_i$ to be true. This assumption implies with (3.859) in particular

$f \in [\bigcup_{i\in I} X_i]^I$, so that f is a function from I to $\bigcup_{i\in I} X_i$. Thus, f is a family with index set I. As the preceding assumption implies in particular also the truth of the universal sentence $\forall i\,(i \in I \Rightarrow f_i \in X_i)$, the conjunction in (3.858) holds, so that the first part ('$\Rightarrow$') of the equivalence is true.

Regarding the second part ('$\Leftarrow$'), we now assume that f is a family with index set I and that

$$\forall i\,(i \in I \Rightarrow f_i \in X_i) \tag{3.860}$$

holds. Thus, the second part of the conjunction in (3.859) already holds, and we may prove that the first part $f \in [\bigcup_{i\in I} X_i]^I$ also holds. Since we assumed f to be a family with index set I, we have that I is the domain of f. Next, we demonstrate that $\bigcup_{i\in I} X_i$ is a codomain of f, i.e. that the range of f is included in $\bigcup_{i\in I} X_i$. To show this, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall y\,(y \in \mathrm{ran}(f) \Rightarrow y \in \bigcup_{i\in I} X_i). \tag{3.861}$$

We let $\bar{y}$ be arbitrary and assume $\bar{y} \in \mathrm{ran}(f)$, so that there exists by definition of a range a constant, say $\bar{k}$, with $(\bar{k}, \bar{y}) \in f$. Since f is a function/family, we may write this also as $\bar{y} = f_{\bar{k}}$. Furthermore, we obtain with the definition of a domain $\bar{k} \in I$ $[= \mathrm{dom}(f)]$, so that (3.860) gives $[\bar{y} =]\ f_{\bar{k}} \in X_i$. Thus, the existential sentence $\exists i\,(i \in I \wedge \bar{y} \in X_i)$ is true, which in turn implies $\bar{y} \in \bigcup_{i\in I} X_i$ with the Characterization of the union of a family of sets. This finding proves the implication in (3.861), and as $\bar{y}$ was arbitrary, we may therefore conclude that (3.861) holds, which then yields $\mathrm{ran}(f) \subseteq \bigcup_{i\in I} X_i$ (by definition of a subset). Thus, $\bigcup_{i\in I} X_i$ is a codomain of f by definition, so that f is a function from I to $\bigcup_{i\in I} X_i$, and therefore an element of $[\bigcup_{i\in I} X_i]^I$. This completes the proof of the conjunction in (3.859), which in turn implies $f \in \bigtimes_{i\in I} X_i$, completing the proof of the equivalence in (3.858).

Because f is arbitrary, we may now further conclude that $\bigtimes_{i\in I} X_i$ satisfies indeed the universal sentence (3.858). Since I and X were initially arbitrary sets, we may finally infer from this the truth of the proposition. □

Definition 3.60 (Cartesian product of a family of sets). For any set I and any family $(X_i)_{i\in I}$ of sets, we call the unique set system

$$\bigtimes_{i\in I} X_i \tag{3.862}$$

consisting precisely of all families f with index set I and with i-th term f_i in X_i for all $i \in I$ the *Cartesian product* of $(X_i)_{i\in I}$.

Exercise 3.107. Show for any set I and any family $(X_i)_{i\in I}$ of sets that the Cartesian product of that family is identical with the singleton formed by the empty set if I is empty, that is,

$$I = \emptyset \;\Rightarrow\; \bigtimes_{i\in I} X_i = \{\emptyset\}. \tag{3.863}$$

(Hint: Apply the Equality Criterion for sets in connection with (3.858), (3.120) and (2.169).)

Notation 3.9. In the special cases of a sequence of sets $(X_n)_{n\in\mathbb{N}}$ and of a sequence of sets $(X_n)_{n\in\mathbb{N}_+}$, we also write, respectively,

$$\bigtimes_{n=0}^{\infty} X_n \quad \text{or} \quad X_0 \times X_1 \times \ldots \tag{3.864}$$

$$\bigtimes_{n=1}^{\infty} X_n \quad \text{or} \quad X_1 \times X_2 \times \ldots \tag{3.865}$$

Furthermore, if a sequence $(X_n)_{n\in\mathbb{N}_+}$ is constant in the sense that $X_n = X$ holds for any $n \in \mathbb{N}_+$, we write:

$$X^\omega \tag{3.866}$$

Theorem 3.245 (Emptiness Criterion for Cartesian products of families of sets). *It is true for any nonempty set I and any family $X = (X_i)_{i\in I}$ of sets that the Cartesian product of X is empty iff at least one of the terms of the family is nonempty, that is,*

$$\exists i\,(i \in I \,\wedge\, X_i = \emptyset) \;\Leftrightarrow\; \bigtimes_{i\in I} X_i = \emptyset. \tag{3.867}$$

Proof. We let I and X be arbitrary sets and assume that X is a family of sets with index set $I \neq \emptyset$, which family we may therefore write as $(X_i)_{i\in I}$. We prove the first part ('$\Rightarrow$') of the stated equivalence by contraposition, by assuming $\bigtimes_{i\in I} X_i \neq \emptyset$ and demonstrating the truth of the negated existential sentence in (3.867). Because of the Negation Law for existential conjunctions, we may prove equivalently the universal sentence

$$\forall i\,(i \in I \Rightarrow X_i = \emptyset), \tag{3.868}$$

letting $\bar{i}$ be arbitrary and assuming $\bar{i} \in I$ to be true. The preceding assumption $\bigtimes_{i\in I} X_i \neq \emptyset$ implies with (2.42) that there exists an element in the Cartesian product $\bigtimes_{i\in I} X_i$, say $\bar{f}$. It then follows with the definition of the Cartesian product of a family of sets that $\bar{f}$ is a family with index set

I such that $\bar{f}_i \in X_i$ holds for any $i \in I$. With this, $\bar{i} \in I$ implies $\bar{f}_{\bar{i}} \in X_{\bar{i}}$, which clearly shows that $X_{\bar{i}}$ is nonempty, so that the implication in (3.868) is true. Because $\bar{i}$ is arbitrary, we may therefore conclude that the universal sentence (3.868) holds. Consequently, the negation of the existential sentence in (3.867) is true as well, which finding completes the proof of the implication '$\Rightarrow$' by contradiction.

Next, we prove the second part ('$\Leftarrow$') of the equivalence by contraposition, assuming the negation of $\exists i\,(i \in I \wedge X_i = \emptyset)$ to hold and showing that $\bigtimes_{i\in I} X_i \neq \emptyset$ follows to be true. The assumption implies with the Negation Law for existential conjunctions that the universal sentence (3.868) holds, which allows to prove $\emptyset \notin \mathrm{ran}(X)$. For this purpose, we apply (2.5) and verify the equivalent universal sentence

$$\forall Y\,(Y \in \mathrm{ran}(X) \Rightarrow Y \neq \emptyset), \tag{3.869}$$

letting Y be arbitrary and assuming $Y \in \mathrm{ran}(X)$ to be true. By definition of a range, there exists then a constant, say $\bar{k}$, such that $(\bar{k}, Y) \in X$ holds. Since X is a function/family, we may write $Y = X_{\bar{k}}$, and the definition of a domain shows that $\bar{k} \in I$ $[= \mathrm{dom}(X)]$ is true. The latter implies now $[Y =]\ X_{\bar{k}} \neq \emptyset$, which proves the implication in (3.869). Because Y was arbitrary, we may now infer from the truth of this implication the truth of the universal sentence (3.869), and therefore the truth of $\emptyset \notin \mathrm{ran}(X)$. This negation in turn implies with the Axiom of Choice that there exists a particular function $\bar{f} : \mathrm{ran}(X) \to \bigcup \mathrm{ran}(X)$ satisfying

$$\forall Y\,(Y \in \mathrm{ran}(X) \Rightarrow \bar{f}(Y) \in Y). \tag{3.870}$$

Since the family $(X_i)_{i\in I}$ is evidently a function $X : I \to \mathrm{ran}(X)$, we obtain the composition $\bar{f} \circ X : I \to \bigcup \mathrm{ran}(X)$ with Proposition 3.178, which is thus a family with index set I. Furthermore, we may show that the composition satisfies

$$\forall i\,(i \in I \Rightarrow (\bar{f} \circ X)_i \in X_i). \tag{3.871}$$

Letting i be arbitrary and assuming that $i \in I$ is true, the corresponding term X_i is clearly in the codomain/range of X, i.e. we have $X_i \in \mathrm{ran}(X)$. This further implies $\bar{f}(X_i) \in X_i$ with (3.870), which we may write also in the form $(\bar{f} \circ X)_i \in X_i$ by using the notation for compositions. Here, i is arbitrary, so that the universal sentence (3.871) follows indeed to be true. Then, since $\bar{f} \circ X$ is a family with index set I satisfying (3.871), we obtain now $\bar{f} \circ X \in \bigtimes_{i\in I} X_i$ with the definition of the Cartesian product of a family of sets. This finding demonstrates the existence of an element in $\bigtimes_{i\in I} X_i$ and therefore the truth of $\bigtimes_{i\in I} X_i \neq \emptyset$ in light of (2.42), completing the proof of the second part of the equivalence in (3.867) via contraposition.

Since I and X were initially arbitrary sets, we may furthermore conclude that the stated theorem holds. $\square$

The next proposition generalizes Proposition 3.8 (which we stated in the context of the Cartesian product of two sets) to the Cartesian product of a family of sets.

Proposition 3.246. *The following implication holds for any index set I and for any families $A = (A_i)_{i\in I}$ and $B = (B_i)_{i\in I}$ of sets.*

$$\forall i\,(i \in I \Rightarrow A_i \subseteq B_i) \;\Rightarrow\; \bigtimes_{i\in I} A_i \subseteq \bigtimes_{i\in I} B_i \tag{3.872}$$

Proof. We let I, A and B be arbitrary sets and assume $A = (A_i)_{i\in I}$ and $B = (B_i)_{i\in I}$ to be families of sets with index set I. To prove the implication directly, we assume

$$\forall i\,(i \in I \Rightarrow A_i \subseteq B_i) \tag{3.873}$$

and show that this implies the inclusion $\bigtimes_{i\in I} A_i \subseteq \bigtimes_{i\in I} B_i$, which means

$$\forall f\,(f \in \bigtimes_{i\in I} A_i \Rightarrow f \in \bigtimes_{i\in I} B_i) \tag{3.874}$$

by definition of a subset. For this purpose, we let f be arbitrary and assume $f \in \bigtimes_{i\in I} A_i$ to hold, so that

$$\forall i\,(i \in I \Rightarrow f_i \in A_i) \tag{3.875}$$

follows in particular to be true by definition of the Cartesian product of a family of sets. To prove that this implies $f \in \bigtimes_{i\in I} B_i$, we observe first that f is a family with index set I, so that it suffices to establish

$$\forall i\,(i \in I \Rightarrow f_i \in B_i). \tag{3.876}$$

We let i be arbitrary and assume $i \in I$, which gives on the one hand $A_i \subseteq B_i$ with (3.873) and therefore

$$\forall y\,(y \in A_i \Rightarrow y \in B_i) \tag{3.877}$$

with the definition of a subset; on the other hand, $i \in I$ implies $f_i \in A_i$ with (3.875), which in turn yields $f_i \in B_i$ with (3.877), proving the implication in (3.876). Since i is arbitrary, we may therefore conclude that the universal sentence (3.876) is true. Together with the assumption that f is a family with index set I, this implies $f \in \bigtimes_{i\in I} B_i$ according to Proposition 3.244. As f was also arbitrary, we may further conclude that the universal sentence (3.874) also holds, so that the inclusion $\bigtimes_{i\in I} A_i \subseteq \bigtimes_{i\in I} B_i$ follows to be true (by definition of a subset). Because I, A, and B were initially arbitrary sets, the proposition holds, as claimed. $\square$

Lemma 3.247. *The following implication holds for any index set I and for any families $A = (A_i)_{i \in I}$ and $B = (B_i)_{i \in I}$ of nonempty sets.*

$$\bigtimes_{i \in I} A_i \subseteq \bigtimes_{i \in I} B_i \;\Rightarrow\; \forall i \,(i \in I \Rightarrow A_i \subseteq B_i) \tag{3.878}$$

Proof. Letting I, A and B be arbitrary sets, we assume $A = (A_i)_{i \in I}$ and $B = (B_i)_{i \in I}$ to be families such that

$$\forall i \,(i \in I \Rightarrow A_i \neq \emptyset), \tag{3.879}$$

$$\forall i \,(i \in I \Rightarrow B_i \neq \emptyset). \tag{3.880}$$

Moreover, we assume the inclusion $\bigtimes_{i \in I} A_i \subseteq \bigtimes_{i \in I} B_i$ to holds and let then i be arbitrary. We prove now the implication $i \in I \Rightarrow A_i \subseteq B_i$ by contradiction, assuming that $i \in I$ and the negation $\neg A_i \subseteq B_i$ are both true. In view of the definition of a subset and the Negation Law for universal implication, there exists then a particular element $\bar{y}$ in A_i such that $\bar{y} \notin B_i$ holds. Let us consider now the restriction $A \restriction (I \setminus \{i\})$, where $I \setminus \{i\} \subseteq I$ holds according to (2.125), so that this restriction is a function/family with domain/index set $I \setminus \{i\}$ due to (3.566). In view of the preceding inclusion, it is true for any j that $j \in I \setminus \{i\}$ implies $j \in I$ (by definition of a subset) and therefore $A_j \neq \emptyset$ with (3.879). This fact evidently implies with the Emptiness Criterion for Cartesian products of families of sets that $\bigtimes_{j \in I \setminus \{i\}} A_j \neq \emptyset$ holds. Consequently, that Cartesian product has an element, say $\bar{f}$, which constitutes thus a family with index set $I \setminus \{i\}$ and terms satisfying

$$\forall j \,(j \in I \setminus \{i\} \Rightarrow \bar{f}_j \in A_j). \tag{3.881}$$

Forming then the singleton $\{(i, \bar{y})\}$, we have a function with domain $\{i\}$ because of (3.536). Observing now the truth of $\{i\} \cap (I \setminus \{i\}) = \emptyset$ in light of (2.111), we see that the domains of the functions $\{(i, \bar{y})\}$ and $\bar{f}$ are disjoint, so that these functions are compatible (see Exercise 3.73). Consequently, the union

$$u = \{(i, \bar{y})\} \cup \bar{f} \tag{3.882}$$

constitutes a function with domain $\{i\} \cup (I \setminus \{i\})$ (see Proposition 3.176). Here, we note that the assumed $i \in I$ implies $\{i\} \subseteq I$ with (2.184), which inclusion in turn implies

$$\begin{aligned} I &= (I \setminus \{i\}) \cup \{i\} \\ &= \{i\} \cup (I \setminus \{i\}) \end{aligned}$$

with (2.263) and the Commutative Law for the union of two sets. Thus, $\bar{f}$ is a function/family with domain I, which we now prove to be an element of the Cartesian product $\bigtimes_{i\in I} A_i$. For this purpose, we establish the truth of

$$\forall j\,(j \in I \Rightarrow u_j \in A_j), \tag{3.883}$$

letting j be arbitrary and assuming $j \in I$ $[= \{i\} \cup (I \setminus \{i\})]$ to hold. The definition of the union of two sets implies then the truth of the disjunction $j \in \{i\} \vee j \in I \setminus \{i\}$, which we use to prove $u_j \in A_j$ by cases. The first case $j \in \{i\}$ yields $j = i$ with (2.169), so that the previously established $\bar{y} \in A_i$ gives $\bar{y} \in A_j$ by means of substitution. Furthermore, we see in light of (3.882) and the definition of the union of a set system that $(i, \bar{y}) \in u$ holds, which we can write as $\bar{y} = u_i = u_j$, applying the notation for families and again substitution based on $j = i$. Therefore, $\bar{y} \in A_j$ implies the desired consequent $u_j \in A_j$ in the first case. The second case $j \in I \setminus \{i\}$ implies with (3.881) $\bar{f}_j \in A_j$, where evidently $(j, \bar{f}_j) \in \bar{f}$ holds, so that $(j, \bar{f}_j) \in u$ follows to be true with the definition of the union of a set system and (3.882). Writing this finding in function/family notation as $\bar{f}_j = u_j$, we now see that $\bar{f}_j \in A_j$ implies $u_j \in A_j$, as desired. Having thus completed the proof by cases, we can infer from the truth of $u_j \in A_j$ the truth of the universal sentence (3.883), so that the family u (with index set I) is indeed an element of the Cartesian product $\bigtimes_{i\in I} A_i$. Because of the assumed inclusion $\bigtimes_{i\in I} A_i \subseteq \bigtimes_{i\in I} B_i$, it follows then that u is also an element of the Cartesian product $\bigtimes_{i\in I} B_i$, which means that the terms of u satisfy

$$\forall j\,(j \in I \Rightarrow u_j \in B_j).$$

Consequently, the previously made assumption $i \in I$ implies $u_i \in B_i$; noting that (3.882) gives $(i, \bar{y}) \in u$, which we can write as $\bar{y} = u_i$, we thus obtain via substitution $\bar{y} \in B_i$. Recalling that $\bar{y} \notin B_i$ also holds, as arrived at contradiction, so that the proof of the implication $i \in I \Rightarrow A_i \subseteq B_i$ is now complete. Here, i was arbitrary, so that the universal sentence in (3.878) follows then to be true. This in turn proves the implication (3.878), and as I, A and B were initially arbitrary sets, we may therefore conclude that the stated lemma holds. □

We generalize now the Equality Criterion for Cartesian products of two sets to families of sets.

Theorem 3.248 (Equality Criterion for Cartesian products of families of sets). *The following equivalence holds for any (index) set I and for any families $A = (A_i)_{i\in I}$ and $B = (B_i)_{i\in I}$ of nonempty sets.*

$$\forall i\,(i \in I \Rightarrow A_i = B_i) \;\Leftrightarrow\; \bigtimes_{i\in I} A_i = \bigtimes_{i\in I} B_i. \tag{3.884}$$

Proof. We take arbitrary sets I, A and B such that $A = (A_i)_{i\in I}$ and $B = (B_i)_{i\in I}$ are families of sets where

$$\forall i\,(i \in I \Rightarrow A_i \neq \emptyset), \tag{3.885}$$

$$\forall i\,(i \in I \Rightarrow B_i \neq \emptyset). \tag{3.886}$$

To prove the first part ('$\Rightarrow$') of the equivalence, we assume the universal sentence

$$\forall i\,(i \in I \Rightarrow A_i = B_i) \tag{3.887}$$

to be true. This assumption allows us to establish the conjunction

$$\forall i\,(i \in I \Rightarrow A_i \subseteq B_i) \wedge \forall i\,(i \in I \Rightarrow B_i \subseteq A_i). \tag{3.888}$$

Indeed, letting i be arbitrary and assuming $i \in I$ to be true, we obtain $A_i = B_i$ with (3.887), which equation implies $A_i \subseteq B_i$ and $B_i \subseteq A_i$ with (2.22); since i is arbitrary, we may therefore conclude that both of the universal sentences in (3.888) are true. These universal sentences imply now

$$\bigtimes_{i\in I} A_i \subseteq \bigtimes_{i\in I} B_i \wedge \bigtimes_{i\in I} B_i \subseteq \bigtimes_{i\in I} A_i \tag{3.889}$$

with (3.872), so that the desired equation

$$\bigtimes_{i\in I} A_i = \bigtimes_{i\in I} B_i \tag{3.890}$$

follows to be true with (2.22).

To prove the second part ('$\Leftarrow$') of the equivalence in (3.884), we assume (3.890) to be true, which assumption implies then the truth of the conjunction (3.889) with (2.22). These two inclusions further imply the universal sentences in (3.888) because of (3.878), which we use now to establish (3.887). Letting i be arbitrary and assuming $i \in I$ to be true, the universal sentences in (3.888) give the inclusions $A_i \subseteq B_i$ and $B_i \subseteq A_i$, which in turn imply $A_i = B_i$ with (2.22), as desired. Here, i is arbitrary, so that (3.887) follows to be true indeed.

We thus completed the proof of the equivalence (3.884), and as the sets I, A and B were initially arbitrary, we may therefore conclude that the theorem holds. $\square$

Proposition 3.249. *For any set I, any family $(X_i)_{i\in I}$ of sets and any $j \in I$, there exists a unique function π_j with domain $\bigtimes_{i\in I} X_i$ such that*

$$\forall f\,(f \in \bigtimes_{i\in I} X_i \Rightarrow \pi_j(f) = f_j). \tag{3.891}$$

holds. Moreover, X_j is a codomain of this function.

Proof. We let I, $(X_i)_{i\in I}$ and j be an arbitrary such that $(X_i)_{i\in I}$ is a family of sets and such that $j \in I$ holds. We now apply Function definition by replacement and verify for this purpose

$$\forall f\,(f \in \bigtimes_{i\in I} X_i \Rightarrow \exists! y\,(y = f_j)), \tag{3.892}$$

letting f be an arbitrary set and assuming $f \in \bigtimes_{i\in I} X_i$ to be true. Thus, f is a family of sets with index set I, so that the initial assumption $j \in I$ gives the uniquely specified function value f_j. Consequently, the uniquely existential sentence in (3.892) is true according to (1.109). Since f is arbitrary, we may therefore conclude that the universal sentence (3.892) holds, which implies the unique existence of a function π_j with domain $\bigtimes_{i\in I} X_i$ satisfying (3.891). To prove that X_j is a codomain of π_j, that is, to prove the inclusion $\mathrm{ran}(\pi_j) \subseteq X_j$, we verify

$$\forall y\,(y \in \mathrm{ran}(\pi_j) \Rightarrow y \in X_j). \tag{3.893}$$

To do this, we take an arbitrary y and assume $y \in \mathrm{ran}(\pi_j)$, so that there exists a constant, say $\bar{f}$, with $(\bar{f}, y) \in \pi_j$, using the definition of a range. On the one hand, we may write this as $y = \pi_j(\bar{f})$, because π_j is a function. On the other hand, $(\bar{f}, y) \in \pi_j$ gives with the definition of a domain $\bar{f} \in \bigtimes_{i\in I} X_i$ and then $\pi_j(\bar{f}) = \bar{f}_j$ due to (3.891), so that we obtain $y = \bar{f}_j$ via substitution. Let us now observe that $\bar{f} \in \bigtimes_{i\in I} X_i$ implies by definition of the Cartesian product of a family of sets that $\bar{f}_i \in X_i$ holds for any $i \in I$. Thus, the assumed $j \in I$ yields $[y =]\ \bar{f}_j \in X_j$, which finding proves the implication in (3.893). As y is arbitrary, we may infer from this the truth of the universal sentence (3.893), which gives $\mathrm{ran}(\pi_j) \subseteq X_j$ with the definition of a subset. Thus, X_j is indeed a codomain of π_j.

Since I, $(X_i)_{i\in I}$ and j were initially arbitrary, we may therefore conclude that the proposition is true. □

Definition 3.61 (Projection function on the Cartesian product of a family of sets). For any set I, any family $(X_i)_{i\in I}$ of sets and any $j \in I$ we call

$$\pi_j : \bigtimes_{i\in I} X_i \to X_j, \quad f \mapsto \pi_j(f) = f_j \tag{3.894}$$

the *projection function* from $\bigtimes_{i\in I} X_i$ to X_j or the j-th *projection map* on $\bigtimes_{i\in I} X_i$.

Theorem 3.250 (Surjectivity of projection functions with nonempty domain). *It is true for any nonempty index set I, any family $(X_i)_{i\in I}$ of* *nonempty sets and any index $j \in I$ that the j-th projection map on $\bigtimes_{i \in I} X_i$ is a surjection, i.e.*

$$\forall i \,(i \in I \Rightarrow X_i \neq \emptyset) \;\Rightarrow\; \forall j \,(j \in I \Rightarrow \pi_j : \bigtimes_{i \in I} X_i \twoheadrightarrow X_j). \tag{3.895}$$

Proof. We take arbitrary I, $(X_i)_{i \in I}$ and j, assuming $(X_i)_{i \in I}$ to be a family of sets with index set $I \neq \emptyset$ and assuming then also the universal sentence

$$\forall i \,(i \in I \Rightarrow X_i \neq \emptyset) \tag{3.896}$$

to be true. Next, we let also j be arbitrary and assume that $j \in I$ is true, so that the projection function $\pi_j : \bigtimes_{i \in I} X_i \to X_j$ is defined. To prove that it constitutes a surjection with range X_j, we apply the Surjection Criterion and verify accordingly

$$\forall y \,(y \in X_j \Rightarrow \exists f \,(\pi_j(f) = y)), \tag{3.897}$$

letting $y \in X_j$ be arbitrary. We may now apply Function definition by replacement to establish a unique family F with domain I such that

$$\forall i \,(i \in I \Rightarrow ([i = j \Rightarrow F(i) = \{y\}] \,\wedge\, [i \neq j \Rightarrow F(i) = X_i])). \tag{3.898}$$

To do this, we prove accordingly the universal sentence

$$\forall i \,(i \in I \Rightarrow \exists! Y \,([i = j \Rightarrow Y = \{y\}] \,\wedge\, [i \neq j \Rightarrow Y = X_i])), \tag{3.899}$$

letting i be arbitrary and assuming $i \in I$ to be true. Using the fact that the Law of the Excluded Middle gives us the true disjunction $i = j \,\vee\, i \neg j$, we may prove the existential part of the desired uniquely existential sentence by cases. In the first case $i = j$, we observe that replacing the variable Y by the constant $\{y\}$ (which is the uniquely specified singleton formed by the constant y) yields the true implication $i = j \Rightarrow \{y\} = \{y\}$ (in which both the antecedent and the consequent are true) as well as the true implication $i \neq j \Rightarrow Y = X_i$ (which has a false antecedent). Then, the conjunction of these two implications is also true, so that there exists indeed a Y for which the conjunction in (3.899) holds. In the second case $i \neq j$, we replace now Y by the set X_i, so that the first implication $i = j \Rightarrow X_i = \{y\}$ has now a false antecedent and the second implication $i \neq j \Rightarrow X_i = X_i$ both a true antecedent and a true consequent. Thus, both implications are true for the choice X_j, which proves the existential part also for the second case.

To establish the uniqueness part, we prove

$$\begin{aligned} \forall Y, Y' \,([([i = j \Rightarrow Y = \{y\}] \,\wedge\, [i \neq j \Rightarrow Y = X_i]) \\ \wedge\, ([i = j \Rightarrow Y' = \{y\}] \,\wedge\, [i \neq j \Rightarrow Y' = X_i])] \Rightarrow Y = Y'), \end{aligned} \tag{3.900}$$

letting Y and Y' be arbitrary and assuming the two conjunctions

$$[i = j \Rightarrow Y = \{y\}] \wedge [i \neq j \Rightarrow Y = X_i]$$
$$[i = j \Rightarrow Y' = \{y\}] \wedge [i \neq j \Rightarrow Y' = X_i]$$

to be true. Considering the same cases as before, we have that the first case $i = j$ implies $Y = \{y\}$ as well as $Y' = \{y\}$, and that the second case $i \neq j$ implies $Y = X_i$ as well as $Y' = X_i$. Consequently, substitution yields $Y = Y'$ for both cases, and since Y and Y' are arbitrary, we may therefore conclude that the uniqueness part (3.900) holds. Thus, the proof of the uniquely existential sentence is complete, and as i was arbitrary, we may further conclude that (3.899) is true.

Consequently, there exists a unique function F with domain I satisfying (3.898), and we may write F then as the family $(F_i)_{i \in I}$. This family in turn defines the Cartesian product $\bigtimes_{i \in I} F_i$, which we now prove to be nonempty.

For this purpose, we show that

$$\forall i\, (i \in I \Rightarrow F_i \neq \emptyset) \tag{3.901}$$

holds. Letting i be arbitrary and assuming $i \in I$ to hold, we prove the desired consequent $F_i \neq \emptyset$ by the same cases as before. The first case $i = j$ implies $[F_i =]\ F(i) = \{y\}$ with (3.898), for which singleton we have $y \in \{y\}$ according to (2.153) and therefore evidently $[F_i =]\ \{y\} \neq \emptyset$. The second case $i \neq j$ implies $[F_i =]\ F(i) = X_i$ again with (3.898), for which set the assumed $i \in I$ implies $[F_i =]\ X_i \neq \emptyset$ with the initial assumption (3.896). We thus found $F_i \neq \emptyset$ in any case, where i was arbitrary, so that (3.901) follows to be indeed true. This universal sentence implies now with the Negation Law for existential conjunctions $\neg\exists i\, (i \in I \wedge F_i = \emptyset)$, so that the negation $\bigtimes_{i \in I} F_i \neq \emptyset$ follows to be true with the Emptiness Criterion for Cartesian products of families of sets in connection with the Law of Contraposition. This negation in turn demonstrates that there exists an element in $\bigtimes_{i \in I} F_i$, say $\bar{f}$, for which the assumed $j \in I$ implies $\bar{f}_j \in F_j$ by definition of the Cartesian product of a family of sets. As $j \in I$ and $j = j$ imply $[F_j =]\ F(j) = \{y\}$ with (3.898), substitution gives us $\bar{f}_j \in \{y\}$ and therefore $\bar{f}_j = y$ with (2.169).

Our next task is to prove that $\bar{f}$ is an element also of the Cartesian product $\bigtimes_{i \in I} X_i$. We already know that $\bar{f}$ is a family with index set I, so it only remains for us to demonstrate the truth of

$$\forall i\, (i \in I \Rightarrow \bar{f}_i \in X_i). \tag{3.902}$$

Letting i be arbitrary and assuming that $i \in I$ holds, we consider once again the two cases $i = j$ and $i \neq j$. If $i = j$ is true, we obtain $\bar{f}_i = \bar{f}_j = y$, so that the previous assumption $y \in X_j$ gives $\bar{f}_i \in X_j$ and therefore $\bar{f}_i \in X_i$ via substitution based on the current case assumption. If $i \neq j$ is true, we obtain from $i \in I$ and $\bar{f} \in \bigtimes_{i \in I} F_i$ (by definition of the Cartesian product of a family of sets) $\bar{f}_i \in F_i$, where $[F_i =]\ F(i) = X_i$ follows to be true with (3.898), so that substitution yields $\bar{f}_i \in X_i$. Thus, the desired consequent of the implication in (3.902) holds in any case. Because i is arbitrary, we may infer from this the truth of the universal sentence (3.902), which finding completes the verification of $\bar{f}$ as an element also of the Cartesian product $\bigtimes_{i \in I} X_i$. This means that $\bar{f}$ is an element of the domain of the projection function π_j, so that the associated value is given by $\pi_j(\bar{f}) = \bar{f}_j$. Combining this with the previously established equation $\bar{f}_j = y$, we arrive at $\pi_j(\bar{f}) = y$, which in turn proves the existential sentence in (3.897). Here, y was arbitrary, so that the universal sentence (3.897) follows now to be true, and this finally implies that π_j is a surjection from $\bigtimes_{i \in I} X_i$ to X_j. Because I, $(X_i)_{i \in I}$ and j were initially arbitrary, we may therefore conclude that the stated theorem is indeed true. $\square$

3.4.7. Partially ordered sets of functions

In this section, we consider sets of functions from a set X to a set Y, and we will see that any reflexive partial ordering $\leq$ of the codomain Y may be used to define a reflexive partial ordering $\preceq$ of the set of functions Y^X.

Proposition 3.251. *For any nonempty set X, any set Y and any reflexive partial ordering $\leq$ of Y, it is true that there exists a unique set $\preceq$ such that a set Z is in $\preceq$ iff Z is in the Cartesian product $Y^X \times Y^X$ and moreover if Z is the ordered pair (f,g) formed by some functions f and g in Y^X for which the value of f at any x is less than or equal to the value of g at x, i.e. it is true that*

$$\begin{aligned}&\exists!\preceq \forall Z\,(Z\in\preceq\Leftrightarrow[Z\in Y^X\times Y^X\\&\quad\wedge\ \exists f,g\,(f,g\in Y^X\ \wedge\ \forall x\,(x\in X\Rightarrow f(x)\leq g(x)))\ \wedge\ (f,g)=Z)]).\end{aligned}$$

This set $\preceq$ satisfies

$$\forall f,g\,(f,g\in Y^X\Rightarrow[f\preceq g\Leftrightarrow\forall x\,(x\in X\Rightarrow f(x)\leq g(x))]) \tag{3.903}$$

and is a reflexive partial ordering of the set of functions Y^X.

Proof. We let X, Y and $\leq$ be arbitrary sets, assume $X\neq\emptyset$, and assume moreover $\leq$ to be a reflexive partial ordering of Y. We may then evidently apply the Axiom of Specification and the equality Criterion for sets to form the stated uniquely existential sentence. Thus, the set $\preceq$ satisfies the universal sentence

$$\begin{aligned}&\forall Z\,(Z\in\preceq\Leftrightarrow[Z\in Y^X\times Y^X\\&\quad\wedge\ \exists f,g\,(f,g\in Y^X\ \wedge\ \forall x\,(x\in X\Rightarrow f(x)\leq g(x))\ \wedge\ (f,g)=Z)]).\end{aligned} \tag{3.904}$$

Clearly, $Z\in\preceq$ implies in particular $Z\in Y^X\times Y^X$ for any Z, so that we have $\preceq\subseteq Y^X\times Y^X$ by definition of a subset, and this inclusion shows that $\preceq$ is a binary relation on Y^X.

Let us now verify that the binary relation $\preceq$ is also characterized by(3.903), letting f and g be arbitrary sets and assuming $f,g\in Y^X$ to be true. To prove the first part ('$\Rightarrow$') of the equivalence directly, we assume that $f\preceq g$ holds, which we may write also as $(f,g)\in\preceq$. This in turn implies with (3.904) in particular that there are elements of Y^X, say $\bar{f}$ and $\bar{g}$ such that the universal sentence

$$\forall x\,(x\in X\Rightarrow\bar{f}(x)\leq\bar{g}(x)) \tag{3.905}$$

and $(\bar{f},\bar{g})=(f,g)$ are true. The latter equation yields with the Equality Criterion for ordered pairs $\bar{f}=f$ and $\bar{g}=g$. Since the assumptions $f,g\in$

Y^X and the previously established $\bar{f}, \bar{g} \in Y^X$ show that $\bar{f}$ and f as well as $\bar{g}$ and g are functions with domain X, we may apply the Equality Criterion for functions to infer from the preceding equations the truth of the universal sentences

$$\forall x\, (x \in X \Rightarrow \bar{f}(x) = f(x)), \tag{3.906}$$
$$\forall x\, (x \in X \Rightarrow \bar{g}(x) = g(x)). \tag{3.907}$$

After this preparatory work, we are now in the position to establish the desired consequent

$$\forall x\, (x \in X \Rightarrow f(x) \leq g(x)) \tag{3.908}$$

of the first implication '⇒' in (3.903). Letting $\bar{x}$ be arbitrary and assuming $\bar{x} \in X$ to be true, we obtain on the one hand with (3.905) the inequality $\bar{f}(\bar{x}) \leq \bar{g}(\bar{x})$, and on the other hand with (3.906) – (3.907) the equations $\bar{f}(\bar{x}) = f(\bar{x})$ and $\bar{g}(\bar{x}) = g(\bar{x})$. Applying now substitutions based on these equations to the preceding inequality, we obtain $f(\bar{x}) \leq g(\bar{x})$, proving the implication in (3.908). As $\bar{x}$ was arbitrary, we may therefore conclude that the universal sentence (3.908) is true, so that the proof of the first part of the equivalence in (3.903) is complete.

Regarding the second part ('⇐'), we now assume (3.908) to be true. On the one hand, as we assumed $f, g \in Y^X$ to be true, we obtain for the ordered pair $Z = (f, g)$

$$Z \in Y^X \times Y^X \tag{3.909}$$

with the definition of the Cartesian product of two sets. On the other hand, we see that there exist constants f and g which satisfy the multiple conjunction

$$f, g \in Y^X \,\wedge\, \forall x\, (x \in X \Rightarrow f(x) \leq g(x)) \,\wedge\, (f, g) = Z.$$

Then, the conjunction of (3.909) and the preceding existential sentence implies with (3.904) $[Z =]\ (f, g) \in \preceq$, which we may write also as $f \preceq g$ (since $\preceq$ is a binary relation). Thus, the second part of the equivalence in (3.903) also holds, so that the proof of the equivalence is complete. As f and g were arbitrary, we may now further conclude that the proposed universal sentence (3.903) is indeed true.

Next, we prove that the binary relation $\preceq$ on Y^X is reflexive, by verifying

$$\forall f\, (f \in Y^X \Rightarrow f \preceq f). \tag{3.910}$$

We take an arbitrary set f, assume $f \in Y^X$ to be true (so that f is a function from X to Y), and we establish the truth of

$$\forall x\, (x \in X \Rightarrow f(x) \leq f(x)), \tag{3.911}$$

which will imply the desired consequent $f \preceq f$ with (3.903). Indeed, letting $x \in X$ be arbitrary, so that the corresponding function value $f(x)$ is an element of Y according to the Function Criterion, we obtain $f(x) \leq f(x)$ with the fact that partial ordering $\leq$ of Y is reflexive. Because x is arbitrary, we may therefore conclude that (3.911) holds, so that $f \preceq f$ follows to be true with (3.903). As f is also arbitrary, we may now infer from this finding the truth of (3.910), which means that $\preceq$ is reflexive.

To establish the antisymmetry of $\preceq$, we verify

$$\forall f, g\,(f, g \in Y^X \Rightarrow [(f \preceq g \wedge g \preceq f) \Rightarrow f = g]), \tag{3.912}$$

letting f and g be arbitrary and assuming first $f, g \in Y^X$ and then the conjunction $f \preceq g \wedge g \preceq f$ to be true. The latter inequalities give with (3.903)

$$\forall x\,(x \in X \Rightarrow f(x) \leq g(x)), \tag{3.913}$$
$$\forall x\,(x \in X \Rightarrow g(x) \leq f(x)), \tag{3.914}$$

which universal sentences allow us to establish

$$\forall x\,(x \in X \Rightarrow f(x) = g(x)). \tag{3.915}$$

To do this, we let x be arbitrary and assume $x \in X$, which yields with (3.913) and (3.914) $f(x) \leq g(x)$ and $g(x) \leq f(x)$. These two inequalities in turn imply $f(x) = g(x)$ with the antisymmetry of the reflexive partial ordering $\leq$ of Y. As x is arbitrary, we may therefore conclude that (3.915) holds, and this universal sentence implies the desired $f = g$ with the Equality Criterion for functions. Because f and g are arbitrary, we may now further conclude that the universal sentence (3.912) is true, which shows that $\preceq$ is antisymmetric.

It only remains for us to show that $\preceq$ is transitive, i.e. that $\preceq$ has the definite property

$$\forall f, g, h\,(f, g, h \in Y^X \Rightarrow [(f \preceq g \wedge g \preceq h) \Rightarrow f \preceq h]). \tag{3.916}$$

We take arbitrary f, g and h, assume $f, g, h \in Y^X$, and assume moreover $f \preceq g$ and $g \preceq h$, which inequalities imply

$$\forall x\,(x \in X \Rightarrow f(x) \leq g(x)), \tag{3.917}$$
$$\forall x\,(x \in X \Rightarrow g(x) \leq h(x)) \tag{3.918}$$

with (3.903). To establish the desired consequent $f \preceq h$, we prove

$$\forall x\,(x \in X \Rightarrow f(x) \leq h(x)), \tag{3.919}$$

letting x be arbitrary in X. Consequently, we obtain $f(x) \leq g(x)$ and $g(x) \leq h(x)$ with (3.917) and (3.918), respectively, and these two inequalities imply $f(x) \leq h(x)$ because of the transitivity of the partial ordering $\leq$. This finding proves already the implication in (3.919), and since x is arbitrary, we may therefore conclude that (3.919) holds. The truth of this universal sentence implies now the truth of $f \preceq h$ with (3.903), from which we may then infer the truth of the universal sentence (3.916), because f, g and h were arbitrary. Therefore, the reflexive and antisymmetric binary relation $\preceq$ on Y^X is also transitive, and constitutes thus a reflexive partial ordering of Y^X. Since X, Y and $\leq$ were initially arbitrary sets, we may finally conclude that the proposition is true. □

Theorem 3.252 (Characterization of lower & upper bounds for a family of functions). *For any sets I, X and Y, any reflexive partial ordering $\leq$ of Y, any family $f = (f_i)_{i\in I}$ of functions from X to Y and any function g from X to Y, it is true that*

a) g is a lower bound for $(f_i)_{i\in I}$ (with respect to the reflexive partial ordering $\preceq$ of Y^X) iff $g(x)$ is a lower bound for $f^{(x)} = (f_i(x))_{i\in I}$ (with respect to the reflexive partial ordering $\leq$ of Y) for any $x \in X$.

b) g is an upper bound for $(f_i)_{i\in I}$ iff $g(x)$ is an upper bound for $f^{(x)} = (f_i(x))_{i\in I}$ for any $x \in X$.

Proof. We let I, X, Y, $\leq$, f and g be arbitrary such that $\leq$ is a reflexive partial ordering of Y, such that $f = (f_i)_{i\in I}$ is a family in Y^X with index set I, and such that $g \in Y^X$ hold. Regarding the first part ('$\Rightarrow$') of the equivalence in b), we assume that g is an upper bound for $\mathrm{ran}(f)$, so that

$$\forall h\,(h \in \mathrm{ran}(f) \Rightarrow h \preceq g) \tag{3.920}$$

holds. We then take arbitrary $\bar{x}$, assume $\bar{x} \in X$ to be true, and show that this implies

$$\forall y\,(y \in \mathrm{ran}(f^{(\bar{x})}) \Rightarrow y \leq g(\bar{x})). \tag{3.921}$$

For this purpose, we let y be arbitrary and assume $y \in \mathrm{ran}(f^{(\bar{x})})$ to be true, so that there exists by definition of a range a constant, say $\bar{k}$, with $(\bar{k}, y) \in f^{(\bar{x})}$. This yields on the one hand in function/family notation $y = f^{(\bar{x})}(\bar{k}) = f_{\bar{k}}(\bar{x})$, and on the other hand $\bar{k} \in I$ $[= \mathrm{dom}(f^{(\bar{x})})]$ by definition of a domain. Let us observe here that $\bar{k} \in I$ implies the unique existence of the term $f_{\bar{k}} = f(\bar{k})$, which equation we may write in function notation as $(\bar{k}, f_{\bar{k}}) \in f$. By definition of a range, we therefore obtain $f_{\bar{k}} \in \mathrm{ran}(f)$, which implies $f_{\bar{k}} \preceq g$ with (3.920), and therefore

$$\forall x\,(x \in X \Rightarrow f_{\bar{k}}(x) \leq g(x)) \tag{3.922}$$

with (3.903). Then, the assumed $\bar{x} \in X$ yields $[y =]\ f_{\bar{k}}(\bar{x}) \leq g(\bar{x})$, and this finding proves the implication in (3.921). As y is arbitrary, we may therefore conclude that the universal sentence (3.921) holds, so that $g(\bar{x})$ is an upper bound for (the range of) the sequence $f^{(\bar{x})}$. Since $\bar{x}$ was also arbitrary, we may now further conclude that the first part of the stated equivalence holds.

Regarding the second part ('$\Leftarrow$'), we now assume that $g(x)$ is an upper bound for the sequence $f^{(x)}$ for all $x \in X$, and we show that g follows to be an upper bound for $\mathrm{ran}(f)$, i.e. that (3.920) follows to be true. For this purpose, we let h be arbitrary and assume $h \in \mathrm{ran}(f)$ to be true, so that there is (by definition of a range) a particular constant $\bar{k}$ with $(\bar{k}, h) \in f$. We therefore obtain $h = f_{\bar{k}}$ and $\bar{k} \in I$ $[= \mathrm{dom}(f)]$, where the former finding implies

$$\forall x\, (x \in X \Rightarrow h(x) = f_{\bar{k}}(x)) \tag{3.923}$$

with the Equality Criterion for functions. To establish the desired consequent $h \preceq g$, we verify now

$$\forall x\, (x \in X \Rightarrow h(x) \leq g(x)), \tag{3.924}$$

letting $\bar{x} \in X$ be arbitrary, so that $g(\bar{x})$ is (by assumption) an upper bound for the range of the sequence $f^{(\bar{x})}$; thus, the constant $\bar{x}$ satisfies the universal sentence (3.921). Furthermore, $\bar{x} \in X$ implies with (3.923) that $h(\bar{x}) = f_{\bar{k}}(\bar{x}) = f^{(\bar{x})}(\bar{k})$ holds. We may write the resulting equation $h(\bar{x}) = f^{(\bar{x})}(\bar{k})$ also as $(\bar{k}, h(\bar{x})) \in f^{(\bar{x})}$, so that $h(\bar{x}) \in \mathrm{ran}(f^{(\bar{x})})$ follows to be true by definition of a range, and this implies $h(\bar{x}) \leq g(\bar{x})$ with (3.921). Thus, the proof of the implication in (3.924) is complete, and since $\bar{x}$ was arbitrary, we may therefore conclude that (3.924) is true. This universal sentence in turn implies $h \preceq g$ with (3.903), proving the implication in (3.920). Because h was arbitrary, we may infer from this the truth of the universal sentence (3.920), which means that g is indeed an upper bound for $\mathrm{ran}(f)$.

Thus, the proof of the equivalence b) is complete, and since I, X, Y, $\leq$, f and g were arbitrary, we may further conclude that Part b) of the theorem is true. □

Exercise 3.108. Prove Part a) of Theorem 3.252.

(Hint: Proceed in analogy to the proof of Part b).)

Exercise 3.109. Show for any nonempty set X, any set Y and any irreflexive partial ordering $<$ of Y that there exists a unique set $\prec$ such that a set Z is in $\prec$ iff Z is in the Cartesian product $Y^X \times Y^X$ and moreover if Z is the ordered pair (f, g) formed by some functions f and g in Y^X for which the value of f at any x is less than the value of g at x, i.e. such that

$$\begin{aligned}&\exists! \prec \forall Z\,(Z \in \prec \Leftrightarrow [Z \in Y^X \times Y^X \\ &\quad \wedge \exists f, g\,(f, g \in Y^X \wedge \forall x\,(x \in X \Rightarrow f(x) < g(x))) \wedge (f, g) = Z)]).\end{aligned}$$

Prove that this set $\prec$ satisfies

$$\forall f, g\,(f, g \in Y^X \Rightarrow [f \prec g \Leftrightarrow \forall x\,(x \in X \Rightarrow f(x) < g(x))]) \tag{3.925}$$

and that $\prec$ is an irreflexive partial ordering of the set of functions Y^X. (Hint: Apply a proof by contradiction to establish the irreflexivity of $\prec$.)

Exercise 3.110. Verify for any sets X and Y and any reflexive partial ordering $\leq$ of Y (inducing the irreflexive partial ordering $<$ of Y) that a function f from X to Y is less than or equal to a function g from X to Y if f is less than g, i.e. that

$$\forall f, g\,(f, g \in Y^X \Rightarrow [f \prec g \Rightarrow f \preceq g]) \tag{3.926}$$

holds, where $\preceq$ and $\prec$ are defined by $\leq$ and $<$, respectively.

Theorem 3.253 (Generation of complete lattices of functions). *For any set X and any complete lattice $(Y, \leq)$, it is true that the partially ordered set $(Y^X, \preceq)$ is itself a complete lattice.*

Proof. We let X, Y and $\leq$ be arbitrary sets and assume $(Y, \leq)$ to be a complete lattice. Since $\leq$ is then especially a reflexive partial ordering of Y, we may indeed define the reflexive partial ordering $\preceq$ of Y^X according to Proposition 3.251. Let us observe here that the set Y is nonempty because we assumed $(Y, \leq)$ to be a lattice. Consequently, the set of function Y^X is also nonempty in view of Proposition 3.155. We now verify that the partially ordered set $(Y^X, \preceq)$ has the definite property

$$\forall A\,(A \subseteq Y^X \Rightarrow \exists S, I\,(S, I \in Y^X \wedge S = \overset{\preceq}{\sup} A \wedge I = \overset{\preceq}{\inf} A)), \tag{3.927}$$

letting A be arbitrary and assuming $A \subseteq Y^X$ to be true. Thus, every element of A is a function from X to Y. We first demonstrate that there exists, for any element x of the domain X of the functions in A, a unique set F_x consisting of the values (within the codomain Y) at x of all the functions in A, i.e.

$$\forall x\,(x \in X \Rightarrow \exists! F_x\, \forall y\,(y \in F_x \Leftrightarrow [y \in Y \wedge \exists f\,(f \in A \wedge y = f(x))])). \tag{3.928}$$

Letting x be arbitrary and assuming $x \in X$ to be true, we may evidently establish the uniquely existential sentence by applying the Axiom of Specification and the Equality Criterion for sets. Thus, the set F_x satisfies

$$\forall y\,(y \in F_x \Leftrightarrow [y \in Y \wedge \exists f\,(f \in A \wedge y = f(x))]), \tag{3.929}$$

which shows in particular that $y \in F_x$ implies $y \in Y$ for any y, so that $F_x \subseteq Y$ holds by definition of a subset. As x was arbitrary, we may therefore conclude that the universal sentence (3.928) is true. Consequently, the universal sentence (3.929) and the inclusion $F_x \subseteq Y$ hold then also for any $x \in X$. After this preparation, we show via Function definition by replacement that there are (unique) functions S and I with domain X satisfying

$$\forall x\,(x \in X \Rightarrow S(x) = \overset{\leq}{\sup} F_x), \tag{3.930}$$

$$\forall x\,(x \in X \Rightarrow I(x) = \overset{\leq}{\inf} F_x), \tag{3.931}$$

which task we accomplish by verifying

$$\forall x\,(x \in X \Rightarrow \exists! y\,(y = \overset{\leq}{\sup} F_x)), \tag{3.932}$$

$$\forall x\,(x \in X \Rightarrow \exists! y\,(y = \overset{\leq}{\inf} F_x)). \tag{3.933}$$

We take an arbitrary $x \in X$, so that the inclusion $F_x \subseteq Y$ holds, as mentioned before. Then, since $(Y, \leq)$ is a complete lattice, there are elements of Y, say $\bar{S}_x$ and $\bar{I}_x$, such that $\bar{S}_x = \sup^{\leq} F_x$ and $\bar{I}_x = \inf^{\leq} F_x$. Consequently, the uniquely existential sentences in (3.932) and (3.933) are both true according to (1.109). As x was arbitrary, both of the universal sentences (3.932) and (3.933) follow then to be also true. Consequently, there are unique functions S and I with domain X such that (3.930) and (3.931) hold.

Let us check now that Y is a codomain of S and I, i.e. that the inclusions $\mathrm{ran}(S) \subseteq Y$ and $\mathrm{ran}(I) \subseteq Y$ hold. Letting y and y' be arbitrary and assuming first $y \in \mathrm{ran}(S)$ as well as $y' \in \mathrm{ran}(I)$ to be true, there exist by definition of a range constants, say $\bar{x}$ and $\bar{x}$', with $(\bar{x}, y) \in S$ and $(\bar{x}', y') \in I$. Because we established S and I already as functions (with domain $\mathrm{dom}(S) = \mathrm{dom}(S) = X$), we obtain on the one hand $\bar{x} \in X$ [$= \mathrm{dom}(S)$] as well as $\bar{x}' \in X$ [$= \mathrm{dom}(I)$] with the definition of a domain, and on the other hand we may write $y = S(\bar{x})$ as well as $y' = I(\bar{x}')$. Here, $\bar{x} \in X$ and $\bar{x}' \in X$ imply [$y =$] $S(\bar{x}) = \sup^{\leq} F_{\bar{x}}$ as well as [$y' =$] $I(\bar{x}') = \inf^{\leq} F_{\bar{x}}$ with (3.930) and (3.931), respectively. As mentioned earlier, the preceding supremum and infimum are both in Y because of the completeness of the lattice $(Y, \leq)$. We thus showed that $y \in \mathrm{ran}(S)$ implies $y \in Y$ and that $y' \in \mathrm{ran}(I)$ implies $y' \in Y$. Since y and y' were arbitrary, we may infer from the truth of these implications the truth of the two inclusions $\mathrm{ran}(S) \subseteq Y$ and $\mathrm{ran}(I) \subseteq Y$, using the definition of a subset. Thus, S and I are both functions from X to Y.

Our next task is to demonstrate that the two functions $S : X \to Y$ and $I : X \to Y$ satisfy also the equations in (3.927), that is, $S = \sup^{\preceq} A$ and $I = \inf^{\preceq} A$. We first show that S is an upper bound and I a lower bound for A with respect to $\preceq$, i.e. that

$$\forall h\,(h \in A \Rightarrow h \preceq S), \tag{3.934}$$

$$\forall h\,(h \in A \Rightarrow I \preceq h) \tag{3.935}$$

hold. We let h be arbitrary, assume $h \in A$ to be true, so that the initial assumption $A \subseteq Y^X$ yields $h \in Y^X$ by definition of a subset, and therefore $h : X \Rightarrow Y$. We now show that this implies $h \preceq S$ as well as $I \preceq h$, i.e.

$$\forall x\,(x \in X \Rightarrow h(x) \leq S(x)), \tag{3.936}$$

$$\forall x\,(x \in X \Rightarrow I(x) \leq h(x)), \tag{3.937}$$

using (3.903). We let x be arbitrary and assume $x \in X$ to be true, which yields $S(x) = \sup^{\leq} F_x$ with (3.930) and $I(x) = \inf^{\leq} F_x$ with (3.931). Since the supremum $S(x)$ is an upper bound and the infimum $I(x)$ a lower bound for F_x with respect to $\leq$, we have the true universal sentences

$$\forall y\,(y \in F_x \Rightarrow y \leq S(x)), \tag{3.938}$$

$$\forall y\,(y \in F_x \Rightarrow I(x) \leq y). \tag{3.939}$$

Recalling $h : X \to Y$ and the assumption $x \in X$, we thus have that the function value $y = h(x)$ is in Y. In view of the assumption $h \in A$, this shows that the existential sentence $\exists f\,(f \in A \wedge y = f(x))$ is true, which then implies together with $[h(x) =]\ y \in Y$ that $[h(x) =]\ y \in F_x$ holds, according to (3.929). Thus, (3.938) and (3.939) give the desired inequalities $y \leq S(x)$ as well as $I(x) \leq y$. As x was arbitrary, we may therefore conclude that the universal sentences (3.936) and (3.937) are true, which in turn imply $h \preceq S$ as well as $I \preceq h$, as desired. Because h was arbitrary as well, we may now further conclude that the universal sentences (3.934) and (3.935) also hold, so that S is indeed an upper and I a lower bound for A with respect to $\preceq$.

To prove that S is the least upper and I the greatest lower bound for A, we apply the Characterization of the supremum & infimum and let S', I' be arbitrary such that S' is an upper and I' a lower bound for A with respect to $\preceq$, so that the universal sentences

$$\forall h\,(h \in A \Rightarrow h \preceq S'), \tag{3.940}$$

$$\forall h\,(h \in A \Rightarrow I' \preceq h), \tag{3.941}$$

hold. We need to show that $S \preceq S'$ as well as $I' \preceq I$ follow to be true, which inequalities we may write equivalently as

$$\forall x\,(x \in X \Rightarrow S(x) \leq S'(x)), \tag{3.942}$$

$$\forall x\,(x \in X \Rightarrow I'(x) \leq I(x)). \tag{3.943}$$

Letting now x be arbitrary and assuming $x \in X$ to be true, we obtain with (3.930) – (3.931) $S(x) = \sup^{\leq} F_x$ and $I(x) = \inf^{\leq} F_x$. We now verify that $S'(x)$ is an upper and $I'(x)$ a lower bound for F_x with respect to $\leq$, i.e.

$$\forall y\,(y \in F_x \Rightarrow y \leq S'(x)), \tag{3.944}$$

$$\forall y\,(y \in F_x \Rightarrow I'(x) \leq y). \tag{3.945}$$

We let y be arbitrary and assume $y \in F_x$ to be true, which implies with (3.929) $y \in Y$ and moreover that there exists an element in A, say $\bar{f}$, with $y = \bar{f}(x)$. Here, $\bar{f} \in A$ implies with (3.940) and (3.941) the inequalities $\bar{f} \preceq S'$ and $I' \preceq \bar{f}$, so that the universal sentences

$$\forall x\,(x \in X \Rightarrow \bar{f}(x) \leq S'(x))$$

$$\forall x\,(x \in X \Rightarrow I'(x) \leq \bar{f}(x))$$

are true. Consequently, the assumed $x \in X$ implies $[y =]\ \bar{f}(x) \leq S'(x)$ as well as $I'(x) \leq \bar{f}(x)\ [= y]$. We thus obtained the desired consequents in (3.944) and (3.945), and since y was arbitrary, we may therefore conclude that the universal sentences (3.944) – (3.945) are true. Thus, $S'(x)$ is indeed an upper and $I'(x)$ a lower bound for F_x with respect to $\leq$. We already established $S(x)$ as the supremum and $I(x)$ as the infimum of F_x (with respect to $\leq$), so that the Characterization of the supremum & infimum yields the inequalities $S(x) \leq S'(x)$ as well as $I'(x) \leq I(x)$, as desired. As x was arbitrary, we may infer from these findings the truth of the universal sentences (3.942) – (3.943). These in turn imply $S \preceq S'$ as well as $I' \preceq I$, and because S', I' are arbitrary here, we see that the upper bound S for A is the least one and that the lower bound I for A is the greatest one (with respect to $\preceq$).

Recalling that S and I are elements of Y^X, we thus established the existential sentence in (3.927). Since A was arbitrary, we may therefore conclude that the universal sentence (3.927) holds, so that the partially ordered set $(Y^X, \preceq)$ is a complete lattice by definition. Because X, Y and $\leq$ were initially arbitrary sets, we may now finally conclude that the proposition holds. □

Theorem 3.254 (Generation of lattices of functions). *For any set X and any lattice $(Y, \leq)$, it is true that the partially ordered set $(Y^X, \preceq)$ is itself a lattice.*

Exercise 3.111. Prove Theorem 3.254.

(Hint: Carry out a similar proof as for Theorem 3.254; here, it is not necessary to apply Function definition by replacement, because one may utilize directly the definition of a pair.)

Definition 3.62 (Supremum & infimum of a function). For any sets X and Y, any partial ordering $\leq$ of Y and any function $f : X \to Y$, we say that

(1) an element S in Y is the supremum f iff S is the supremum of the range of f.

(2) an element I in Y is the infimum f iff I is the infimum of the range of f.

Notation 3.10. For any partially ordered set $(Y, \leq_Y)$ and any sequence $f = (a_n)_{n \in \mathbb{N}}$ in Y such that

(1) the supremum of the range of $(a_n)_{n\in\mathbb{N}}$ exists, we also write

$$\sup_{n\in\mathbb{N}} a_n = \overset{\leq_Y}{\sup_{n\in\mathbb{N}}} a_n = \overset{\leq_Y}{\sup} \operatorname{ran}(f) = \sup \operatorname{ran}(f). \tag{3.946}$$

(2) the infimum of the range of $(a_n)_{n\in\mathbb{N}}$ exists, we also write

$$\inf_{n\in\mathbb{N}} a_n = \overset{\leq_Y}{\inf_{n\in\mathbb{N}}} a_n = \overset{\leq_Y}{\inf} \operatorname{ran}(f) = \inf \operatorname{ran}(f). \tag{3.947}$$

Theorem 3.255 (Characterization of the supremum & of the infimum of a sequence of functions). *For any sets X and Y, any reflexive partial ordering $\leq$ of Y, any sequence $f = (f_n)_{n\in\mathbb{N}_+}$ of functions from X to Y and any function g from X to Y, it is true that*

a) g is the supremum of the sequence $f = (f_n)_{n\in\mathbb{N}_+}$ with respect to $\preceq$ iff $g(x)$ is the supremum of the sequence $f^{(x)} = (f_n(x))_{n\in\mathbb{N}_+}$ with respect to $\leq$ for any $x \in X$, i.e.

$$g = \overset{\preceq}{\sup} \operatorname{ran}(f) \;\Leftrightarrow\; \forall x\, (x \in X \Rightarrow g(x) = \overset{\leq}{\sup} \operatorname{ran}(f^{(x)})). \tag{3.948}$$

b) g is the infimum of $f = (f_n)_{n\in\mathbb{N}_+}$ with respect to $\preceq$ iff $g(x)$ is the infimum of $f^{(x)} = (f_n(x))_{n\in\mathbb{N}_+}$ with respect to $\leq$ for any $x \in X$, i.e.

$$g = \overset{\preceq}{\inf} \operatorname{ran}(f) \;\Leftrightarrow\; \forall x\, (x \in X \Rightarrow g(x) = \overset{\leq}{\inf} \operatorname{ran}(f^{(x)})). \tag{3.949}$$

Proof. We let X, Y, $\leq$, f and g be arbitrary sets, we assume $(Y, \leq)$ to be a partially ordered set, $f = (f_n)_{n \in \mathbb{N}_+}$ to be a sequence in Y^X, and g to be an element of Y^X.

To prove the first part ('$\Rightarrow$') of the equivalence in a), we assume that $g = \sup^{\preceq} \mathrm{ran}(f)$ is true, so that g as a supremum is an upper bound for (the range of) f, which thus satisfies

$$\forall g' \, (g' \text{ is an upper bound for } \mathrm{ran}(f) \Rightarrow g \preceq g'). \tag{3.950}$$

We now prove the desired universal sentence

$$\forall x \, (x \in X \Rightarrow g(x) = \overset{\leq}{\sup} \, \mathrm{ran}(f^{(x)})), \tag{3.951}$$

letting $\bar{x}$ be arbitrary and assuming $\bar{x} \in X$ to be true. Then, since we found g to be an upper bound for $\mathrm{ran}(f)$, it follows with the Characterization of upper bounds for the range of a sequence of functions in particular that $g(\bar{x})$ is an upper bound for the sequence $f^{(\bar{x})}$. To complete the proof that $g(\bar{x})$ is the supremum of $f^{(\bar{x})}$, we take an arbitrary upper bound S' for $f^{(\bar{x})}$ and show that $g(\bar{x}) \leq S'$ follows to be true. For this purpose, we construct a function $\bar{g}' : X \to Y$ such that $\bar{g}'(\bar{x}) = S'$ and such that $\bar{g}'(x)$ is some upper bound for the sequence $f^{(x)} = (f_n(x))_{n \in \mathbb{N}_+}$ for all $x \neq \bar{x}$ (which evidently implies that $\bar{g}'$ is an upper bound for f). To do this, we apply first Function definition by replacement to establish the unique existence of a function F with domain X satisfying

$$\begin{aligned} \forall x \, (x \in X \Rightarrow [(x = \bar{x} \Rightarrow F(x) = \{S'\}) \\ \wedge \, (x \neq \bar{x} \Rightarrow F(x) \text{ consists of all upper bounds for } \mathrm{ran}(f^{(x)}))]), \end{aligned} \tag{3.952}$$

and we prove for this purpose

$$\begin{aligned} \forall x \, (x \in X \Rightarrow \exists! U \, ([(x = \bar{x} \Rightarrow U = \{S'\}) \\ \wedge \, (x \neq \bar{x} \Rightarrow U \text{ consists of all upper bounds for } \mathrm{ran}(f^{(x)}))])). \end{aligned} \tag{3.953}$$

We let x be arbitrary, assume $x \in X$ to be true, and begin with the existential part, which we prove by considering the two cases based on the disjunction $x = \bar{x} \vee x \neq \bar{x}$ (which is true according to the Law of the Excluded Middle). In the first case of $x = \bar{x}$, replacing the variable U by the constant $\{S'\}$ yields the true implication

$$x = \bar{x} \Rightarrow \{S'\} = \{S'\}$$

(which has a true antecedent and consequent) and the true implication

$$x \neq \bar{x} \Rightarrow \{S'\} \text{ consists of all upper bounds for } \mathrm{ran}(f^{(x)})$$

(being based on a false antecedent); thus, the existential part holds for the first case. In the second case $x \neq \bar{x}$, we see that $f^{(x)}$ is a sequence in Y due to Proposition 3.231, so that $\mathrm{ran}(f^{(x)}) \subseteq Y$ holds by definition of a codomain; since $(Y, \leq)$ is partially ordered, we then observe in light of Exercise 3.41a) that there exists a (unique) set $\bar{U}$ consisting of all upper bounds for $\mathrm{ran}(f^{(x)})$ (with respect to $\leq$). Thus, the implication

$$x = \bar{x} \Rightarrow \bar{U} = \{S'\}$$

(which has a false antecedent) and the implication

$$x \neq \bar{x} \Rightarrow \bar{U} \text{ consists of all upper bounds for } \mathrm{ran}(f^{(x)})$$

are true, so that the existential part holds also in the second case. Regarding the uniqueness part, we take an arbitrary constant $\bar{U}$ satisfying the implication

$$\begin{aligned}&(x = \bar{x} \Rightarrow \bar{U} = \{S'\})\\ &\quad \wedge\ (x \neq \bar{x} \Rightarrow \bar{U} \text{ consists of all upper bounds for } \mathrm{ran}(f^{(x)}))\end{aligned}$$

and an arbitrary constant $\bar{U}'$ satisfying the implication

$$\begin{aligned}&(x = \bar{x} \Rightarrow \bar{U}' = \{S'\})\\ &\quad \wedge\ (x \neq \bar{x} \Rightarrow \bar{U}' \text{ consists of all upper bounds for } \mathrm{ran}(f^{(x)})),\end{aligned}$$

and we show that $\bar{U} = \bar{U}'$ follows to be true. Then, the first case $x = \bar{x}$ implies $\bar{U} = \{S'\}$ as well as $\bar{U}' = \{S'\}$, which equations yield via substitution $\bar{U} = \bar{U}'$, as desired. The other case $x \neq \bar{x}$ implies that $\bar{U}$ and $\bar{U}'$ both consist of all upper bounds for $\mathrm{ran}(f^{(x)})$, which also gives the desired $\bar{U} = \bar{U}'$ because the set of all upper bounds for $\mathrm{ran}(f^{(x)})$ is unique (again according to Exercise 3.41a)). We thus established also the uniqueness part for both cases, and as x was arbitrary, we may therefore conclude that the universal sentence (3.953) is true, which then implies that there is a unique function F with domain X such that (3.952) holds. Since the range of F is a subset of itself (according to Proposition 2.4), we have that $\mathrm{ran}(F)$ is a codomain of F, so that

$$F : X \to \mathrm{ran}(F) \tag{3.954}$$

holds. Let us now prove that $\emptyset \notin \mathrm{ran}(F)$ holds, by verifying the equivalent universal sentence (according to (2.5))

$$\forall U\, (U \in \mathrm{ran}(F) \Rightarrow U \neq \emptyset). \tag{3.955}$$

We let U be arbitrary and assume $U \in \mathrm{ran}(F)$, so that there is (by definition of a range) a constant, say $\bar{x}$, with $(\bar{x}, U) \in F$. Because F is a function with domain X, we obtain $U = F(\bar{x})$ and $\bar{x} \in X$. In view of (3.952), it then follows from these findings that U consists of all upper bounds for $f^{(\bar{x})}$. Since g is an upper bound for f, it follows with the Characterization of upper bounds for a sequence of functions in particular that $g(\bar{x})$ is an upper bound for the sequence $f^{(\bar{x})}$, so that $g(\bar{x}) \in U$ is true. Thus, there exists an element in U, so that the desired negation $U \neq \emptyset$ holds according to (2.42). As U was arbitrary, we may now conclude that (3.955) is indeed true. Because this universal sentence implies $\emptyset \notin \mathrm{ran}(F)$, we may now apply the Axiom of Choice to infer from this negation that there exists a function from $\mathrm{ran}(F)$ to the union of that range, say $\bar{G} : \mathrm{ran}(F) \to \bigcup \mathrm{ran}(F)$, such that

$$\forall U \,(U \in \mathrm{ran}(F) \Rightarrow \bar{G}(U) \in U) \tag{3.956}$$

holds. We may now show that Y is also a codomain of $\bar{G}$. For this purpose, we establish $\bigcup \mathrm{ran}(F) \subseteq Y$ by verifying the equivalent

$$\forall u \,(u \in \bigcup \mathrm{ran}(F) \Rightarrow u \in Y). \tag{3.957}$$

We let u be arbitrary and assume $u \in \bigcup \mathrm{ran}(F)$. By definition of the union of a set system, there exists then an element of $\mathrm{ran}(F)$, say $\bar{U}$, such that $u \in \bar{U}$ is true. Here, $\bar{U} \in \mathrm{ran}(F)$ evidently implies the existence of a particular element $\bar{x}$ of the domain X of F such that $(\bar{x}, \bar{U}) \in F$ holds. We may write for the latter also $[u \in]\ \bar{U} = F(\bar{x})$, which shows in light of (3.952) that u is an upper bound for $\mathrm{ran}(f^{(\bar{x})})$ (with respect to the partial ordering $\leq$ of Y). Thus, $u \in Y$ holds by definition of an upper bound, as desired, and as u was arbitrary, we may therefore conclude that the universal sentence (3.957) is true. Consequently, we obtain the inclusion $\bigcup \mathrm{ran}(F) \subseteq Y$ with the definition of a subset, and because the inclusion $\mathrm{ran}(\bar{G}) \subseteq \bigcup \mathrm{ran}(F)$ is also true by definition of a codomain, the transitivity of $\subseteq$ yields $\mathrm{ran}(\bar{G}) \subseteq Y$. Thus, Y is indeed a codomain of $\bar{G}$, so that

$$\bar{G} : \mathrm{ran}(F) \to Y. \tag{3.958}$$

In view of (3.954) and (3.958), the composition $\bar{g}' = \bar{G} \circ F$ follows then to be a function from X to Y according to Proposition 3.178, i.e. $\bar{g}' : X \to Y$. Let us quickly check that $\bar{g}'$ has all of the desired properties. Letting $x \in X$ be arbitrary and considering the case of $x = \bar{x}$, this function yields

$$[\bar{g}'(\bar{x}) =]\ \bar{G}(F(\bar{x})) = \bar{G}(\{S'\}) \in \{S'\}$$

according to (3.952) and (3.956), and therefore indeed $\bar{g}'(\bar{x}) = S'$ with (2.169). In the other case of $x \neq \bar{x}$, we have

$$[\bar{g}'(x) =]\ \bar{G}(F(x)) \in F(x)$$

where $F(x)$ consists of all upper bounds for $\mathrm{ran}(f^{(x)})$, as specified in (3.952); thus, $\bar{g}'(x)$ is indeed an upper bound for the sequence $f^{(x)} = (f_n(x))_{n\in\mathbb{N}_+}$ for any $x \neq \bar{x}$. Having accomplished the task of establishing the upper bound $\bar{g}'$ for $\mathrm{ran}(f)$, we may now apply (3.950) to infer the truth of $g \preceq \bar{g}'$, which yields in particular $g(\bar{x}) \leq \bar{g}'(\bar{x})$ $[= S']$. This finding completes the proof of $g(\bar{x}) \leq S'$, and as S' was an arbitrary upper bound for $f^{(\bar{x})}$, we may conclude that $g(\bar{x})$ is the supremum of $f^{(\bar{x})}$. Because $\bar{x}$ was also arbitrary, we may furthermore conclude that the universal sentence (3.951) holds, completing the proof of the first part of the equivalence in a).

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume that $g(x)$ is the supremum of $f^{(x)}$ for all $x \in X$. Thus, $g(x)$ is an upper bound for $f^{(x)}$ for all $x \in X$, so that g is evidently an upper bound for f. To demonstrate that g is the least upper bound, we let g' be an arbitrary upper bound for f and show that $g \preceq g'$ follows to be true. To establish the latter, we use (3.903) and let x be arbitrary in X. Now, since g' is an upper bound for f, we have that $g'(x)$ is an upper bound for $f^{(x)}$; as $g(x)$ is the least upper bound for that sequence, we see that $g(x) \leq g'(x)$ holds. Because x is arbitrary, the preceding inequality is then true for all $x \in X$, so that $g \preceq g'$ holds indeed. This completes the proof that g is the supremum of the sequence f, which means that the second part of the proposed equivalence is true as well.

Since $X, Y, \leq, f$ and g were initially arbitrary, we may therefore conclude that Part a) of the stated theorem holds. □

Notation 3.11. In case the supremum/infimum of the range of a sequence $f = (f_n)_{n\in\mathbb{N}_+}$ of functions from X to Y exists, we write respectively

$$\sup_{n\in\mathbb{N}_+} f_n \,\mathrm{pointwise} = \overset{\preceq}{\sup}\,\mathrm{ran}(f) \tag{3.959}$$

and

$$\inf_{n\in\mathbb{N}_+} f_n \,\mathrm{pointwise} = \overset{\preceq}{\inf}\,\mathrm{ran}(f), \tag{3.960}$$

and we speak of the *pointwise supremum/pointwise infimum* of (the range of) f.

3.4.8. Monotone functions, order-embeddings, and order-isomorphisms

In the following we will use irreflexive partial orderings alongside their induced reflexive counterparts.

Definition 3.63 (Increasing / order-preserving / isotone function, strictly increasing function, decreasing / order-reversing / antitone function, strictly decreasing function, monotone function, strictly monotone function). For any partially ordered sets $(X, <_X)$ and $(Y, <_Y)$ and for any function $f : X \to Y$, we say that

(1) f is *increasing* or *order-preserving* or *isotone* (with respect to $\leq_Y$) iff

$$\forall x, y\,([x, y \in X \,\wedge\, x <_X y] \Rightarrow f(x) \leq_Y f(y)). \tag{3.961}$$

(2) f is *strictly increasing* (with respect to $<_Y$) iff

$$\forall x, y\,([x, y \in X \,\wedge\, x <_X y] \Rightarrow f(x) <_Y f(y)). \tag{3.962}$$

(3) f is *decreasing/order-reversing/antitone* (with respect to $\leq_Y$) iff

$$\forall x, y\,([x, y \in X \,\wedge\, x <_X y] \Rightarrow f(x) \geq_Y f(y)). \tag{3.963}$$

(4) f is *strictly decreasing* (with respect to $<_Y$) iff

$$\forall x, y\,([x, y \in X \,\wedge\, x <_X y] \Rightarrow f(x) >_Y f(y)). \tag{3.964}$$

(5) f is *monotone* iff f is increasing or decreasing.

(6) f is *strictly monotone* iff f is strictly increasing or strictly decreasing.

Note 3.35. We will use the terms *isotone* and *antitone* only in cases of set systems which are partially ordered by inclusion according to Theorem 3.64.

Proposition 3.256. *For any partially ordered sets $(X, <_X)$, $(Y, <_X)$ and for any element $c \in Y$, it is true that the constant function $g_c : X \to Y$ is increasing.*

Proof. Letting X, $<_X$, Y, $<_Y$ and c be arbitrary such that $(X, <_X)$ and $(Y, <_X)$ are partially ordered sets and such that $c \in Y$ holds, we now show that the constant function g_c on X satisfies (3.961). For this purpose, we take arbitrary x, y and assume the conjunction of $x, y \in X$ and $x <_X y$ to be true. We then obtain with Corollary 3.154 the equations $g_c(x) = c$ and $g_c(y) = c$, so that substitution yields $g_c(x) = g_c(y)$. Consequently, the disjunction $g_c(x) <_Y g_c(y) \vee g_c(x) = g_c(y)$ is also true, which in turn gives $g_c(x) \leq_Y g_c(y)$ by definition of an induced reflexive partial ordering. Since x and y are arbitrary, we may infer from this finding that the constant function g_c is indeed increasing, by definition. As X, $<_X$, Y, $<_Y$ and c were initially arbitrary, we may therefore conclude that the proposed universal sentence holds. □

Exercise 3.112. Prove for any partially ordered sets $(X, <_X)$, $(Y, <_X)$ and for any element $c \in Y$ that the constant function $g_c : X \to Y$ is decreasing.

Exercise 3.113. Verify for any partially ordered set $(Y, <_X)$ that the empty function $\emptyset : \emptyset \to Y$ is increasing, strictly increasing, decreasing, strictly decreasing, monotone, and strictly monotone.

(Hint: Apply (2.40) with Proposition 3.151 and Corollary 3.66.)

There exist convenient alternative characterizations of increasing and decreasing functions.

Proposition 3.257. *For any partially ordered sets* $(X, \leq_X)$ *and* $(Y, \leq_Y)$ *and for any function* $f : X \to Y$*, it is true that* f *is increasing iff*

$$\forall x, y\,([x, y \in X \;\wedge\; x \leq_X y] \Rightarrow f(x) \leq_Y f(y)). \tag{3.965}$$

Proof. We let X, Y, $<_X$, $\leq_X$, $<_Y$, $\leq_Y$ and f be arbitrary sets, assume that $<_X$ is an irreflexive partial ordering and that $\leq_X$ is a reflexive partial ordering of X inducing each other, assume moreover that $<_Y$ is an irreflexive partial ordering and that $\leq_Y$ is a reflexive partial ordering of Y inducing each other, and we also assume that f is a function from X to Y.

To prove the first part ('$\Rightarrow$') of the proposed equivalence, we assume that f is increasing, i.e. that (3.961) holds. To show that this implies (3.965), we let x and y be arbitrary and assume $x, y \in X$ as well as $x \leq_X y$ to be true. The latter assumption implies with Theorem 3.81 (or Theorem 3.86) the truth of the disjunction $x <_X y \vee x = y$. On the one hand, if $x <_X y$ holds, then the conjunction of this and the assumption $x, y \in X$ implies the desired $f(x) \leq_Y f(y)$ with the assumption (3.961). On the other hand, if $x = y$ is true, then the assumed $x, y \in X$ $[= \mathrm{dom}(f)]$ implies together with $x = y$ the truth of $f(x) = f(y)$ because of (3.526). Consequently, the disjunction $f(x) <_Y f(y) \vee f(x) = f(y)$ is also true (irrespective of the truth value of $f(x) <_Y f(y)$), which gives the desired $f(x) \leq_Y f(y)$ again with Theorem 3.81 (or Theorem 3.86). We thus showed that $x, y \in X$ and $x \leq_X y$ imply $f(x) \leq_Y f(y)$, and as x and y are arbitrary, we may therefore conclude that (3.965) holds, proving the first part of the proposed equivalence.

To prove the second part ('$\Leftarrow$'), we now assume (3.965) to be true and demonstrate that (3.961) follows to be true. For this purpose, we let x and y be arbitrary, assume $x, y \in X$ and $x <_X y$ to hold, and apply the arguments used in the proof of '$\Rightarrow$'. To begin with, the assumed inequality $x <_X y$ implies the disjunction $x <_X y \vee x = y$ (no matter if $x = y$ is true or false), and therefore $x \leq_X y$. Then, the conjunction of $x, y \in X$ and $x \leq_X y$ implies the desired $f(x) \leq_Y f(y)$ with (3.965). As x and y are arbitrary, it follows that (3.961) holds, so that f is increasing by definition. Thus, the proof of the equivalence is complete.

Since X, Y, $<_X$, $\leq_X$, $<_Y$, $\leq_Y$ and f were initially arbitrary sets, we may finally conclude that the proposition is true. $\square$

Exercise 3.114. Show for any partially ordered sets $(X, <_X)$ and $(Y, <_Y)$ that a function $f : X \to Y$ is decreasing iff

$$\forall x, y\,([x, y \in X \wedge x \leq_X y] \Rightarrow f(x) \geq_Y f(y)). \tag{3.966}$$

The expectation that a strictly increasing/decreasing/monotone function should be the special case of an increasing/decreasing/monotone function is confirmed straightforwardly.

Exercise 3.115. Verify the following implications for any partially ordered sets $(X, <_X)$, $(Y, <_Y)$ and for any function $f : X \to Y$.

a) If f is strictly increasing, then f is increasing.

b) If f is strictly decreasing, then f is decreasing.

c) If f is strictly monotone, then f is monotone.

Exercise 3.116. Prove for any partially ordered sets $(X, <_X)$ and $(Y, <_Y)$, for any function $f : X \to Y$ and for any set $A \subseteq X$ that

a) the restriction of f to A is increasing if f is increasing, i.e.

$$\begin{aligned} &\forall x, y\,([x, y \in X \wedge x <_X y] \Rightarrow f(x) \leq_Y f(y)) \\ &\quad \Rightarrow \forall x, y\,([x, y \in A \wedge x <_X y] \Rightarrow f \restriction A(x) \leq_Y f \restriction A(y)). \end{aligned} \tag{3.967}$$

b) the restriction of f to A is strictly increasing if f is strictly increasing, i.e.

$$\begin{aligned} &\forall x, y\,([x, y \in X \wedge x <_X y] \Rightarrow f(x) <_Y f(y)) \\ &\quad \Rightarrow \forall x, y\,([x, y \in A \wedge x <_X y] \Rightarrow f \restriction A(x) <_Y f \restriction A(y)). \end{aligned} \tag{3.968}$$

(Hint: Use (3.567).)

Definition 3.64 (Order-embedding, order-isomorphism, order-isomorphic partially ordered sets). For any posets $(X, \leq_X)$, $(Y, \leq_Y)$ and for any function $f : X \to Y$, we say that

(1) f is an *order-embedding* from $(X, \leq_X)$ to $(Y, \leq_Y)$, symbolically

$$f : (X, \leq_X) \hookrightarrow (Y, \leq_Y), \tag{3.969}$$

if, and only if,

$$\forall x, y \, (x, y \in X \Rightarrow [x \leq_X y \Leftrightarrow f(x) \leq_Y f(y)]). \tag{3.970}$$

(2) f is an *order-isomorphism* from $(X, \leq_X)$ to $(Y, \leq_Y)$, symbolically

$$f : (X, \leq_X) \rightleftarrows (Y, \leq_Y), \tag{3.971}$$

iff f is a surjection and an order-embedding. Then, we say that $(X, \leq_X)$ and $(Y, \leq_Y)$ are *order-isomorphic* iff there exists an order-isomorphism from $(X, \leq_X)$ to $(Y, \leq_Y)$.

We now verify that an order-embedding is indeed an injection, as suggested by the symbol '$\hookrightarrow$' in (3.969).

Proposition 3.258. *For any order-embedding $f : (X, \leq_X) \hookrightarrow (Y, \leq_Y)$ it is true that f is an increasing injection from X to Y.*

Proof. Letting X, Y, $\leq_X$, $<_X$, $\leq_Y$, $<_Y$ and f be arbitrary sets, we assume that $\leq_X$ is a reflexive and $<_X$ an irreflexive partial ordering of X inducing each other, assume furthermore that $\leq_Y$ is a reflexive and $<_Y$ an irreflexive partial ordering of Y inducing each other, and assume in addition that f is an order-embedding from $(X, \leq_X)$ to $(Y, \leq_Y)$. To show that f is an injection from X to Y, we verify the defining property (3.615). To do this, we let x and x' be arbitrary and assume both $x, x' \in X$ and $f(x) = f(x')$ to be true. This equation implies the disjunctions

$$f(x) <_Y f(x') \lor f(x) = f(x')$$
$$f(x') <_Y f(x) \lor f(x') = f(x)$$

(irrespective of the truth values of $f(x) <_Y f(x')$ and $f(x') <_Y f(x)$, respectively) and therefore the inequalities $f(x) \leq_Y f(x')$ and $f(x') \leq_Y f(x)$ with Theorem 3.81 (or Theorem 3.86). Since f was assumed to be an order-embedding from $(X, <_X)$ to $(Y, <_Y)$, these two inequalities imply, respectively, $x \leq_X x'$ and $x' \leq_X x$ according to (3.970). Then, the conjunction of these two inequalities further implies $x = x'$ with the fact that the reflexive partial ordering $\leq_X$ is antisymmetric. Because x and x' are arbitrary, we may therefore conclude that f satisfies (3.615), so that f is an injection.

To show that f is in addition increasing, we verify that f satisfies (3.965), letting $x, y \in X$ be arbitrary with $x \leq_X y$. Since f is an order-embedding from $(X, <_X)$ to $(Y, <_Y)$, it follows from $x, y \in X$ that the equivalence $x \leq_X y \Leftrightarrow f(x) \leq_Y f(y)$ is true, so that the assumed $x \leq_X y$ implies the desired $f(x) \leq_Y f(y)$. Because x and y are arbitrary, we may then infer from this that f satisfies (3.965), so that f is increasing.

As the sets X, Y, $\leq_X$, $<_X$, $\leq_Y$, $<_Y$ and f were arbitrary, it follows that the proposed sentence holds, as claimed. □

Combining this finding with the fact that an order-isomorphism is a surjection by definition, we see that an order-isomorphism is a bijection, so that the use of the symbol '$\rightleftarrows$' in (3.971) is justified.

Corollary 3.259. *For any order-isomorphism $f : (X, \leq_X) \rightleftarrows (Y, \leq_Y)$ it is true that f is an increasing bijection from X to Y.*

In cases of totally or linearly ordered sets it is conversely also possible to establish an increasing in-/bijection as an order-embedding/-isomorphism.

Proposition 3.260. *For any totally ordered sets $(X, \leq_X)$ and $(Y, \leq_Y)$ and for any function $f : X \to Y$, it is true that f is an order-embedding from $(X, \leq_X)$ to $(Y, \leq_Y)$ if, and only if, f is an increasing injection.*

Proof. We let X, Y, $\leq_X$, $<_X$, $\leq_Y$, $<_Y$ and f be arbitrary sets, assume that $\leq_X$ is a total and $<_X$ a linear ordering of X inducing each other, assume also that $\leq_Y$ is a total and $<_Y$ a linear ordering of Y inducing each other, and assume furthermore that f is a function from X to Y.

To prove the first part ('$\Rightarrow$') of the proposed equivalence, we assume that f is an order-embedding from $(X, \leq_X)$ to $(Y, \leq_Y)$. Then, since the totally ordered sets $(X, \leq_X)$ and $(Y, \leq_Y)$ are in particular partially ordered, we may apply Proposition 3.258 to infer that f is an increasing injection from X to Y.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume f to be an increasing injection and show that this implies that f is also an order-embedding from $(X, \leq_X)$ to $(Y, \leq_Y)$. For this purpose, we verify that f satisfies

$$\forall x, y\, (x, y \in X \Rightarrow [x \leq_X y \Leftrightarrow f(x) \leq_Y f(y)]) \tag{3.972}$$

letting x and y be arbitrary in X.

Regarding the first part ('$\Rightarrow$') of the equivalence in (3.972), we assume $x \leq_X y$, so that the disjunction $x <_X y \vee x = y$ holds with Theorem 3.81 (or Theorem 3.86). If $x <_X y$ is true, then we obtain the desired $f(x) \leq_Y f(y)$ with the assumption that f is increasing. If $x = y$ is true, then (3.526) yields $f(x) = f(y)$, so that the disjunction $f(x) <_Y f(y) \vee f(x) = f(y)$ also holds, and consequently $f(x) \leq_Y f(y)$ (using again one of the previously mentioned theorems). We thus showed that $x \leq_X y$ implies $f(x) \leq_Y f(y)$, which completes the proof of the first part of the equivalence in (3.970).

We now prove the second part ('$\Leftarrow$') of the equivalence by contradiction, assuming $f(x) \leq_Y f(y)$ and $\neg x \leq_X y$ to be both true. The latter implies $y <_X x$ with the Negation Formula for $\leq$, so that the disjunction $y <_X x \vee y = x$ also holds (regardless of the truth value of $y = x$). Evidently, this disjunction gives $y \leq_X x$, which then further implies $f(y) \leq_Y f(x)$ with the previously established first part of the equivalence in (3.972). Now, the conjunction of this and the assumed $f(x) \leq_Y f(y)$ in turn implies $f(y) = f(x)$ with the antisymmetry of the total ordering $\leq_Y$, and this equation yields $y = x$ with the definition of an injection. Thus, $y = x$ and $y <_X x$ are both true, which contradicts the fact that the linear ordering $<_X$ is comparable.

This completes the proof of the equivalence in (3.972), and since x and y are arbitrary, the universal sentence (3.972) follows then to be true. Thus, f is an order-embedding (by definition) from $(X, \leq_X)$ to $(Y, \leq_Y)$, which finding completes the proof of the proposed equivalence. Since X, Y, $\leq_X$, $<_X$, $\leq_Y$, $<_Y$ and f were arbitrary sets, we may finally conclude that the proposition holds. □

If the injectivity condition is replaced by bijectivity in the preceding proposition, the order-embedding turns into an order-isomorphism, by definition.

Corollary 3.261. *For any totally ordered sets $(X, \leq_X)$, $(Y, \leq_Y)$ and for any function $f : X \to Y$, it is true that f is an order-isomorphism from $(X, \leq_X)$ to $(Y, \leq_Y)$ if, and only if, f is an increasing bijection.*

Proposition 3.262. *The following implications are true for any complete lattices $(X, \leq_X)$ and $(Y, \leq_Y)$ and any function $f : X \to Y$.*

a) If f is an increasing function from X to Y, then

$$\forall A\,(A \subseteq X \Rightarrow \sup f[A] \leq_Y f(\sup A)). \tag{3.973}$$

b) If f is an order-isomorphism from $(X, \leq_X)$ to $(Y, \leq_Y)$, then

$$\forall A\,(A \subseteq X \Rightarrow \sup f[A] = f(\sup A)). \tag{3.974}$$

Proof. We let X, Y, $\leq_X$, $\leq_Y$, f be arbitrary sets such that $(X, \leq_X)$ and $(Y, \leq_Y)$ are complete lattices and such that f is a function from X to Y.

Concerning a), we assume that f is increasing, and then also that A is an arbitrary subset of X. Since $(X, \leq_X)$ is a complete lattice, $\sup A$ exists in X, and this supremum is by definition an upper bound for A, so that

$$\forall x\,(x \in A \Rightarrow x \leq_X \sup A) \tag{3.975}$$

holds. We now show that $f(\sup A)$ is an upper bound for $f[A]$, i.e. that

$$\forall y\,(y \in f[A] \Rightarrow y \leq_Y f(\sup A)) \tag{3.976}$$

is true. For this purpose, we let y be arbitrary and assume $y \in f[A]$ to be true, which means by definition of a direct image that $y \in \operatorname{ran}(f \upharpoonright A)$ holds. By definition of a range, there then exists an element, say $\bar{x}$, such that $(\bar{x}, y) \in f \upharpoonright A$ is true. Since $\operatorname{dom}(f \upharpoonright A) = A$ holds according to Proposition 3.164, it follows with the definition of a domain that $\bar{x} \in A$ holds, which further implies $\bar{x} \leq_X \sup A$ with (3.975). Since f is increasing, this inequality yields $f(\bar{x}) \leq_X f(\sup A)$ with (3.965). Now, the previously established $(\bar{x}, y) \in f \upharpoonright A$ implies also $(\bar{x}, y) \in f$ by definition of a restriction, which we may write as $y = f(\bar{x})$, so that substitution in the preceding inequality yields the desired $y \leq_Y f(\sup A)$. Because y is arbitrary, we may therefore conclude that (3.976) holds, so that $f(\sup A)$ is indeed an upper bound for the image $f[A]$. Furthermore, as f is a function with codomain Y, we have (again due to Proposition 3.164) that the restriction $f \upharpoonright A$ is also a function with codomain Y, so that $\operatorname{ran}(f \upharpoonright A) \subseteq Y$. Thus, the image $f[A] = \operatorname{ran}(f \upharpoonright A)$ is a subset of Y, and its supremum $\sup f[A]$ exists then in Y since $(Y, \leq_Y)$ is by assumption a complete lattice. Recalling that $f(\sup A)$ is an upper bound for $f[A]$, we now obtain with the definition of a supremum the inequality $\sup f[A] \leq_Y f(\sup A)$, as desired. Since A is arbitrary, it then follows that (3.973) is true, so that the proof of a) is complete.

Concerning b), we assume that f is an order-isomorphism from $(X, \leq_X)$ to $(Y, \leq_Y)$, so that f is then an increasing bijection in view of Corollary 3.261. Next, we let $A \subseteq X$ be arbitrary and prove the equation in (3.973) by showing that $f(\sup A)$ is the supremum of $f[A]$. Since f is increasing, it follows as in the proof of a) that (3.976) holds, i.e. that $f(\sup A)$ is an upper bound for $f[A]$. To prove that this is the least upper bound, we apply the definition of a supremum, letting S' be an arbitrary upper bound for $f[A]$ and showing that this implies $f(\sup A) \leq_Y S'$. By definition of an upper bound, we thus have

$$\forall y\,(y \in f[A] \Rightarrow y \leq_Y S'). \tag{3.977}$$

Recalling that f is a bijection from X to Y, it follows with 3.683d) that the inverse function f^{-1} is a bijection from Y to X. Based on this observation, we now verify that $f^{-1}(S')$ is an upper bound for A, i.e. that

$$\forall x\,(x \in A \Rightarrow x \leq_X f^{-1}(S')) \tag{3.978}$$

holds. For this purpose, we let x be arbitrary, assume $x \in A$ to be true, and recall that $A = \operatorname{dom}(f \upharpoonright A)$ holds, so that there exists by definition of a domain an element, say $\bar{y}$, such that $(x,\bar{y}) \in f \upharpoonright A$. By definition of a range, this implies $\bar{y} \in \operatorname{ran}(f \upharpoonright A)$, so that $\bar{y} \in f[A]$ holds (by definition of a direct image), and therefore $\bar{y} \leq_Y S'$ due to (3.977). Now, since $(x,\bar{y}) \in f \upharpoonright A$ also implies $(x,\bar{y}) \in f$ (by definition of a restriction) and therefore $\bar{y} = f(x)$, the preceding inequality becomes after substitution $f(x) \leq_Y S'$. As the equations

$$S' = \mathrm{id}_Y(S') = f(f^{-1}(S')) \tag{3.979}$$

hold by definition of an identity function and with (3.680), the preceding inequality yields $f(x) \leq_Y f(f^{-1}(S'))$, which then implies the desired $x \leq_X f^{-1}(S')$ with (3.970), applying the fact that the assumed order-isomorphism f is an order-embedding by definition. As x is arbitrary, we may therefore conclude that (3.978) is true, which means that $f^{-1}(S')$ is indeed an upper bound for A. Since $\sup A$ is the least upper bound for A, we obtain the inequality $\sup A \leq_X f^{-1}(S')$ with the definition of a supremum. Then, this inequality implies $f(\sup A) \leq_X f(f^{-1}(S'))$ with (3.970), and therefore $f(\sup A) \leq_X S'$ with the equations (3.979). Because S' is an arbitrary upper bound for $f[A]$, it follows now from the preceding inequality that $f(\sup A)$ is the supremum of $f[A]$, so that the equation in (3.974) holds. Since A is arbitrary, we may then further conclude that b) is true.

In the proofs of a) and b) the sets X, Y, $\leq_X$, $\leq_Y$ and f were arbitrary, so that we may finally conclude that the proposed universal sentences are true. □

Exercise 3.117. Prove the following implications for any complete lattices $(X, \leq_X)$, $(Y, \leq_Y)$ and for any function $f : X \to Y$.

a) If f is an increasing function from X to Y, then

$$\forall A\,(A \subseteq X \Rightarrow f(\inf A) \leq_Y \inf f[A]). \tag{3.980}$$

b) If f is an order-isomorphism from $(X, \leq_X)$ to $(Y, \leq_Y)$, then

$$\forall A\,(A \subseteq X \Rightarrow f(\inf A) = \inf f[A]). \tag{3.981}$$

(Hint: Proceed in analogy to the proof of Proposition 3.262.)

Part II.

Counting Data

Chapter 4.

Counting Sets

4.1. Counting Domains $(C, s, 0_C)$

We begin this chapter with a formal and general description of *counting*. For this purpose, we define a certain structure in form of an ordered triple consisting of (1) a set C whose elements may be regarded as the possible outcomes of a counting activity, (2) a function s each of whose values represents the unique possible outcome of a single counting step after having counted up to a certain element of C, and (3) an element 0_C in C which indicates that no counting (step) has been carried out yet.

Definition 4.1 (Counting domain, counting set, successor function, beginning, Peano's Axioms). For any set C, any function $s : C \to C$ and any element $0_C \in C$, we say that the ordered triple $(C, s, 0_C)$ is a *counting domain* iff

1. the range of the function s does not contain 0_C, i.e.

$$\forall n \, (n \in C \Rightarrow s(n) \neq 0_C), \tag{4.1}$$

2. the function s is an injection, i.e.

$$\forall m, n \, ([m, n \in C \, \wedge \, s(m) = s(n)] \Rightarrow m = n), \tag{4.2}$$

   and

3. any subset M of C, containing 0_C and the value of the successor function at any element of M, is identical with C, i.e.

$$\forall M \, ([M \subseteq C \, \wedge \, 0_C \in M \, \wedge \, \forall n \, (n \in M \Rightarrow s(n) \in M)] \Rightarrow M = C). \tag{4.3}$$

We then call C the *counting set*, s the *successor function*, and 0_C the *beginning* of C. Furthermore, we call the definite properties 1. – 3. *Peano's axioms*.

Theorem 4.1 (Characterization of the elements of a counting set). *The following sentence holds for any counting domain* $(C, s, 0_C)$.

$$\forall n\,(n \in C \Rightarrow [n = 0_C \ \vee\ \exists m\,(m \in C \ \wedge\ m \neq n \ \wedge\ s(m) = n)]). \tag{4.4}$$

Proof. We let C, s and 0_C be arbitrary, assume that $(C, s, 0_C)$ is a counting domain, and apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true sentence

$$\exists! M\, \forall n\,(n \in M \Leftrightarrow [n \in C \wedge (n = 0_C \vee \exists m\,(m \in C \wedge m \neq n \wedge s(m) = n))]). \tag{4.5}$$

Thus, M satisfies

$$\forall n\,(n \in M \Leftrightarrow [n \in C \ \wedge\ (n = 0_C \ \vee\ \exists m\,(m \in C \ \wedge\ m \neq n \ \wedge\ s(m) = n))]). \tag{4.6}$$

Let us observe here that $n \in M$ implies in particular $n \in C$ for any n, which means by definition of a subset

$$M \subseteq C. \tag{4.7}$$

Furthermore, the truth of the equation $n = 0_C$ implies $n \in C$ since 0_C holds by definition of a counting domain. Then, the disjunction in (4.6) is true no matter if the existential sentence involved is true or false. Consequently, the conjunction of the true $0_C \in C$ and the preceding disjunction also holds, which implies with (4.6)

$$0_C \in M. \tag{4.8}$$

Next, we verify

$$\forall n\,(n \in M \Rightarrow s(n) \in M), \tag{4.9}$$

which – together with (4.7) and (4.8) – will imply $M = C$ with Property 3 of a counting domain. To prove this universal sentence, we let n be arbitrary, and we prove the implication directly, assuming $n \in M$ to be true. As observed earlier, the latter implies $n \in C$, and $s(n) \in C$ is then also true because C is codomain of s. Let us now use the disjunction $n = 0_C \ \vee\ n \neq 0_C$, which is true according to the Law of the Excluded Middle, to prove the sentence

$$\exists m\,(m \in C \ \wedge\ m \neq s(n) \ \wedge\ s(m) = s(n)) \tag{4.10}$$

by cases. Since $n, 0_C \in C$ is true, the first case $n = 0_C$ implies $s(n) = s(0_C)$ with (3.526). Moreover, $s(n) \neq 0_C$ is also true according to Property 1 of a counting domain, so that the multiple conjunction

$$0_C \in C \ \wedge\ 0_C \neq s(n) \ \wedge\ s(0_C) = s(n)$$

evidently holds, which shows that the existential sentence (4.10) is true in the first case. Since the assumed $n \in M$ implies with (4.6) in particular

$$n = 0_C \lor \exists m\,(m \in C \land m \neq n \land s(m) = n),$$

the second case $n \neq 0_C$ shows that the first part of this disjunction is false, so that the second part part of the disjunction (i.e., the existential sentence) is true. Thus, there exists a constant, say $\bar{m}$, such that the multiple conjunction

$$\bar{m} \in C \land \bar{m} \neq n \land s(\bar{m}) = n \tag{4.11}$$

is true. This yields in particular $\bar{m} \neq n$, which then further implies $s(\bar{m}) \neq s(n)$ with (4.2) in connection with the Injection Criterion. As (4.11) implies also in particular $s(\bar{m}) = n$, it follows with the preceding inequality via substitution that $n \neq s(n)$ holds. Thus, the multiple conjunction

$$n \in C \land n \neq s(n) \land s(n) = s(n)$$

is evidently true, so that the existential sentence (4.10) holds also in the second case, completing the proof by cases. Then, the disjunction

$$s(n) = 0_C \lor \exists m\,(m \in C \land m \neq s(n) \land s(m) = s(n))$$

is also true (even though $s(n) = 0_C$ is false). Recalling the previously found $s(n) \in C$, we now see that the conjunction

$$s(n) \in C \land (s(n) = 0_C \lor \exists m\,(m \in C \land m \neq s(n) \land s(m) = s(n)))$$

holds, which in turn implies the desired consequent $s(n) \in M$ with (4.6). As n was arbitrary, we may therefore conclude that (4.9) is true. The conjunction of (4.7), (4.8) and (4.9) then implies $M = C$ with (4.3). We are now in a position to verify the proposed universal sentence. Letting $n \in C$ be arbitrary, we may apply substitution based on the preceding equation to obtain $n \in M$, which implies with (4.6) in particular

$$n = 0_C \lor \exists m\,(m \in C \land m \neq n \land s(m) = n).$$

As this is the desired consequent of the implication in (4.4), and since n was arbitrary, we may therefore conclude that (4.4) is true. Because C, s and 0_C were initially arbitrary, we may finally conclude that the theorem holds. □

Proposition 4.2. *The successor function in any counting domain $(C, s, 0_C)$ is a bijection from C to $C \setminus \{0_C\}$, i.e.*

$$s : C \rightleftarrows C \setminus \{0_C\}. \tag{4.12}$$

Proof. We let C, s and 0_C be arbitrary, assume that $(C, s, 0_C)$ is a counting domain, and prove first that the range of s is identical with $C \setminus \{0_C\}$. For this purpose, we may prove the equivalent (applying the Equality Criterion for sets)

$$\forall n\,(n \in \operatorname{ran}(s) \Leftrightarrow n \in C \setminus \{0_C\}). \tag{4.13}$$

We let n be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $n \in \operatorname{ran}(s)$ is true. This assumption implies by definition of a range that there exists an element, say $\bar{m}$, such that $(\bar{m}, n) \in s$ holds. Then, $\bar{m} \in \operatorname{dom}(s)$ holds by definition of a domain, so that we obtain $\bar{m} \in C$ by definition of s. Furthermore, $(\bar{m}, n) \in s$ means $s(\bar{m}) = n$ due to Notation 3.4, so that $s(\bar{m}) \neq 0_C$ holds because of Property 1 of a counting domain. Therefore, the preceding equation gives $n \neq 0_C$, which implies $n \notin \{0_C\}$ with (2.169). Now, since s is a function with codomain C, we have that $\operatorname{ran}(s) \subseteq C$ holds (by definition of a codomain). With this, the assumption $n \in \operatorname{ran}(s)$ implies $n \in C$ by definition of a subset. Thus, $n \in C$ and $n \notin \{0_C\}$ are both true, so that we obtain the desired $n \in C \setminus \{0_C\}$ by applying the definition of a set difference.

To prove the second part ('$\Leftarrow$') of the equivalence in (4.13), we now assume $n \in C \setminus \{0_C\}$ to be true, which evidently means that $n \in C$ and $n \notin \{0_C\}$ are both true. Since the latter implies $n \neq 0_C$ with (2.169) and the Law of Contraposition, it follows with (4.4) from $n \in C$ that there exists an element of C, say $\bar{m}$, such that $\bar{m} \neq n$ and $s(\bar{m}) = n$ hold. The latter equation means $(\bar{m}, n) \in s$, so that the desired $n \in \operatorname{ran}(s)$ holds (by definition of a range). Thus, the proof of the equivalence is complete, and as n is arbitrary, we therefore conclude that (4.13) is true, which in turn proves the equation $\operatorname{ran}(s) = C \setminus \{0_C\}$. Consequently, s is a surjection from C to $C \setminus \{0_C\}$; in view of Note 3.23, we then see that the injection $s : C \hookrightarrow C$ is also an injection from C to $C \setminus \{0_C\}$. These two findings imply that s is a bijection from C to $C \setminus \{0_C\}$. Since C, s and 0_C were arbitrary, we may now further conclude that the proposition holds. $\square$

Proposition 4.3. *For any counting domain $(C, s, 0_C)$ it is true that the successor of any element of C is different from that element, that is,*

$$\forall n\,(n \in C \Rightarrow s(n) \neq n). \tag{4.14}$$

Proof. We let C, s and 0_C be arbitrary and assume that $(C, s, 0_C)$ is a counting domain. Then, we let n also be arbitrary and prove the implication by cases. Regarding the first case, we prove the implication

$$(n \in C \land n = 0_C) \Rightarrow s(n) \neq n \tag{4.15}$$

by contradiction, assuming $n \in C$, $n = 0_C$ and $\neg s(n) \neq n$ to be true, where the latter implies $s(n) = n$ with the Double negation Law. Together with the evident fact $0_C \in C$, the assumed $n \in C$ and $n = 0_C$ imply $s(n) = s(0_C)$ because s is a function (see Corollary 3.150). Since $s(0_C) \neq 0_C$ also holds according to Property 1 of a counting domain, we obtained a contradiction, so that the proof of the implication (4.15) is complete. Regarding the second case, we now prove the corresponding implication

$$(n \in C \wedge n \neq 0_C) \Rightarrow s(n) \neq n, \tag{4.16}$$

by contradiction, assuming that $n \in C$, $n \neq 0_C$ and $\neg s(n) \neq n$ hold, so that $s(n) = n$ follows again to be true. In view of the Characterization of the elements of a counting set, the assumed $n \in C$ implies the truth of the disjunction

$$n = 0_C \vee \exists m \, (m \in C \wedge m \neq n \wedge s(m) = n), \tag{4.17}$$

whose first part $n = 0_C$ is false by virtue of the assumption $n \neq 0_C$, so that the second part (i.e., the existential sentence) is true. Thus, there exists an element, say $\bar{m}$, such that the multiple conjunction

$$\bar{m} \in C \wedge \bar{m} \neq n \wedge s(\bar{m}) = n \tag{4.18}$$

is true. The third part $s(\bar{m}) = n$ implies with the previously established $s(n) = n$ the equation $s(\bar{m}) = s(n)$ via substitution. This equation in turn implies $\bar{m} = n$ with the injectivity of s (see (4.2)), which equation is in contradiction to the true second part $\bar{m} \neq n$ of the multiple conjunction (4.18). This completes the proof of the implication (4.16) and thus the proof of the implication in (4.14) by cases. Since n, C, s and 0_C were arbitrary, the proposition follows to be true. $\square$

The following section shows that the set $\mathbb{N}$ of natural numbers is suitable for the purpose of formal counting, which is a fact we apply routinely in daily life.

4.1.1. The counting domain $(\mathbb{N}, s^+, 0)$

Lemma 4.4. *The following sentences are true regarding* $\mathbb{N}$*.*

a) There exists a unique set $\in_{\mathbb{N}}$ *consisting of all the elements* Y *in* $\mathbb{N} \times \mathbb{N}$ *such* Y *is an ordered pair formed by some natural numbers* m *and* n *where* m *is element of* n*, and this set is a binary relation on* $\mathbb{N} \times \mathbb{N}$ *satisfying*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \in_{\mathbb{N}} n \Leftrightarrow m \in n]). \tag{4.19}$$

b) Furthermore, the binary relation $\in_{\mathbb{N}}$ *is transitive, that is,*

$$\forall a, b, n\,(a, b, n \in \mathbb{N} \Rightarrow [(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n) \Rightarrow a \in_{\mathbb{N}} n]). \tag{4.20}$$

c) Moreover, the binary relation $\in_{\mathbb{N}}$ *is irreflexive, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \neg n \in_{\mathbb{N}} n). \tag{4.21}$$

Proof. Concerning a), we may apply the Axiom of Specification in connection with the Equality Criterion for sets (in analogy to the proof of Theorem 2.15) to obtain the true uniquely existential sentence

$$\exists! \in_{\mathbb{N}} \forall Y\,(Y \in \in_{\mathbb{N}} \Leftrightarrow [Y \in \mathbb{N} \times \mathbb{N} \,\wedge\, \exists m, n\,(m \in n \,\wedge\, (m, n) = Y)]).$$

Since $Y \in \in_{\mathbb{N}}$ implies in particular $Y \in \mathbb{N} \times \mathbb{N}$ for any Y, it follows by definition of a subset that $\in_{\mathbb{N}} \subseteq \mathbb{N} \times \mathbb{N}$ holds. Thus, $\in_{\mathbb{N}}$ is a binary relation on $\mathbb{N} \times \mathbb{N}$, which satisfies

$$\forall Y\,(Y \in \in_{\mathbb{N}} \Leftrightarrow [Y \in \mathbb{N} \times \mathbb{N} \,\wedge\, \exists m, n\,(m \in n \,\wedge\, (m, n) = Y)]). \tag{4.22}$$

To show that $\in_{\mathbb{N}}$ satisfies also (4.19), we let m and n be arbitrary in $\mathbb{N}$. To prove the first part ('$\Rightarrow$') of the equivalence in (4.19), we assume $m \in_{\mathbb{N}} n$, which we may also write as $(m, n) \in \in_{\mathbb{N}}$. In view of (4.22), this implies then in particular that there exist constants, say $\bar{m}$ and $\bar{n}$, such that $\bar{m} \in \bar{n}$ and $(\bar{m}, \bar{n}) = (m, n)$ hold. Since this equation yields $\bar{m} = m$ and $\bar{n} = n$ with the Equality Criterion for ordered pairs, we may apply substitutions to write $\bar{m} \in \bar{n}$ as $m \in n$, so that the proof of the first part of the equivalence in (4.19) is complete. To prove the second part ('$\Leftarrow$'), we now assume $m \in n$ to be true. Forming now the ordered pair $Y = (m, n)$, we clearly see that the existential sentence in (4.22) holds. In addition, the initial assumptions $m \in \mathbb{N}$ and $n \in \mathbb{N}$ imply with the definition of the Cartesian product of two sets $[(m, n) =]\ Y \in \mathbb{N} \times \mathbb{N}$, which in turn implies – together with the previously established existential sentence – that $[Y =]\ (m, n) \in \in_{\mathbb{N}}$ holds. Since we may write this as $m \in_{\mathbb{N}} n$, the second part of the equivalence in (4.19) also holds. Thus, the proof of the implication in (4.19) is also complete, and since m and n were arbitrary, we may therefore conclude that the universal sentence (4.19) is true.

Concerning b), to prove that the binary relation $\in_{\mathbb{N}}$ is transitive and satisfies therefore Property 2 of an irreflexive partial ordering, we verify (4.20), which we may write as

$$\forall a, b\,(a, b \in \mathbb{N} \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow [(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n) \Rightarrow a \in_{\mathbb{N}} n])), \tag{4.23}$$

by using Exercise 1.16. First we let a and b be arbitrary in $\mathbb{N}$ and prove then

$$\forall n\,(n \in \mathbb{N} \Rightarrow [(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n) \Rightarrow a \in_{\mathbb{N}} n]) \tag{4.24}$$

by mathematical induction. Considering the base case ($n = 0 = \emptyset$), we note that $b \in n$ is false by definition of $\emptyset$, so that the equivalent $b \in_{\mathbb{N}} n$ (using (4.19)) is also false. Then, the conjunction $a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n$ is false as well (irrespective of the truth value of its first part). Therefore, the implication $[a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n] \Rightarrow a \,\wedge\, n$ has a false antecedent and is thus true (for the base case $n = 0$). Concerning the induction step, we let n be arbitrary in $\mathbb{N}$ and verify

$$[(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n) \Rightarrow a \in_{\mathbb{N}} n] \Rightarrow [(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n^+) \Rightarrow a \in_{\mathbb{N}} n^+]. \tag{4.25}$$

For this purpose, we make the induction assumption

$$(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n) \Rightarrow a \in_{\mathbb{N}} n \tag{4.26}$$

and show that this implies

$$(a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n^+) \Rightarrow a \in_{\mathbb{N}} n^+. \tag{4.27}$$

To prove this implication directly, we assume $a \in_{\mathbb{N}} b$ and $b \in_{\mathbb{N}} n^+$, so that the equivalent $a \in b$ and $b \in n^+$ (applying again (4.19)) hold. The latter means by the definition of a successor $b \in n \cup \{n\}$, so that the conjunction $a \in b \wedge b \in n \cup \{n\}$ is true. We then obtain with the definition of the union of a pair

$$a \in b \,\wedge\, (b \in n \,\vee\, b \in \{n\}),$$

and then with the Distributive Law for sentences (1.44) also

$$(a \in b \,\wedge\, b \in n) \,\vee\, (a \in b \,\wedge\, b \in \{n\}). \tag{4.28}$$

Based on this true disjunction, we now prove the sentence $a \in n$ by cases. If the first part $a \in b \,\wedge\, b \in n$ holds (which we may write equivalently as $a \in_{\mathbb{N}} b \,\wedge\, b \in_{\mathbb{N}} n$ because of (4.19)), then $a \in_{\mathbb{N}} n$ follows to be true with the induction assumption (4.26), so that the equivalent $a \in n$ holds as well. If the second part $a \in b \wedge b \in \{n\}$ of the disjunction (4.28) is true, then we obtain in particular the true $b \in \{n\}$, which further implies $b = n$ with (2.169). The preceding conjunction also implies in particular $a \in b$, which then gives $a \in n$ with the true equation $b = n$, completing the proof by cases of the sentence $a \in n$. Let us now observe that $n \subseteq n^+$ holds according to (2.306); with this, we see in light of the definition of a subset that $a \in n$ implies $a \in n^+$. Then, the equivalent $a \in_{\mathbb{N}} n^+$ is also true, which finding completes the proof of the implication (4.27) and thus also the proof of the implication (4.25). Since n was arbitrary, we may therefore conclude that the induction step holds as well, so that the proof of (4.24) by mathematical induction is complete. As a and b were also arbitrary, we may finally conclude that (4.20) holds, so that $\in_{\mathbb{N}}$ is transitive.

Concerning c), we carry out a proof by mathematical induction in combination with a proof by contradiction. Regarding the base case ($n = 0 = \emptyset$), we immediately see that $\emptyset \notin \emptyset$ is true by definition of the empty set. To prove the induction step, we let n be arbitrary in $\mathbb{N}$ and verify the implication

$$n \notin n \Rightarrow n^+ \notin n^+ \tag{4.29}$$

by contradiction. To do this, we make the induction assumption

$$n \notin n \tag{4.30}$$

and further assume

$$\neg n^+ \notin n^+. \tag{4.31}$$

The latter means $\neg(\neg n^+ \in n^+)$, which implies $n^+ \in n^+$ with the Double Negation Law. Furthermore, $n^+ = n \cup \{n\}$ holds by definition of a successor, so that (4.31) gives $n^+ \in n \cup \{n\}$ via substitution. By definition of the union of a pair, this further implies $n^+ \in n \vee n^+ = n$, so that the conjunction of the induction assumption (4.30) and the preceding disjunction is true, that is,

$$n \notin n \wedge (n^+ \in n \vee n^+ = n).$$

This conjunction in turn implies

$$(n \notin n \wedge n^+ \in n) \vee (n \notin n \wedge n^+ = n), \tag{4.32}$$

with the Distributive Law for sentences (1.44). Next, we use this true disjunction to prove the sentence $n \in n$ by cases. In case $n \notin n \wedge n^+ \in n$ is true, we have that the second part $n^+ \in n$ of that conjunction is true in particular, which we may also write as $n^+ \in_{\mathbb{N}} n$ in view of (4.19). Let us now recall that $n \in n^+$ also holds because of (2.305), which we may equivalently write as $n \in_{\mathbb{N}} n^+$. Thus, the conjunction of $n \in_{\mathbb{N}} n^+$ and $n^+ \in_{\mathbb{N}} n$ is true, which then implies $n \in_{\mathbb{N}} n$ with the transitivity (4.20) of $\in_{\mathbb{N}}$, and consequently also the equivalent $n \in n$, as desired. If the second part $n \notin n \wedge n^+ = n$ of the disjunction (4.32) is true, then $n^+ = n$ holds in particular. We may therefore apply substitution to the previously established fact $n \in n^+$ to obtain $n \in n$ again, completing the proof by cases. As this result clearly contradicts the induction assumption (4.30), the proof of the implication (4.29) is complete. Then, as n is arbitrary, we further conclude that the induction step holds, which completes the proof of (4.21) via mathematical induction. □

Recalling the definition of an irreflexive partial ordering, we may immediately restate the parts b) and c) of the preceding lemma as the following sentence.

Corollary 4.5. *The binary relation of belonging $\in_{\mathbb{N}}$ is an irreflexive partial ordering of $\mathbb{N}$.*

Theorem 4.6 (Counting domain of natural numbers). *The following sentences are true.*

a) The function

$$s^+ : \mathbb{N} \to \mathbb{N}, \quad n \mapsto s^+(n) = n^+ \quad (= n \cup \{n\}) \tag{4.33}$$

exists uniquely.

b) Furthermore, the ordered triple $(\mathbb{N}, s^+, 0)$ constitutes a counting domain.

Proof. Concerning a), let us first recall that $\mathbb{N}$ is an inductive set according to Theorem 2.104d), so that $\emptyset \in \mathbb{N}$ holds and $n^+ = n \cup \{n\}$ is a uniquely specified set in $\mathbb{N}$ for any $n \in \mathbb{N}$. Consequently, in view of Theorem 3.160, there exists the unique function s^+ with domain $\mathbb{N}$ such that $s^+(n) = n^+$ holds for any $n \in \mathbb{N}$. To prove that $\mathbb{N}$ is a codomain of s^+, we verify $\mathrm{ran}(s^+) \subseteq \mathbb{N}$. For this purpose, we apply the definition of a subset and prove the equivalent

$$\forall m\, (m \in \mathrm{ran}(s^+) \Rightarrow m \in \mathbb{N}). \tag{4.34}$$

We let m be an arbitrary element of $\mathrm{ran}(s^+)$, so that, by definition of a range, there exists an element, say $\bar{n}$, such that $(\bar{n}, m) \in s^+$ is true. Since s^+ is a function, we may write this also as $m = s^+(\bar{n})$. By definition of s^+, we obtain $(m =)\ s^+(\bar{n}) = \bar{n}^+$, so that $m = \bar{n}^+$. Then, $(m =)\ \bar{n}^+ = \bar{n} \cup \{\bar{n}\}$ is, by definition of $\mathbb{N}$, an element of $\mathbb{N}$, which gives the desired $m \in \mathbb{N}$. Since

m was arbitrary, it follows that (4.34) is true, which means that the range of s^+ is a subset of $\mathbb{N}$. By definition of a codomain, we therefore have that s^+ is a function with codomain $\mathbb{N}$.

Concerning b), we first verify that $(\mathbb{N}, s^+, 0)$ satisfies (4.1), i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \neq 0). \tag{4.35}$$

For this purpose, we let n be arbitrary in $\mathbb{N}$. Since $n \in \{n\}$ holds according to (2.153), it evidently follows with (2.210) that $n \in n \cup \{n\}$ $[= n^+]$ holds, which shows that there exists an element in n^+. Thus, n^+ is clearly not the empty set $\emptyset$ $[= 0]$, so that $n^+ \neq 0$ is true. This proves the implication in (4.35), and since n is arbitrary, we may therefore conclude that (4.35) holds, which means that Property 1 of a counting domain is satisfied by $\mathbb{N}$, s^+ and 0.

Regarding Property 2, we prove

$$\forall m, n\,([m, n \in \mathbb{N} \wedge m^+ = n^+] \Rightarrow m = n). \tag{4.36}$$

For this purpose, we carry out a proof of a universal sentence and a proof by contradiction. Letting m and n be arbitrary, we assume the multiple conjunction

$$m, n \in \mathbb{N} \wedge m^+ = n^+ \wedge m \neq n \tag{4.37}$$

and show that this implies a contradiction. This conjunction implies in particular $m^+ = n^+$. With the fact that that $m \in m^+$ holds in view of (2.305), this yields $m \in n^+$. The latter means $m \in n \cup \{n\}$ (by definition of a successor) and therefore $m \in n \vee m \in \{n\}$ (by definition of the union of a pair), and equivalently $m \in n \vee m = n$ with (2.169). Since (4.37) implies in particular $m \neq n$, so that the second part $m = n$ of the preceding true disjunction is false, we may infer from this that the first part $m \in n$ of that disjunction is true. Similarly, the previously obtained equation $m^+ = n^+$ implies with the previously established fact $n \in n^+$ that $n \in m^+$ $(= m \cup \{m^+\})$ holds (using also the definition of a successor), and therefore $n \in m \vee n \in \{m\}$ (applying the definition of the union of a pair). Here, we may substitute $n \in \{m\}$ by the equivalent $n = m$ (using (2.169)) to obtain the disjunction $n \in m \vee n = m$. Recalling that $m = n$ is false, we see that the first part $n \in m$ of this true disjunction holds. We thus showed that $n \in m$ and $m \in n$ are both true, for which we may write equivalently $n \in_{\mathbb{N}} m$ and $m \in_{\mathbb{N}} n$ due to (4.19). Consequently, the transitivity (4.20) of $\in_{\mathbb{N}}$ yields $n \in_{\mathbb{N}} n$, in contradiction to the fact that $\neg n \in_{\mathbb{N}} n$ holds because of the irreflexivity (4.21) of $\in_{\mathbb{N}}$. Thus, the proof of the implication in (4.36) is complete, and since m and n are arbitrary, we may therefore conclude that

(4.36) holds, so that Property 2 of a counting domain is also satisfied.

Property 3 reads

$$\forall M\,([M \subseteq \mathbb{N} \,\wedge\, 0 \in M \,\wedge\, \forall n\,(n \in M \Rightarrow n^+ \in M)] \Rightarrow M = \mathbb{N}), \qquad (4.38)$$

which we recognize to be the Principle of Mathematical Induction (applying the definition of an inductive set). Thus, the proof of b) is complete. □

We may apply Theorem 4.1 immediately to the counting domain $(\mathbb{N}, s^+, 0)$ in order to characterize the natural numbers accordingly.

Corollary 4.7. *A natural number is* 0 *or the successor of another natural number, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow [n = 0 \,\vee\, \exists m\,(m \in \mathbb{N} \,\wedge\, m \neq n \,\wedge\, m^+ = n)]). \qquad (4.39)$$

The following two results immediately follow by applying the Propositions 4.2 and 4.3 to the counting domain of natural numbers.

Corollary 4.8. *The successor function of the counting domain* $(\mathbb{N}, s^+, 0)$ *is a bijection from* $\mathbb{N}$ *to* $\mathbb{N}_+$*, that is,*

$$s^+ : \mathbb{N} \rightleftarrows \mathbb{N}_+. \qquad (4.40)$$

Proof. Since $\mathbb{N}_+ = \mathbb{N} \setminus \{0\}$ holds by definition of the set of positive natural numbers, (4.40) follows directly from (4.12). □

Corollary 4.9. *Any natural number is different from its successor, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \neq n). \qquad (4.41)$$

Exercise 4.1. Verify that the successor of any natural number is element of the set of positive natural numbers, that is,

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \in \mathbb{N}_+). \qquad (4.42)$$

(Hint: Use (4.35), (2.169), (4.33), and (2.307).)

Note 4.1. Since (4.35) is equivalent to

$$\neg\exists n\,(n \in \mathbb{N} \,\wedge\, n^+ = 0) \qquad (4.43)$$

due to the Negation Law for existential conjunctions, this means that 0 has no predecessor.

Note 4.2. As every natural number is a subset of $\mathbb{N}$ according to Proposition 2.110), we see that every natural number is an element of the power set of $\mathbb{N}$, so that $\mathcal{P}(\mathbb{N})$ may be taken as the codomain of the successor function s^+ on $\mathbb{N}$, i.e. we may write instead of (4.33)

$$s^+ : \mathbb{N} \to \mathcal{P}(\mathbb{N}), \quad n \mapsto s^+(n) = n^+ \quad (= n \cup \{n\}). \qquad (4.44)$$

4.1.2. Mathematical induction and recursion in counting domains

Note 4.3. In view of the similarity of Property 3 of a counting domain $(C, s, 0_C)$ and the Principle of Mathematical Induction for $(\mathbb{N}, s^+, 0)$, the former may be viewed as a generalization of the latter. Bearing in mind that the former is a defining property whereas the latter is a proven fact, we will nevertheless speak also of the Principle of Mathematical Induction in the context of an arbitrary counting domain. Similarly, we will call a set M which satisfies

$$0_C \in M \wedge \forall n \, (n \in M \Rightarrow s(n) \in M) \tag{4.45}$$

an *inductive set* with respect to $(C, s, 0_C)$, indicating the analogy to the definite property (2.289) of an inductive set. It will then also be convenient to call 0_C the *initial element* of M or of C and $s(n)$ the *successor* of n (in C).

Since Proposition 2.107 and the related Method 2.2 (i.e., proof by mathematical induction) essentially involves the elements of the specific counting domain $(\mathbb{N}, s^+, 0)$, their generalization is straightforward.

Exercise 4.2. Establish for any counting domain $(C, s, 0_C)$ and for an arbitrary formula $\varphi(n)$ the truth of the following sentences.

a) There exists a unique set

$$X = \{n : n \in C \wedge \varphi(n)\} \tag{4.46}$$

which contains precisely all the elements n in C for which $\varphi(n)$ is true, and this set X is a subset of C.

b) If this set X is inductive, then $\varphi(n)$ is true for all $n \in C$, that is,

$$[0_C \in X \wedge \forall n \, (n \in X \Rightarrow s(n) \in X)] \Rightarrow \forall n \, (n \in \mathbb{N} \Rightarrow \varphi(n)). \tag{4.47}$$

c) If

$$\varphi(0_C) \tag{4.48}$$

and

$$\forall n \, (n \in C \Rightarrow [\varphi(n) \Rightarrow \varphi(s(n))]) \tag{4.49}$$

are true, then the set X specified in a) satisfies (4.45), i.e. X is an inductive set.

(Hint: Proceed as in the proof of Proposition 2.107.)

Method 4.1 (Proof by mathematical induction for counting domains). To prove for an arbitrary counting domain $(C, s, 0_C)$ that a given formula $\varphi(n)$ holds for all elements of C, we show that the so-called *base case* (4.48) and *induction step* (4.49) are true, where $\varphi(n)$ is called the *induction assumption*.

Exercise 4.3. Prove Theorem 4.1 alternatively by applying a proof by mathematical induction.

Next, we introduce a method for defining a new function whose values are determined successively in the following *recursive* sense. Except for the initial value, which is specified to be a given element of the underlying set, we determine each value of the new function by evaluating a given function at two arguments, where the first argument is obtained by counting the steps taken to determine the preceding value, which value itself constitutes the second argument. The following theorem establishes the uniqueness of a function defined by this method (which we then state formally afterwards).

Theorem 4.10 (Recursion Theorem). *The following sentences are true for any counting domain $(C, s, 0_C)$, any set A, any function $f : C \times A \to A$, and any $a \in A$.*

a) Letting $\varphi(X)$ be the definite property

$$(0_C, a) \in X \wedge \forall n, b\,((n, b) \in X \Rightarrow (s(n), f(n, b)) \in X), \tag{4.50}$$

there exists a unique set

$$\mathcal{X} = \{X : X \subseteq C \times A \wedge \varphi(X)\} \tag{4.51}$$

consisting of all the subsets of $C \times A$ which satisfy $\varphi(X)$. Then, the intersection

$$u = \bigcap \mathcal{X} \tag{4.52}$$

satisfies $\varphi(u)$.

b) Furthermore, u satisfies the universal sentence

$$\forall b\,(b \in A \Rightarrow [(0_C, b) \in u \Rightarrow b = a]). \tag{4.53}$$

c) Moreover, u satisfies the universal sentence

$$\begin{aligned} &\forall n, b'\,([\exists! b\,(b \in A \wedge (n, b) \in u) \wedge (s(n), b') \in u] \\ &\quad \Rightarrow \forall b\,([b \in A \wedge (n, b) \in u] \Rightarrow b' = f(n, b)). \end{aligned} \tag{4.54}$$

d) Finally, there exists a unique function $u : C \to A$ such that

$$u(0_C) = a \wedge \forall n\,(n \in C \Rightarrow u(s(n)) = f(n, u(n))). \tag{4.55}$$

Proof. We let C, s, 0_C, A, f and a be arbitrary. Here, we assume that $(C, s, 0_C)$ is a counting domain, that f is a function from $\mathbb{N} \times A$ to A, and moreover that a is an element of A.

Concerning a), we notice that the subsets of $C \times A$ are elements of the power set $\mathcal{P}(C \times A)$, so that we may apply the Axiom of Specification and the Equality Criterion for sets to obtain the true sentence

$$\exists! \mathcal{X}\, \forall X\, (X \in \mathcal{X} \Leftrightarrow [X \in \mathcal{P}(C \times A) \wedge \varphi(X)]).$$

Thus, the set $\mathcal{X}$ satisfies

$$\forall X\, (X \in \mathcal{X} \Leftrightarrow [X \in \mathcal{P}(C \times A) \wedge \varphi(X)]), \tag{4.56}$$

and the intersection $u = \bigcap \mathcal{X}$ is uniquely specified, where

$$\forall y\, (y \in u \Leftrightarrow \forall X\, (X \in \mathcal{X} \Rightarrow y \in X)) \tag{4.57}$$

holds by definition of the intersection of a set system. We now prove that $\varphi(u)$ is true, i.e. we prove the conjunction

$$(0_C, a) \in u \wedge \forall n, b\, ((n, b) \in u \Rightarrow (s(n), f(n, b)) \in u). \tag{4.58}$$

Regarding the first part of this conjunction, we show that

$$\forall X\, (X \in \mathcal{X} \Rightarrow (0_C, a) \in X) \tag{4.59}$$

is true, which will imply the desired $(0_C, a) \in u$ with (4.57). Letting X be arbitrary, we assume $X \in \mathcal{X}$, which implies with (4.56) the conjunction of $X \in \mathcal{P}(C \times A)$ and $\varphi(X)$, and therefore in particular $\varphi(X)$. Thus, X satisfies the conjunction (4.50), so that $(0_C, a) \in X$ holds in particular. Since X is arbitrary, we therefore conclude that the universal sentence (4.59) is true, which implies $(0_C, a) \in u$ in view of (4.57). To prove the second part of the conjunction (4.58), we let n and b be arbitrary and assume $(n, b) \in u$, which implies

$$\forall X\, (X \in \mathcal{X} \Rightarrow (n, b) \in X) \tag{4.60}$$

with (4.57). We now verify the truth of

$$\forall X\, (X \in \mathcal{X} \Rightarrow (s(n), f(n, b)) \in X). \tag{4.61}$$

To do this, we let X be arbitrary in $\mathcal{X}$, which implies $(n, b) \in X$ with (4.60). Furthermore, $X \in \mathcal{X}$ implies in particular $\varphi(X)$ because of (4.56) and therefore in particular

$$\forall n, b\,((n, b) \in X \Rightarrow (s(n), f(n, b)) \in X).$$

Due to $(n, b) \in X$ it follows from this universal sentence that $(s(n), f(n, b)) \in X$. As X is arbitrary, we therefore conclude that (4.61) is indeed true. The latter further implies $(s(n), f(n, b)) \in u$ with (4.57). As n and b were arbitrary, we then conclude that the second part of the conjunction, and thus the entire conjunction (4.58) holds, which means that $\varphi(u)$ is true.

Concerning b), we let b be arbitrary, assume $b \in A$, and prove then the implication

$$(0_C, b) \in u \Rightarrow b = a$$

by contradiction. To do this, we assume $(0_C, b) \in u$ and $b \neq a$, and we first verify $\varphi(u \setminus \{(0_C, b)\})$, i.e. that $u \setminus \{(0_C, b)\}$ satisfies the conjunction (4.50). Concerning the first part of the conjunction, let us observe that the equivalence

$$(0_C, a) = (0_C, b) \;\Leftrightarrow\; (0_C = 0_C \,\wedge\, a = b)$$

is true due to (3.3); here, $a = b$ is false by assumption, so that the conjunction is also false. Then, the left-hand side $(0_C, a) = (0_C, b)$ of the equivalence is also false. This implies with (2.169) that $(0_C, a) \in \{(0_C, b)\}$ false as well, which means that $(0_C, a) \notin \{(0_C, b)\}$ is true. Now, recalling from a) that $\varphi(u)$ is true, so that $(0_C, a) \in u$ holds in particular, we obtain the conjunction

$$(0_C, a) \in u \,\wedge\, (0_C, a) \notin \{(0_C, b)\},$$

which is equivalent to $(0_C, a) \in u \setminus \{(0_C, b)\}$, by definition of the set difference. Thus, $u \setminus \{(0_C, b)\}$ satisfies the first part of the conjunction (4.50). Concerning the second part, we let n and $\bar{b}$ be arbitrary and assume $(n, \bar{b}) \in u \setminus \{(0_C, b)\}$. Since $u \setminus \{(0_C, b)\} \subseteq u$ holds due to (2.125), we have that $(n, \bar{b}) \in u \setminus \{(0_C, b)\}$ implies $(n, \bar{b}) \in u$ with the definition of a subset. As $\varphi(u)$ is true, so that u satisfies in particular the second part of the conjunction (4.50), it follows from $(n, \bar{b}) \in u$ that $(s(n), f(n, \bar{b})) \in u$. Let us now notice the truth of the equivalence

$$(s(n), f(n, \bar{b})) = (0_C, b) \;\Leftrightarrow\; (s(n) = 0_C \,\wedge\, f(n, \bar{b}) = b)$$

in light of (3.3). Here, $s(n) = 0_C$ is false because of Property 1 of a counting domain, so that the conjunction is false as well. Thus, the left-hand side $(s(n), f(n, \bar{b})) = (0_C, b)$ of the equivalence is also false. Consequently,

$(s(n), f(n, \bar{b})) \notin \{(0_C, b)\}$ (applying again (2.169). We therefore obtain with the previously established $(s(n), f(n, \bar{b})) \in u$ the conjunction

$$(s(n), f(n, \bar{b})) \in u \wedge (s(n), f(n, \bar{b})) \notin \{(0_C, b)\},$$

which means $(s(n), f(n, \bar{b})) \in u \setminus \{(0_C, b)\}$ (by definition of the set difference). As n and $\bar{b}$ were arbitrary, we therefore conclude that $u \setminus \{(0_C, b)\}$ satisfies the second part of the conjunction (4.50), which completes the proof of $\varphi(u \setminus \{(0_C, b)\})$. Next, we verify that

$$u \setminus \{(0_C, b)\} \subseteq u \subseteq X \subseteq C \times A.$$

holds for any $X \in \mathcal{X}$. We already established the first of these inclusions before. Letting X be arbitrary in $\mathcal{X}$, the second inclusion $u \subseteq X$ holds with (4.52) and Proposition 2.29. The third inclusion holds with the definition (4.51) of $\mathcal{X}$. Since $\subseteq$ is a partial ordering (see Theorem 3.64) and therefore transitive, we obtain $u \setminus \{(0_C, b)\} \subseteq C \times A$ (which then holds for any $X \in \mathcal{X}$). The conjunction of this and $\varphi(u \setminus \{(0_C, b)\})$ now implies with (4.51) that $u \setminus \{(0_C, b)\}$ is an element of $\mathcal{X}$. As noted before, $u \subseteq X$ holds for any $X \in \mathcal{X}$, so that $u \subseteq u \setminus \{(0_C, b)\}$ holds in particular. Consequently, $(0_C, b) \in u$ (which we assumed initially) implies $(0_C, b) \in u \setminus \{(0_C, b)\}$, which means

$$(0_C, b) \in u \wedge (0_C, b) \notin \{(0_C, b)\}.$$

Here, $(0_C, b) \notin \{(0_C, b)\}$ contradicts the evident fact that $(0_C, b) \in \{(0_C, b)\}$ is true, so that the preceding implication constitutes a contradiction, which completes the proof of the implication $(0_C, b) \in u \Rightarrow b = a$. As b was arbitrary, we therefore conclude that b) holds, as claimed.

Concerning c), we let n and b' be arbitrary, assume that there exists a unique $b \in A$ with $(n, b) \in u$ and that $(s(n), b') \in u$ holds, and let then b be arbitrary. We now prove the implication by contradiction, assuming that $b \in A$, $(n, b) \in u$ and $b' \neq f(n, b)$ are true. Due to the assumed existential sentence, the arbitrarily selected b is in fact unique. Next, we verify that $\varphi(u \setminus \{(s(n), b')\})$ holds, i.e. that $u \setminus \{(s(n), b')\}$ satisfies (4.50). Regarding the first part of the conjunction, we notice the truth of the equivalence

$$(0_C, a) = (s(n), b') \Leftrightarrow (0_C = s(n) \wedge a = b') \tag{4.62}$$

in view of (3.3), where $0_C = s(n)$ is false by Property 1 of a counting domain. Therefore, the conjunction in (4.62) and thus also the left-hand side $(0_C, a) = (s(n), b')$ of the equivalence is false, which implies with (2.169) that $(0_C, a) \in \{(s(n), b')\}$ is false as well; thus, $(0_C, a) \notin \{(s(n), b')\}$ is true. Because u satisfies $\varphi(u)$ (as shown in a)) and therefore in particular $(0_C, a) \in u$, we obtain the conjunction

$$(0_C, a) \in u \wedge (0_C, a) \notin \{(s(n), b')\},$$

which means $(0_C, a) \in u \setminus \{(s(n), b')\}$ (by definition of the set difference). To show that $u \setminus \{(s(n), b')\}$ satisfies also the second part of the conjunction (4.50), we let $\bar{n}$ and $\bar{b}$ be arbitrary, assume $(\bar{n}, \bar{b}) \in u \setminus \{(s(n), b')\}$, and show that this implies

$$(s(\bar{n}), f(\bar{n}, \bar{b})) \in u \setminus \{(s(n), b')\},$$

or equivalently

$$(s(\bar{n}), f(\bar{n}, \bar{b})) \in u \wedge (s(\bar{n}), f(\bar{n}, \bar{y})) \notin \{(s(n), b')\}. \tag{4.63}$$

Due to $u \setminus \{(s(n), b')\} \subseteq u$ (again with (2.125)), we have that $(\bar{n}, \bar{b}) \in u \setminus \{(s(n), b')\}$ implies $(\bar{n}, \bar{b}) \in u$ (by definition of a subset). Since $\varphi(u)$ is true, u satisfies in particular the second part of the conjunction (4.50); with this, $(\bar{n}, \bar{b}) \in u$ implies $(s(\bar{n}), f(\bar{n}, \bar{b})) \in u$, so that the first part of the conjunction (4.63) holds. To prove the second part, which is equivalent to

$$(s(\bar{n}), f(\bar{n}, \bar{b})) \neq (s(n), b') \tag{4.64}$$

because of (2.169), let us observe the truth of the equivalence (using again (3.3))

$$(s(\bar{n}), f(\bar{n}, \bar{b})) = (s(n), b') \Leftrightarrow (s(\bar{n}) = s(n) \wedge f(\bar{n}, \bar{b}) = b'). \tag{4.65}$$

We now consider the two exhaustive cases $\bar{n} \neq n$ and $\bar{n} = n$. Regarding the first case, we notice that the implication $s(\bar{n}) = s(n) \Rightarrow \bar{n} = n$ is true by Property 2 of a counting domain. By definition of an implication, the case assumption that $\bar{n} = n$ is false then implies that $s(\bar{n}) = s(n)$ is also false. Consequently, the conjunction in (4.65) is also false, and therefore the left-hand side of the equivalence is false as well, which means that (4.64) is true. Regarding the second case $\bar{n} = n$, we see that the previously established $(\bar{n}, \bar{b}) \in u$ is then equivalent to $(n, \bar{b}) \in u$. Since b was initially assumed to be the unique element satisfying $(n, b) \in u$, we obtain $\bar{b} = b$. Therefore, $f(\bar{n}, \bar{b}) = b'$ is equivalent to $f(n, b) = b'$, which false by our initial assumption. Consequently, the conjunction in (4.65) and thus the left-hand side of the equivalence is false also in the second case, so that (4.64) is true in any case. This completes the proof of the conjunction (4.63), and as $\bar{n}$ and $\bar{b}$ are arbitrary, it follows that $u \setminus \{(s(n), b')\}$ satisfies (4.50), i.e. $\varphi(u \setminus \{(s(n), b')\})$. We already demonstrated the truth of the inclusions

$$u \setminus \{(s(n), b')\} \subseteq u \subseteq X \subseteq C \times A.$$

for any $X \in \mathcal{X}$ (see also the proof of b)), so that $u \setminus \{(s(n), b')\}$ is a subset of $C \times A$ (using again the transitivity of $\subseteq$). The conjunction of this and the previously established true sentence $\varphi(u \setminus \{(s(n), b')\})$ now implies $u \setminus \{(s(n), b')\} \in \mathcal{X}$ with (4.51). We already noted before that $u \subseteq X$ holds for any $X \in \mathcal{X}$, so that in particular $u \subseteq u \setminus \{(s(n), b')\}$. Then, the initial assumption $(s(n), b') \in u$ implies $(s(n), b') \in u \setminus \{(s(n), b')\}$, which means

$$(s(n), b') \in u \wedge (s(n), b') \notin \{(s(n), b')\}.$$

Here, $(s(n), b') \notin \{(s(n), b')\}$ contradicts the fact that $(s(n), b')$ is an element of $\{(s(n), b')\}$, so that the preceding conjunction is a contradiction. Thus, the proof of the implication in (4.54) is complete; as n and b were arbitrary, we therefore conclude that c) is true.

Concerning d), we begin with the existential part and show that the binary relation u, specified by (4.52) based on (4.51), is a function from C to A satisfying (4.55). We first prove by means of the Function Criterion that $u : C \to A$, i.e. we prove

$$\forall n \, (n \in C \Rightarrow \exists! b \, (b \in A \wedge (n, b) \in u)). \tag{4.66}$$

For this purpose, we apply a proof by mathematical induction. Concerning the base case ($n = 0_C$), we observe that the uniquely existential sentence in (4.66) with $n = 0_C$ is, in view of the Criterion for unique existence, equivalent to

$$\begin{aligned} &\exists b \, (b \in A \wedge (0_C, b) \in u) \\ &\quad \wedge \forall b, b' \, ([b \in A \wedge (0_C, b) \in u \wedge b' \in A \wedge (0_C, b') \in u] \Rightarrow b = b'). \end{aligned} \tag{4.67}$$

We already demonstrated in a) that $(0_C, a) \in u$ is true (where $a \in A$), so that existential part in (4.67) holds. Regarding the uniqueness part, we let b and b' be arbitrary and assume $b \in A$, $(0_C, b) \in u$, $b' \in A$, and $(0_C, b')$. These assumptions evidently imply $b = a$ and $b' = a$ with (4.53), which equations give the desired $b = b'$ after substitution. As b and b' are arbitrary, we therefore conclude that the second part of the conjunction (4.67) also holds, which completes the proof of the uniquely existential sentence in (4.66) for $n = 0_C$. Regarding the induction step, we let n be arbitrary in C, make the induction assumption

$$\exists! b \, (b \in A \wedge (n, b) \in u), \tag{4.68}$$

and prove

$$\exists! b \, (b \in A \wedge (s(n), b) \in u),$$

which is equivalent to

$$\begin{aligned}&\exists b\,(b \in A \,\wedge\, (s(n), b) \in u) &(4.69)\\&\quad\wedge\, \forall b', b''\,([b' \in A \,\wedge\, (s(n), b') \in u \,\wedge\, b'' \in A \,\wedge\, (s(n), b'') \in u] \Rightarrow b' = b'').\end{aligned}$$

We let b be the unique element in A satisfying $(n, b) \in u$ according to the induction assumption. This implies $(s(n), f(n, b)) \in u$ since u satisfies (4.50), where $f(n, b) \in A$ holds by definition of f. Thus, the existential part in (4.69) is true. Regarding the uniqueness part, we let b' and b'' be arbitrary and assume $b' \in A$, $(s(n), b') \in u$, $b'' \in A$, and $(s(n), b'') \in u$. Then, the conjunction of the induction assumption (4.68) and $(s(n), b') \in u$ implies the universal sentence

$$\forall b\,([b \in A \,\wedge\, (n, b) \in u] \Rightarrow b' = f(n, b)),$$

so that the conjunction of $b \in A$ and $(n, b) \in u$ further implies $b' = f(n, b)$. Similarly, the conjunction of (4.68) and $(s(n), b'') \in u$ implies

$$\forall b\,([b \in A \,\wedge\, (n, b) \in u] \Rightarrow b'' = f(n, b)),$$

so that the conjunction of $b \in A$ and $(n, b) \in u$ now gives $b'' = f(n, b)$ $(= b')$. Thus, $b' = b''$ holds, and since b' and b'' are arbitrary, it follows that the second part of the conjunction (4.69) is true. As n was arbitrary, we therefore conclude that the induction step holds, so that the proof of (4.66) is complete. We thus proved that u is a function with domain C and codomain A. We may then apply Notation 3.4 to write the previously established fact $(0_C, a) \in u$ as $u(0_C) = a$, which shows that u satisfies the first part of the conjunction (4.55). With respect to the second part, we let n be arbitrary in C. Because of the Function Criterion, $u : C \to A$ then implies that there exists the unique b in A with $(n, b) \in u$, that is, with $u(n) = b$. As u satisfies (4.50), $(n, b) \in u$ implies $(s(n), f(n, b)) \in u$, that is, $(s(n), f(n, u(n))) \in u$, that is, $u(s(n)) = f(n, u(n))$. Since n is arbitrary, we conclude that u satisfies also the second part of the conjunction (4.55).

It remains for us to prove the uniqueness part of the sentence d). For this purpose, we verify

$$\begin{aligned}&\forall u, u'\,([u : C \to A \,\wedge\, u(0_C) = a \,\wedge\, \forall n\,(n \in C \Rightarrow u(s(n)) = f(n, u(n)))\\&\qquad\wedge\, u' : C \to A \,\wedge\, u'(0_C) = a \,\wedge\, \forall n\,(n \in C \Rightarrow u'(s(n)) = f(n, u'(n)))]\\&\quad\Rightarrow u = u').\end{aligned}$$

Letting u and u' be arbitrary functions from C to A such that the conjunctions

$$u(0_C) = a \wedge \forall n\,(n \in C \Rightarrow u(s(n)) = f(n, u(n))) \tag{4.70}$$

$$u'(0_C) = a \wedge \forall n\,(n \in C \Rightarrow u'(s(n)) = f(n, u'(n))) \tag{4.71}$$

hold, we now prove $u = u'$ by applying Method 3.2. To do this, we demonstrate that $u(n) = u'(n)$ holds for all $n \in C$. For this purpose, we apply a proof by mathematical induction. Concerning the base case ($n = 0_C$), we have $u(0_C) = a = u'(0_C)$ due to (4.70) – (4.71) and therefore $u(0_C) = u'(0_C)$. Concerning the induction step, we let n be arbitrary in C, make the induction assumption $u(n) = u'(n)$, and show that this implies $u(s(n)) = u'(s(n))$. Let us observe that $n \in C$ implies with (4.70) on the one hand $u(s(n)) = f(n, u(n))$, which is equivalent to

$$u(s(n)) = f(n, u'(n)) \tag{4.72}$$

because of the induction assumption $u(n) = u'(n)$. On the other hand, $n \in C$ implies $u'(s(n)) = f(n, u'(n))$ with (4.71), so that (4.72) is equivalent to the desired $u(s(n)) = u'(s(n))$. As n is arbitrary, we therefore conclude that the induction step holds, which completes the proof by mathematical induction of $u = u'$. Since u and u' were also arbitrary, we further conclude that the uniqueness part of the sentence d) is true as well. This completes the proof of d).

As C, s, 0_C, A, f and a were initially arbitrary, we may finally conclude that the theorem holds, as claimed. □

Method 4.2 (Definition by recursion). To define for an arbitrary counting domain $(C, s, 0_C)$, an arbitrary set A, an arbitrary function $f : C \times A \to A$ and an arbitrary $a \in A$ the function $u : C \to A$ which satisfies (4.55), we will write

$$(1) \quad u(0_C) = a, \tag{4.73}$$

$$(2) \quad u(s(n)) = f(n, u(n)) \quad \text{for any } n \in C. \tag{4.74}$$

In case of the counting domain $(\mathbb{N}, s^+, 0)$, we will define by recursion as follows.

Method 4.3 (Definition by recursion (for $\mathbb{N}$)). To define for an arbitrary set A, an arbitrary function $f : \mathbb{N} \times A \to A$ and an arbitrary $a \in A$ the function $u : \mathbb{N} \to A$ which satisfies (4.55) with respect to the particular counting domain $(\mathbb{N}, s^+, 0)$, we will write

$$(1) \quad u_0 = a, \tag{4.75}$$

$$(2) \quad u_{n^+} = f(n, u_n) \quad \text{for any } n \in \mathbb{N}. \tag{4.76}$$

4.2. Initial Segments of Counting Sets

We now intend to apply the preceding method in order to recursively define a function u whose values are certain subsets of a counting set C. We prepare this definition by specifying a function f (as required by the Recursion Theorem and the Definition by recursion), which determines how these subsets are to be formed.

Proposition 4.11. *For any counting domain* $(C, s, 0_C)$ *there exists a unique set*

$$f = \{((n, B), B \cup \{s(n)\}) : n \in C \wedge B \subseteq C\}$$

consisting of all the ordered triples (n, B, V) *with* $n \in C$ *and* $B \subseteq C$ *such that* V *is the union of* B *and the singleton* $\{s(n)\}$, *and this set* f *is a function from* $C \times \mathcal{P}(C)$ *to* $\mathcal{P}(C)$, *i.e.*

$$f : C \times \mathcal{P}(C) \to \mathcal{P}(C), \quad (n, B) \mapsto B \cup \{s(n)\}. \tag{4.77}$$

Proof. We let $(C, s, 0_C)$ be an arbitrary counting domain. We may then apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true uniquely existential sentence

$$\exists! f \, \forall z \, (z \in f \Leftrightarrow [z \in C \times \mathcal{P}(C) \times \mathcal{P}(C)$$
$$\wedge \, \exists n, B, V \, (V = B \cup \{s(n)\} \wedge (n, B, V) = z)]).$$

Thus, the set f satisfies

$$\forall z \, (z \in f \Leftrightarrow [z \in C \times \mathcal{P}(C) \times \mathcal{P}(C)$$
$$\wedge \, \exists n, B, V \, (V = B \cup \{s(n)\} \wedge ((n, B), V) = z)]). \tag{4.78}$$

We first observe that f is a subset of $(C \times \mathcal{P}(C)) \times \mathcal{P}(C)$, because $z \in f$ evidently implies in particular $z \in (C \times \mathcal{P}(C)) \times \mathcal{P}(C)$ for any z. We may then view f as a binary relation included in $X \times \mathcal{P}(C)$, where $X = C \times \mathcal{P}(C)$. Therefore, we may apply the Function Criterion to prove that $f : X \to \mathcal{P}(C)$. For this purpose, we demonstrate the truth of

$$\forall x \, (x \in C \times \mathcal{P}(C) \Rightarrow \exists! y \, (y \in \mathcal{P}(C) \wedge (x, y) \in f)). \tag{4.79}$$

We let x be arbitrary in $C \times \mathcal{P}(C)$, so that (by definition of a Cartesian product) there exists an element of C, say $\bar{n}$, and an element of $\mathcal{P}(C)$, say $\bar{B}$, such that $(\bar{n}, \bar{B}) = x$. We now show that this implies the uniquely existential sentence in (4.79), which is equivalent to

$$\exists y \, (y \in \mathcal{P}(C) \wedge (x, y) \in f)) \tag{4.80}$$
$$\wedge \, \forall y, y' \, (y \in \mathcal{P}(C) \wedge (x, y) \in f \wedge y' \in \mathcal{P}(C) \wedge (x, y') \in f)$$

because of the Criterion for unique existence. Regarding the existential part, we recall thet s is a function from C to C (by definition of a counting domain), so that the function value $s(\bar{n})$ exists in C. It then follows that the singleton $\{s(\bar{n})\}$ is a subset of $\mathcal{P}(C)$ (see Exercise 2.22); as $\bar{B} \in \mathcal{P}(C)$ implies $\bar{B} \subseteq C$ by definition of a power set, we have that the conjunction of $\bar{B} \subseteq C$ and $\{s(\bar{n})\} \subseteq C$ implies $\bar{B} \cup \{s(\bar{n})\} \subseteq C$ due to (2.252); consequently,

$$\bar{B} \cup \{s(\bar{n})\} \in \mathcal{P}(C). \tag{4.81}$$

We then obtain

$$(\bar{n}, \bar{B}, \bar{B} \cup \{s(\bar{n})\}) \in C \times \mathcal{P}(C) \times \mathcal{P}(C),$$

and there exist n, B, V such that $V = B \cup \{s(n)\}$ and $(n, B, V) = (\bar{n}, \bar{B}, \bar{B} \cup \{s(\bar{n})\})$ are both true (namely $\bar{n}$, $\bar{B}$ and $\bar{B} \cup \{s(\bar{n})\}$). Therefore,

$$[(\bar{n}, \bar{B}, \bar{B} \cup \{s(\bar{n})\}) =] \quad (x, \bar{B} \cup \{s(\bar{n})\}) \in f \tag{4.82}$$

holds with (4.78). The conjunction of (4.81) and (4.82) evidently proves the existential part of (4.80). Regarding the uniqueness part, we let y and y' be arbitrary and assume the multiple conjunction

$$y \in \mathcal{P}(C) \,\wedge\, (x, y) \in f \,\wedge\, y' \in \mathcal{P}(C) \,\wedge\, (x, y') \in f.$$

This conjunction implies in particular $(x, y) \in f$ and $(x, y') \in f$. The former further implies with (4.78) in particular that there exist n, B, V, say $\bar{n}'$, $\bar{B}'$ and $\bar{V}'$, such that

$$\bar{V}' = \bar{B}' \cup \{s(\bar{n}')\} \,\wedge\, ((\bar{n}', \bar{B}'), \bar{V}') = (x, y) \quad [= ((\bar{n}, \bar{B}), y)]$$

holds. This gives $\bar{n}' = \bar{n}$, $\bar{B}' = \bar{B}$ and $\bar{V}' = y$, and therefore $y = \bar{B} \cup \{s(\bar{n})\}$. Similarly, $(x, y') \in f$ implies with (4.78) in particular that there exist n, B, V, say $\bar{n}''$, $\bar{B}''$ and $\bar{V}''$, such that

$$\bar{V}'' = \bar{B}'' \cup \{s(\bar{n}'')\} \,\wedge\, (\bar{n}'', \bar{B}'', \bar{V}'') = (x, y') \quad [= ((\bar{n}, \bar{B}), y')]$$

is true. This gives $\bar{n}'' = \bar{n}$, $\bar{B}'' = \bar{B}$ and $\bar{V}'' = y'$, and therefore $y' = \bar{B} \cup \{s(\bar{n})\}$ $(= y)$. Thus, $y = y'$ holds, and since y and y' are arbitrary, it follows that the second part of the conjunction (4.80) is true as well. This completes the proof of the uniquely existential sentence in (4.79). As x was arbitrary, we then conclude that (4.79) holds, which implies $f : C \times \mathcal{P}(C) \to \mathcal{P}(C)$ with the Function Criterion. Since $(C, s, 0_C)$ was an arbitrary counting domain, we finally conclude that the proposition holds, as claimed. □

Using the denotations $A = \mathcal{P}(C)$ and $a = \{0_C\}$ and using the function f defined in the preceding proposition, we may evidently apply the method of definition by recursion to obtain the following new function u_C.

Definition 4.2 (Initial segment of a counting set). For any counting domain $(C, s, 0_C)$ we define the function $u_C : C \to \mathcal{P}(C)$ recursively by

$$(1) \quad u_C(0_C) = \{0_C\}, \tag{4.83}$$

$$(2) \quad u_C(s(n)) = f(n, u_C(n)) = u_C(n) \cup \{s(n)\} \quad \text{for any } n \in C, \tag{4.84}$$

where f is the function in (4.77). For any $n \in C$ (including $n = 0_C$), we then write for $u_C(n)$ also

$$\{0_C, \ldots, n\}, \tag{4.85}$$

and we call this set the *initial segment of* C (up to n).

Note 4.4. In view of the notation (4.85), the recursion equation (4.84) means that the initial segment of C up to the successor of an $n \in C$ equals the union of the initial segment of C up to n and the singleton formed by that successor, that is,

$$\forall n \, (n \in C \Rightarrow \{0_C, \ldots, s(n)\} = \{0_C, \ldots, n\} \cup \{s(n)\}). \tag{4.86}$$

Notation 4.1. In the particular instance of the counting domain $(\mathbb{N}, s^+, 0)$, we obtain for the *initial segment of* $\mathbb{N}$ (up to n)

$$(1) \quad u_{\mathbb{N}}(0) = \{0\}, \tag{4.87}$$

$$(2) \quad u_{\mathbb{N}}(n^+) = u_{\mathbb{N}}(n) \cup \{n^+\} \quad \text{for any } n \in \mathbb{N}, \tag{4.88}$$

and we write for any $n \in \mathbb{N}$ (including $n = 0$) instead of $u_{\mathbb{N}}(n)$ also

$$\{0, \ldots, n\}.$$

Note 4.5. Equation (4.88) means that the initial segment of $\mathbb{N}$ up to the successor of a natural number n equals the union of the initial segment of $\mathbb{N}$ up to n and the singleton formed by that successor, that is,

$$\forall n \, (n \in \mathbb{N} \Rightarrow \{0, \ldots, n^+\} = \{0, \ldots, n\} \cup \{n^+\}). \tag{4.89}$$

Proposition 4.12. *In case of the counting domain* $(\mathbb{N}, s^+, 0)$*, the function* $u_{\mathbb{N}}$ *is identical with the successor function* s^+*, i.e.*

$$u_{\mathbb{N}} = s^+. \tag{4.90}$$

Proof. According to Definition 4.2, the function $u_{\mathbb{N}} : \mathbb{N} \to \mathcal{P}(\mathbb{N})$ satisfies (4.87) – (4.88). Due to Note 4.2, the successor function in $(\mathbb{N}, s^+, 0)$ may be viewed as the function $s^+ : \mathbb{N} \to \mathcal{P}(\mathbb{N})$. As $u_{\mathbb{N}}$ and s^+ share the same domain we may apply the Equality Criterion for functions to prove $u_{\mathbb{N}} = s^+$. For this purpose, we verify

$$\forall n \, (n \in \mathbb{N} \Rightarrow u_{\mathbb{N}}(n) = s^+(n)) \tag{4.91}$$

by mathematical induction. Concerning the base case ($n = 0$), we obtain the equations

$$s^+(0) = 0^+ = 0 \cup \{0\} = \emptyset \cup \{0\} = \{0\} = u_{\mathbb{N}}(0)$$

using (4.44), (2.290), (2.49), (2.216), and finally (4.87). Concerning the induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption $u_{\mathbb{N}}(n) = s^+(n)$, and show that this implies $u_{\mathbb{N}}(n^+) = s^+(n^+)$. We now obtain the equations

$$s^+(n^+) = (n^+)^+ = n^+ \cup \{n^+\} = s^+(n) \cup \{n^+\} = u_{\mathbb{N}}(n) \cup \{n^+\} = u_{\mathbb{N}}(n^+)$$

with (4.44), (2.290), again (4.44), then the induction assumption, and finally (4.84). As n is arbitrary, we therefore conclude that the induction step is true, which completes the proof by mathematical induction of (4.91), and thus the proof of $u_{\mathbb{N}} = s^+$. □

Notation 4.2. We therefore have three ways at our disposal to denote the initial segment of $\mathbb{N}$ up to a natural number n, viz.

$$u_{\mathbb{N}}(n) = n^+ = \{0, \ldots, n\}, \tag{4.92}$$

The dots within the notation $\{0_C, \ldots, n\}$ for an initial segment of C up to n suggest that such a set contains, besides 0_C and n, all of the elements that 'succeed' 0_C and 'precede' n. The task for the remainder of this section is to bring out more clearly what is meant by these notions.

Proposition 4.13. *For any counting domain $(C, s, 0_C)$ it is true that the initial segment of C up to an $n \in C$ contains n, i.e.*

$$\forall n \, (n \in C \Rightarrow n \in \{0_C, \ldots, n\}). \tag{4.93}$$

Proof. We let C, s and 0_C be arbitrary, assume $(C, s, 0_C)$ to be a counting domain, and prove the universal sentence by mathematical induction. Concerning the base case ($n = 0_C$), we notice that

$$0_C \in u_C(0_C) \quad [= \{0_C, \ldots, n\}]$$

holds with (4.83). Concerning the induction step, we let n be arbitrary in C and prove the implication

$$n \in \{0_C, \ldots, n\} \Rightarrow s(n) \in \{0_C, \ldots, s(n)\}) \tag{4.94}$$

directly. We make the induction assumption

$$n \in u_C(n) \quad [= \{0_C, \ldots, n\}]$$

and prove

$$s(n) \in u_C(s(n)) \quad [= \{0_C, \ldots, s(n)\}].$$

In view of (4.84), we have

$$u_C(s(n)) = u_C(n) \cup \{s(n)\},$$

where $s(n) \in u_C(n) \cup \{s(n)\}$ holds by definition of the union of a pair. Then, the preceding equation gives the desired $s(n) \in u_C(s(n))$ after substitution. As n was arbitrary, we may therefore conclude that the induction step is true as well. Since C, s and 0_C were initially arbitrary, it follows that the proposition holds, as claimed. □

Note 4.6. Proposition 4.13 shows in particular that every value of u_C is a nonempty set.

Exercise 4.4. Verify for any counting domain $(C, s, 0_C)$ that the initial segment of C up to an $n \in C$ contains the beginning 0_C, i.e.

$$\forall n\,(n \in C \Rightarrow 0_C \in \{0_C, \ldots, n\}). \tag{4.95}$$

(Hint: Proceed in analogy to the proof of Proposition 4.13.)

Corollary 4.14. *The initial segment of* $\mathbb{N}$ *up to a natural number* n *contains* n *and* 0*, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow n \in \{0, \ldots, n\}), \tag{4.96}$$

$$\forall n\,(n \in \mathbb{N} \Rightarrow 0 \in \{0, \ldots, n\}). \tag{4.97}$$

Note 4.7. Since $u_{\mathbb{N}}(n) = s^+(n) = n^+$ holds for any $n \in \mathbb{N}$, the sentences (4.96) and (4.97) are equivalent to the previously found sentences (2.305 and (2.319).

Proposition 4.15. *The following sentences are true for any counting domain* $(C, s, 0_C)$*.*

a) If the successor of an $m \in C$ *is element of the initial segment of* C *up to an* $n \in C$*, then* m *is also element of this initial segment, i.e.*

$$\forall m, n\,(m, n \in C \Rightarrow [s(m) \in \{0_C, \ldots, n\} \Rightarrow m \in \{0_C, \ldots, n\}]). \tag{4.98}$$

b) The successor of an $n \in C$ *is not an element of the initial segment of* C *up to* n*, i.e.*

$$\forall n\,(n \in C \Rightarrow s(n) \notin \{0_C, \ldots, n\}). \tag{4.99}$$

c) If an $m \in C$ is element of the initial segment of C up to an $n \in C$ where m and n are different, then the successor of m is also element of this initial segment, i.e.

$$\begin{aligned}&\forall m, n\,(m, n \in C \Rightarrow \\ &\quad [(m \neq n \,\wedge\, m \in \{0_C, \ldots, n\}) \Rightarrow s(m) \in \{0_C, \ldots, n\}]).\end{aligned} \tag{4.100}$$

d) The function u_C is an injection, i.e.

$$\forall m, n\,(m, n \in C \Rightarrow [\{0_C, \ldots, m\} = \{0_C, \ldots, n\} \Rightarrow m = n]). \tag{4.101}$$

e) If the initial segment of C up to an $m \in C$ is a proper subset of the initial segment of C up to an $n \in C$, then the initial segment of C up to the successor of m is included in the initial segment of C up to n, i.e.

$$\begin{aligned}&\forall m, n\,([m, n \in C \Rightarrow \\ &\quad [\{0_C, \ldots, m\} \subset \{0_C, \ldots, n\} \Rightarrow \{0_C, \ldots, s(m)\} \subseteq \{0_C, \ldots, n\}]).\end{aligned} \tag{4.102}$$

f) The initial segment of C up to any $n \in C$ is a proper subset of the initial segment of C up to the successor of n, i.e.

$$\forall n\,(n \in C \Rightarrow \{0_C, \ldots, n\} \subset \{0_C, \ldots, s(n)\}). \tag{4.103}$$

Proof. We let $(C, s, 0_C)$ be an arbitrary counting domain and $u_C : C \to \mathcal{P}(C)$ the function satisfying (4.83) and (4.84).

Concerning a), let us rewrite (4.98) equivalently as

$$\forall m\,(m \in C \Rightarrow \forall n\,(n \in C \Rightarrow [s(m) \in u_C(n) \Rightarrow m \in u_C(n)])) \tag{4.104}$$

using Exercise 1.16. Now, we let m be arbitrary, assume $m \in C$, and carry out a proof by mathematical induction with respect to n. Concerning the base case ($n = 0_C$), we prove the implication

$$s(m) \in u_C(0_C) \Rightarrow m \in u_C(0_C). \tag{4.105}$$

The antecedent $s(m) \in u_C(0_C)$ is equivalent to $s(m) \in \{0_C\}$ due to (4.83); the latter is also equivalent to $s(m) = 0_C$ because of (2.169). By Property 1 of a counting domain, $s(m) = 0_C$ is false, so that the equivalent antecedent $s(m) \in u_C(0_C)$ is also false. Therefore, the implication (4.105) is true. Concerning the induction step, we let n be arbitrary in C, make the induction assumption

$$s(m) \in u_C(n) \Rightarrow m \in u_C(n), \tag{4.106}$$

and show that this implies

$$s(m) \in u_C(s(n)) \Rightarrow m \in u_C(s(n)). \tag{4.107}$$

To prove this implication directly, we assume $s(m) \in u_C(s(n))$, which implies $s(m) \in u_C(n) \cup \{s(n)\}$ with (4.84), and therefore

$$s(m) \in u_C(n) \,\vee\, s(m) \in \{s(n)\} \tag{4.108}$$

by definition of the union of two sets. We now use this true disjunction to prove the sentence $m \in u_C(n)$ by cases. If $s(m) \in u_C(n)$ is true, then it follows with the induction assumption (4.106) that $m \in u_C(n)$. If $s(m) \in \{s(n)\}$ holds, then it follows with (2.169) that $s(m) = s(n)$, which implies $m = n$ with Property 2 of a counting domain; in view of Proposition 4.13, $n \in u_C(n)$ is true and then after substitution also $m \in u_C(n)$. Thus, the proof of $m \in u_C(n)$ by cases is complete. This finding evidently implies the disjunction $m \in u_C(n) \vee m \in \{s(n)\}$ (no matter if $m \in \{s(n)\}$ is true or false), and therefore $m \in u_C(n) \cup \{s(n)\}$ (by definition of the union of two sets). Due to (4.84), this means $m \in u_C(s(n))$, which proves the implication (4.107). As n is arbitrary, we therefore conclude that the induction step is true, which completes the proof by mathematical induction. Since m was also arbitrary, we may further conclude that (4.104) holds, so that the proof of (4.98) is complete.

Concerning b), we carry out a proof by mathematical induction. Regarding the base case ($n = 0_C$), we prove $s(0_C) \notin u_C(0_C)$. By Property 1 of a counting domain, we have $s(0_C) \neq 0_C$ and therefore $s(0_C) \notin \{0_C\}$ with (2.169). Using (4.83), we obtain the desired $s(0_C) \notin u_C(0_C)$. Regarding the induction step

$$\forall n\, (n \in C \Rightarrow [s(n) \notin u_C(n) \Rightarrow s(s(n)) \notin u_C(s(n))]), \tag{4.109}$$

we let $n \in C$ be arbitrary and prove the inner implication by contradiction, assuming

$$s(n) \notin u_C(n) \,\wedge\, s(s(n)) \in u_C(s(n)). \tag{4.110}$$

Due to (4.84), this conjunction is equivalent to

$$s(n) \notin u_C(n) \,\wedge\, s(s(n)) \in u_C(n) \cup \{s(n)\}$$

and then also to (applying the definition of the union of a pair)

$$s(n) \notin u_C(n) \,\wedge\, [s(s(n)) \in u_C(n) \,\vee\, s(s(n)) \in \{s(n)\}].$$

An application of the Distributive Law for sentences (1.44) then gives the equivalently true

$$[s(n) \notin u_C(n) \wedge s(s(n)) \in u_C(n)] \vee [s(n) \notin u_C(n) \wedge s(s(n)) \in \{s(n)\}]. \tag{4.111}$$

Next, we use this true disjunction to prove the sentence $s(n) \in u_C(n)$ by cases. In case

$$s(n) \notin u_C(n) \wedge s(s(n)) \in u_C(n)$$

is true, then it follows in particular that $s(s(n)) \in u_C(n)$ holds, which in turn implies the desired $s(n) \in u_C(n)$ with (4.98). In the other case that the second part

$$s(n) \notin u_C(n) \wedge s(s(n)) \in \{s(n)\}$$

of the disjunction (4.111) is true, it follows in particular that $s(s(n)) \in \{s(n)\}$ holds, and this yields $s(s(n)) = s(n)$ with (2.169). This equation implies by Property 2 of a counting domain $s(n) = n$, so that the fact $n \in u_C(n)$ from Proposition 4.13 gives via substitution $s(n) \in u_C(n)$ once again, completing the proof by cases. Let us now observe that this sentence's negation $s(n) \notin u_C(n)$ is also true in view of the assumed conjunction (4.110). We thus obtained a contradiction, which completes the proof of the inner implication in (4.109), and then also the direct proof of the outer implication (based on the antecedent $n \in C$). As n was arbitrary, we may therefore conclude that the induction step (4.109) holds besides the base case, so that the proof of (4.99) via methematical induction is complete.

Concerning c), we first rewrite (4.100) equivalently as

$$\forall m\,(m \in C \Rightarrow \forall n\,(n \in C \Rightarrow [(m \neq n \wedge m \in u_C(n)) \Rightarrow s(m) \in u_C(n)])). \tag{4.112}$$

by applying Exercise 1.16, let then m be arbitrary in C, and apply a proof by mathematical induction with respect to n. Regarding the base case ($n = 0_C$), we prove the implication

$$[m \neq 0_C \wedge m \in u_C(0_C)] \Rightarrow s(m) \in u_C(0_C). \tag{4.113}$$

Here, we obtain the equivalences

$$m \in u_C(0_C) \Leftrightarrow m \in \{0_C\} \Leftrightarrow m = 0_C$$

with (4.83) and (2.169); according to the Substitution Rule for conjunctions (1.22), the conjunction in (4.113) follows then to be equivalent to the contradiction $m \neq 0_C \wedge m = 0_C$, so that the antecedent of the implication (4.113) is also false. Thus, this implication is true (no matter if the consequent is true or false), which proves the base case.

Regarding the induction step, we let n be arbitrary in C, make the induction assumption

$$[m \neq n \wedge m \in u_C(n)] \Rightarrow s(m) \in u_C(n), \tag{4.114}$$

and prove

$$[m \neq s(n) \wedge m \in u_C(s(n))] \Rightarrow s(m) \in u_C(s(n)). \tag{4.115}$$

We now obtain the true equivalences

$$\begin{aligned}
& m \neq s(n) \wedge m \in u_C(s(n)) \\
& \quad \Leftrightarrow m \neq s(n) \wedge m \in u_C(n) \cup \{s(n)\} \\
& \quad \Leftrightarrow m \neq s(n) \wedge [m \in u_C(n) \vee m \in \{s(n)\}] \\
& \quad \Leftrightarrow m \neq s(n) \wedge [m \in u_C(n) \vee m = s(n)] \\
& \quad \Leftrightarrow [m \neq s(n) \wedge m \in u_C(n)] \vee [m \neq s(n) \wedge m = s(n)] \\
& \quad \Leftrightarrow [m \neq s(n) \wedge m \in u_C(n)]
\end{aligned}$$

using the definition of an initial segment, the definition of the union of a pair, (2.169), the Distributive Law for sentences (1.44), and finally the Contradiction Law in connection with the evident fact that the conjunction $m \neq s(n) \wedge m = s(n)$ is a contradiction. In view of the Substitution Rule for implications (1.26), we may therefore prove the implication

$$[m \neq s(n) \wedge m \in u_C(n)] \Rightarrow s(m) \in u_C(s(n)) \tag{4.116}$$

equivalently to (4.115). We do this by considering the two exhaustive cases $m = n$ and $m \neq n$. In the first case, we assume the conjunction of $m \neq s(n)$, $m \in u_C(n)$ and $m = n$. Since $s(n) \in u_C(s(n))$ is true because of Proposition 4.13 (using the fact that $s(n) \in C$ holds by definition of the function s), it then follows with $m = n$ that $s(m) \in u_C(s(n))$. In the second case, we assume the conjunction of $m \neq s(n)$, $m \in u_C(n)$ and $m \neq n$. The second and third part imply with the induction assumption (4.114) that $s(m) \in u_C(n)$ holds, which then further implies the disjunction $s(m) \in u_C(n) \vee s(m) \in \{s(n)\}$ (no matter if $s(m) \in \{s(n)\}$ is true or not), and therefore $s(m) \in u_C(n) \cup \{s(n)\}$ (applying the definition of the union of a pair), so that $s(m) \in u_C(s(n))$ follows to be true by definition of an initial segment. Thus, $s(m) \in u_C(s(n))$ holds in any case, which proves the implication (4.116), and thus (4.116). As n is arbitrary, we therefore conclude that the induction step holds, which completes the proof by mathematical induction. Since m was also arbitrary, we then further conclude that (4.112) is true, which completes the proof of (4.100).

Concerning d), we let m and n be arbitrary in C and prove then the implication $u_C(m) = u_C(n) \Rightarrow m = n$ by contradiction. To do this, we assume $u_C(m) = u_C(n)$ and $m \neq n$. Recalling that $n \in u_C(n)$ holds with Proposition 4.13, we obtain $n \in u_C(m)$ with the assumed equation. On the one hand, the conjunction of the assumption $n \neq m$ and $n \in u_C(m)$ implies $s(n) \in u_C(m)$ with the previously established (4.100); on the other hand, the fact that $s(n) \notin u_C(n)$ is true in view of (4.99) implies – together with the assumed equation $u_C(m) = u_C(n)$ – that $s(n) \notin u_C(m)$ holds, which contradicts the previously obtained $s(n) \in u_C(m)$. This proves the stated implication, and since m as well as n was arbitrary, we my therefore conclude that (4.101) is true.

Concerning e), we let m and n be arbitrary in C and prove the implication

$$u_C(m) \subset u_C(n) \Rightarrow u_C(s(m)) \subseteq u_C(n) \tag{4.117}$$

directly, assuming $u_C(m) \subset u_C(n)$, which means by definition of a proper subset (in connection with the definition of a subset)

$$\forall k\,(k \in u_C(m) \Rightarrow k \in u_C(n)) \,\wedge\, u_C(m) \neq u_C(n). \tag{4.118}$$

To show that this implies $u_C(s(m)) \subseteq u_C(n)$, which is equivalent to

$$\forall k\,(k \in u_C(s(m)) \Rightarrow k \in u_C(n)) \tag{4.119}$$

by definition of a subset, we let k be arbitrary and prove the implication in (4.119) directly, which is equivalent to the original implication (4.117) according to the Substitution rule for implications (1.27). To do this, we assume $k \in u_C(s(m))$, which implies $k \in u_C(m) \cup \{s(m)\}$ by definition of an initial segment, and therefore

$$k \in u_C(m) \vee k \in \{s(m)\} \tag{4.120}$$

by definition of the union of a pair. We now use this true disjunction to prove the desired consequent $k \in u_C(n)$ by cases. In case $k \in u_C(m)$ is true, then this implies the desired $k \in u_C(n)$ with the first part of the assumed conjunction (4.118). If the second part $k \in \{s(m)\}$ of the disjunction (4.120) is true, then this implies $k = s(m)$ with (2.169); since u_C is a function, the second part $u_C(m) \neq u_C(n)$ of the assumed conjunction (4.118) implies $m \neq n$ with Proposition 3.149. Furthermore, the fact that $m \in u_C(m)$ holds due to Proposition 4.13 implies $m \in u_C(n)$ with the first part of the assumed conjunction (4.118). Now, the conjunction of these findings $m \neq n$ and $m \in u_C(n)$ implies with (4.100) that $s(m) \in u_C(n)$ holds, so that substitution based on the previously found equation $k = s(m)$ yields $k \in u_C(n)$, as desired. Thus, the proof by cases of $k \in u_C(n)$ is complete, and this finding proves the implication in (4.119). As k is arbitrary, we therefore conclude that (4.119) is true, which means that $u_C(s(m)) \subseteq u_C(n)$ holds. This in turn proves the implication (4.117), and since m and n were arbitrary, we then conclude that (4.102) holds, as claimed.

Concerning f), we let n be arbitrary in C. In view of (2.201) in connection with the definition of a pair we see on the one hand that $u_C(n) \subseteq u_C(n) \cup \{s(n)\}$ holds, and therefore $u_C(n) \subseteq u_C(s(n))$ using the definition of an initial segment. On the other hand, the fact that $n \neq s(n)$ holds with Proposition 4.3 implies $u_C(n) \neq u_C(s(n))$ with the Injection Criterion and the previously established fact (4.101) that u_C is an injection. Consequently, $u_C(n) \subset u_C(s(n))$ holds by definition of a proper subset. As n was arbitrary, we therefore conclude that (4.103) is true.

Since C, s and 0_C were arbitrary in the proofs of the sentences a) – f), we may infer from these the truth of the proposition. □

We now derive from the preceding proposition the particular results for the counting domain $(\mathbb{N}, s^+, 0)$, where we use the two notations n^+ and $\{0, \ldots, n\}$ for the initial segment $u_{\mathbb{N}}(n)$ according to (4.92).

Corollary 4.16. *The following sentences are true for the counting domain* $(\mathbb{N}, s^+, 0)$.

a) *If the successor of a natural number m is element of the initial segment of $\mathbb{N}$ up to a natural number n, then m is also element of this initial segment, i.e.*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m^+ \in \{0, \ldots, n\} \Rightarrow m \in \{0, \ldots, n\}]). \quad (4.121)$$

In other words, if the successor of a natural number m is element of the successor of a natural number n, then m is also element of that successor, i.e.

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m^+ \in n^+ \Rightarrow m \in n^+]). \quad (4.122)$$

b) *The successor of a natural number n is not an element of the initial segment of $\mathbb{N}$ up to n, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \notin \{0, \ldots, n\}). \quad (4.123)$$

In other words, the successor of a natural number n is not an element of itself, i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \notin n^+). \quad (4.124)$$

c) If a natural number m is element of the initial segment of $\mathbb{N}$ up to a natural number n where m and n are different, then the successor of m is also element of this initial segment, i.e.

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [(m \neq n \wedge m \in \{0, \ldots, n\}) \Rightarrow m^+ \in \{0, \ldots, n\}]). \tag{4.125}$$

In other words, if a natural number m is element of the successor of a natural number n where m and n are different, then the successor of m is also element of the successor of n, i.e.

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [(m \neq n \wedge m \in n^+) \Rightarrow m^+ \in n^+]). \tag{4.126}$$

d) The function $u_{\mathbb{N}}$ is an injection, i.e.

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [\{0, \ldots, m\} = \{0, \ldots, n\} \Rightarrow m = n]). \tag{4.127}$$

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m^+ = n^+ \Rightarrow m = n]). \tag{4.128}$$

e) If the initial segment of $\mathbb{N}$ up to a natural number m is a proper subset of the initial segment of $\mathbb{N}$ up to a natural number n, then the initial segment of $\mathbb{N}$ up to the successor of m is included in the initial segment of $\mathbb{N}$ up to n, i.e.

$$\begin{aligned}&\forall m, n\,([m, n \in \mathbb{N} \Rightarrow \\ &\quad [\{0, \ldots, m\} \subset \{0, \ldots, n\} \Rightarrow \{0, \ldots, m^+\} \subseteq \{0, \ldots, n\}]).\end{aligned} \tag{4.129}$$

In other words, if the successor of a natural number m is a proper subset of the successor of a natural number n, then the successor of m^+ is included in the successor of n, i.e.

$$\forall m, n\,([m, n \in \mathbb{N} \Rightarrow [m^+ \subset n^+ \Rightarrow m^{++} \subseteq n^+]). \tag{4.130}$$

f) The initial segment of $\mathbb{N}$ up to any natural number n is a proper subset of the initial segment of $\mathbb{N}$ up to the successor of n, i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow \{0, \ldots, n\} \subset \{0, \ldots, n^+\}). \tag{4.131}$$

In other words, the successor of any natural number n is a proper subset of the successor of n^+, i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow n^+ \subset n^{++}). \tag{4.132}$$

Note 4.8. We already stated (4.128) in (4.36) and proved this sentence as part of Theorem 4.6 independently from the results of Proposition 4.15.

We may now use the recursion equation (4.86) and the preceding proposition to find further relationships for initial segments.

Proposition 4.17. *The following sentences are true for any counting domain* $(C, s, 0_C)$*.*

a) The initial segment of C *up to an* $n \in C$ *and the singleton formed by the successor of* n *are disjoint, that is,*

$$\forall n\,(n \in C \Rightarrow \{0_C, \ldots, n\} \cap \{s(n)\} = \emptyset). \tag{4.133}$$

b) The initial segment of C *up to an* $n \in C$ *equals the difference of the initial segment of* C *up to the successor of* n *and the singleton formed by that successor, that is,*

$$\forall n\,(n \in C \Rightarrow \{0_C, \ldots, n\} = \{0_C, \ldots, s(n)\} \setminus \{s(n)\}). \tag{4.134}$$

c) The singleton formed by the successor of an $n \in C$ *equals the difference of the initial segment of* C *up to the successor of* n *and the initial segment up to* n*, i.e.*

$$\forall n\,(n \in C \Rightarrow \{s(n)\} = \{0_C, \ldots, s(n)\} \setminus \{0_C, \ldots, n\}). \tag{4.135}$$

Proof. We let $(C, s, 0_C)$ be an arbitrary counting domain. Concerning a), we let n be arbitrary and prove the implication by contradiction, assuming $n \in C$ and $\{0_C, \ldots, n\} \cap \{s(n)\} \neq \emptyset$ to be true. The latter implies with Proposition 2.11 that there exists an element in $\{0_C, \ldots, n\} \cap \{s(n)\}$, say $\bar{m}$. Then, $\bar{m} \in \{0_C, \ldots, n\}$ and $\bar{m} \in \{s(n)\}$ are both true by definition of the intersection of two sets. Here, $\bar{m} \in \{s(n)\}$ implies $\bar{m} = s(n)$ with (2.169); applying now substitution based on this equation, the previously established $\bar{m} \in \{0_C, \ldots, n\}$ gives $s(n) \in \{0_C, \ldots, n\}$, which evidently contradicts the fact $s(n) \notin \{0_C, \ldots, n\}$ resulting from (4.99). Thus, the proof of the implication (4.133) via contradiction is complete, and since n was arbitrary, we may therefore conclude that b) is true.

Concerning b), we let $n \in C$ be arbitrary and observe in light of (2.262) that the conjunction of the equations in (4.86) and (4.133) implies the equation in (4.134). As n is arbitrary, we may therefore further conclude that c) also holds.

Finally, concerning c), we again let $n \in C$ be arbitrary. On the one hand, we may apply the Commutative Law for the union of two sets in connection with the equation in (4.86) to obtain the true equation

$$\{0_C, \ldots, s(n)\} = \{s(n)\} \cup \{0_C, \ldots, n\}. \tag{4.136}$$

On the other hand, we obtain from the equation in (4.133) with the Commutative Law for the intersection of two sets the equivalent equation

$$\{s(n)\} \cap \{0_C, \ldots, n\} = \emptyset. \tag{4.137}$$

Then, we may again employ (2.262) to infer from the truth of (4.136) and of (4.137) the truth of the equation in (4.135). Since n is arbitrary, d) follows then to be true as well.

As C, s and 0_C were initially arbitrary, we may finally conclude that the proposition holds, as claimed. □

Corollary 4.18. *The following sentences are true for the counting domain* $(\mathbb{N}, s^+, 0)$.

a) The initial segment of N up to a natural number n and the singleton formed by the successor of n are disjoint, that is,

$$\forall n\, (n \in \mathbb{N} \Rightarrow \{0, \ldots, n\} \cap \{n^+\} = \emptyset). \tag{4.138}$$

b) The initial segment of N up to a natural number n equals the difference of the initial segment up to the successor of n and the singleton formed by that successor, that is,

$$\forall n\, (n \in \mathbb{N} \Rightarrow \{0, \ldots, n\} = \{0, \ldots, n^+\} \setminus \{n^+\}). \tag{4.139}$$

c) The singleton formed by the successor of a natural number n equals the difference of the initial segment of N up to the successor of n and the initial segment of N up to n, that is,

$$\forall n\, (n \in \mathbb{N} \Rightarrow \{n^+\} = \{0, \ldots, n^+\} \setminus \{0, \ldots, n\}). \tag{4.140}$$

4.3. Linearly Ordered Sets $(C, <_C)$ and the Linearly Ordered Set $(\mathbb{N}, <_{\mathbb{N}})$

Recalling that the binary relation $\subseteq$ may be used to define a reflexive partial ordering of an arbitrary set system, it is now used in connection with the initial segments of a counting set to define a reflexive partial ordering of that counting set. This ordering turns out to be total, so that the induced irreflexive partial ordering is linear.

Theorem 4.19 (Total & linear ordering of a counting set). *The following sentences are true for any counting domain $(C, s, 0_C)$.*

a) There exists a unique set $\leq_C$ consisting of all ordered pairs (m, n) satisfying $u_C(m) \subseteq u_C(n)$. This set $\leq_C$ is a binary relation satisfying

$$\forall m, n\,(m, n \in C \Rightarrow [m \leq_C n \Leftrightarrow \{0_C, \ldots, m\} \subseteq \{0_C, \ldots, n\}]) \tag{4.141}$$

and is furthermore a total ordering of C.

b) Moreover, the linear ordering $<_C$ of C induced by $\leq_C$ satisfies

$$\forall n\,(n \in C \Rightarrow n <_C s(n)). \tag{4.142}$$

Proof. We let C, s and 0_C be arbitrary and assume that $(C, s, 0_C)$ is a counting domain. Concerning a), we recall from the definition of an initial segment that the domain of u_C equals C, so that every ordered pair (m, n) satisfying $u_C(m) \subseteq u_C(n)$ is an element of the Cartesian product $C \times C$. We may therefore apply the Axiom of Specification together with the Equality Criterion for sets to obtain the true sentence

$$\begin{aligned}&\exists!\, \leq_C\ \forall Y\,(Y \in \leq_C \\ &\quad \Leftrightarrow [Y \in C \times C\ \wedge\ \exists m, n\,(u_C(m) \subseteq u_C(n)\ \wedge\ (m, n) = Y)]).\end{aligned}$$

Thus, the set $\leq_C$ satisfies

$$\forall Y\,(Y \in \leq_C \Leftrightarrow [Y \in C \times C\ \wedge\ \exists m, n\,(u_C(m) \subseteq u_C(n)\ \wedge\ (m, n) = Y)]). \tag{4.143}$$

Let us now check that $\leq_C$ is a subset of $C \times C$, i.e. that

$$\forall Y\,(Y \in \leq_C \Rightarrow Y \in C \times C)$$

holds by definition of a subset. Letting Y be arbitrary, we see that $Y \in \leq_C$ implies the conjunction of $Y \in C \times C$ and the existential sentence in (4.143), so that $Y \in \leq_C$ implies in particular $Y \in C \times C$. Then, as Y is arbitrary, we conclude that $\leq_C \subseteq C \times C$ holds indeed. Thus, $\leq_C$ is a binary relation on C, which we now demonstrate to satisfy (4.141). We let m and n be arbitrary in C and prove the first part ('$\Rightarrow$') of the equivalence directly by assuming $m \leq_C n$. This implies with (4.143) in particular that there exist constants, say $\bar{m}$ and $\bar{n}$, such that $u_C(\bar{m}) \subseteq u_C(\bar{n})$ and $(\bar{m}, \bar{n}) = (m, n)$ hold. In view of the Equality Criterion for ordered pairs, the preceding equation implies $\bar{m} = m$ and $\bar{n} = n$. With these equations, it follows after substitution in $u_C(\bar{m}) \subseteq u_C(\bar{n})$ that $u_C(m) \subseteq u_C(n)$ holds, which is the desired consequent of the first part of the equivalence. To prove the second part ('$\Leftarrow$'), we now assume $u_C(m) \subseteq u_C(n)$. Denoting the ordered pair (m, n) by Y, we then see that the existential sentence

$$\exists m, n\,(u_C(m) \subseteq u_C(n) \,\wedge\, (m, n) = Y)$$

is true, and furthermore that $[(m, n) =]\ Y \in C \times C$ holds due to $m, n \in C$ and the definition of a Cartesian product. It then follows with (4.143) that $Y \in\ \leq_C$, which means $m \leq_C n$. Since m and n were arbitrary, we therefore conclude that $\leq_C$ satisfies indeed (4.141).

Next, we prove that the binary relation $\leq_C$ on C is a total ordering. We begin with the verification that $\leq_C$ is reflexive, i.e.

$$\forall a\,(a \in C \Rightarrow a \leq_C a). \tag{4.144}$$

For this purpose, we let a be arbitrary in C and observe from (4.141) that $a \leq_C a$ is equivalent to $u_C(a) \subseteq u_C(a)$. We already know from Theorem 3.64 that $\subseteq$ is a reflexive partial ordering of any set system, in particular of $\mathcal{P}(C)$, so that $u_C(a) \subseteq u_C(a)$ is true. Thus, $a \leq_C a$ also holds, and since a was arbitrary, we therefore conclude that (4.144) is true, which means that $\leq_C$ is reflexive.

To prove that $\leq_C$ is antisymmetric, that is,

$$\forall a, b\,(a, b \in C \Rightarrow [(a \leq_C b \,\wedge\, b \leq_C a) \Rightarrow a = b]), \tag{4.145}$$

we let a and b be arbitrary in C and assume $a \leq_C b$ as well as $b \leq_C a$. Because of (4.141) the assumptions mean that $u_C(a) \subseteq u_C(b)$ and $u_C(b) \subseteq u_C(a)$. We already established $\subseteq$ as a reflexive partial ordering, so that $\subseteq$ is antisymmetric, which yields $u_C(a) = u_C(b)$ (this equation follows also directly with the Axiom of Extension). This equation implies $a = b$ with (4.101); as a and b are arbitrary, we therefore conclude that (4.145) holds, so that $\leq_C$ is also antisymmetric.

We now show that $\leq_C$ is transitive, i.e. that $\leq_C$ that satisfies

$$\forall a, b, c\,(a, b, c \in C \Rightarrow [(a \leq_C b \,\wedge\, b \leq_C c) \Rightarrow a \leq_C c]). \tag{4.146}$$

Letting a, b, c be arbitrary in C and assuming both $a \leq_C b$ and $b \leq_C c$ to be true, it follows with (4.141) that the conjunction of $u_C(a) \subseteq u_C(b)$ and $u_C(b) \subseteq u_C(c)$ holds, which implies $u_C(a) \subseteq u_C(c)$ with the transitivity of the reflexive partial ordering $\subseteq$ (see also Proposition 2.5). The latter then implies the desired $a \leq_C c$ (applying once again (4.141)). Since a, b, c were arbitrary, we conclude that (4.146) is true, which means that $\leq_C$ is indeed transitive.

Thus, as a reflexive, antisymmetric and transitive binary relation on C, $\leq_C$ is a reflexive partial ordering of C. We now verify that $\leq_C$ is also total, i.e.

$$\forall a, b\,(a, b \in C \Rightarrow [a \leq_C b \,\vee\, b \leq_C a]),$$

by proving the equivalent (using Exercise 1.16)

$$\forall a\,(a \in C \Rightarrow \forall b\,(b \in C \Rightarrow [a \leq_C b \,\vee\, b \leq_C a])). \tag{4.147}$$

We let a be arbitrary in C and carry out a proof by mathematical induction with respect to b. Concerning the base case ($b = 0_C$), we prove that $a \leq_C 0_C$ or $0_C \leq_C a$ is true. Since $0_C \in u_C(a)$ holds with Exercise 4.4 and therefore $\{0_C\} \subseteq u_C(a)$ with with (2.184), we obtain with the equation $u_C(0_C) = \{0_C\}$ in (4.83) after substitution $u_C(0_C) \subseteq u_C(a)$. This implies $0_C \leq_C a$ with (4.141)), so that the disjunction of $0_C \leq_C a$ and $a \leq_C 0_C$ holds as well (no matter if $a \leq_C 0_C$ is true or not), which proves the base case. Regarding the induction step, we let b be an arbitrary element of C, make the induction assumption $a \leq_C b \vee b \leq_C a$, and use this true disjunction to prove

$$a \leq_C s(b) \,\vee\, s(b) \leq_C a \tag{4.148}$$

by cases.

On the one hand, if $a \leq_C b$ holds, then also $u_C(a) \subseteq u_C(b)$ because of (4.141)). Since $u_C(b) \subseteq u_C(b) \cup \{s(b)\}$ also holds in view of (2.201), where $u_C(b) \cup \{s(b)\} = u_C(s(b))$ according to (4.84), we obtain from $u_C(a) \subseteq u_C(b) \subseteq u_C(s(b))$ with the transitivity of $\subseteq$ that $u_C(a) \subseteq u_C(s(b))$. This implies $a \leq_C s(b)$ with (4.141)) and then also the disjunction (4.148) (no matter if $s(b) \leq_C a$ is true or false).

On the other hand, if the second part $b \leq_C a$ of the induction assumption is true, then also $u_C(b) \subseteq u_C(a)$ due to (4.141), so that the disjunction $u_C(b) \subset u_C(a) \vee u_C(b) = u_C(a)$ holds (see Proposition 2.8). Let us now use this true disjunction to prove (4.148) by cases. In case $u_C(b) \subset u_C(a)$ is true, then it follows with (4.102) that $u_C(s(b)) \subseteq u_C(a)$. Consequently, $s(b) \leq_C a$ is true, and therefore also the disjunction (4.148) (no matter if $a \leq_C s(b)$ is true or false). In the other case that $u_C(b) = u_C(a)$ is true, the disjunction $u_C(a) \subset u_C(b) \vee u_C(a) = u_C(b)$ holds also (no matter if

$u_C(a) \subset u_C(b)$ is true or false), so that we obtain $u_C(a) \subseteq u_C(b)$ (using again Proposition 2.8), which we already showed in the case $a \leq_C b$ to imply (4.148).

Thus, the two nested proofs by cases are complete (4.148), and since b was arbitrary, we therefore conclude that the induction step is true. This completes the proof by mathematical induction, and as a is also arbitrary, we further conclude that (4.147) holds, so that $\leq_C$ is a total binary relation. Thus, $\leq_C$ is a total ordering of C.

Concerning b), since $(C, \leq_C)$ is a totally ordered set, it follows with Theorem 3.86 that there exists the induced binary relation $<_C$, which is a linear ordering of C because of Theorem 3.89. We now show that $<_C$ satisfies

$$\forall n \, (n \in C \Rightarrow (n, s(n)) \in {<_C}). \tag{4.149}$$

For this purpose, we let n be arbitrary in C and observe that $u_C(n) \subseteq u_C(n) \cup \{s(n)\}$ and therefore $u_C(n) \subseteq u_C(s(n))$ holds (using Proposition 2.67 and (4.84)). It then follows with (4.141) that $n \leq_C s(n)$. We furthermore have $s(n) \neq n$ with Proposition 4.3, so that the conjunction $n \leq_C s(n) \wedge n \neq s(n)$ holds. We now define the ordered pair $u = (n, s(n))$, which is an element of $C \times C$ by definition of the successor function s. Thus, there exist a, b with $a \leq_C b$, $a \neq b$, and $(a, b) = u$. The conjunction of this existential sentence and the previously established $u \in C \times C$ then implies $u \in {<_C}$ with (3.254), which means that $(n, s(n)) \in {<_C}$ holds. As n is arbitrary, we therefore conclude that (4.149) is true, completing the proof of b).

Since C, s and 0_C were arbitrary, we may finally infer from these findings the truth of the stated theorem. □

Theorem 4.20 (Characterization of the linear ordering of a counting set). *For any counting domain $(C, s, 0_C)$ the linear ordering $<_C$ of C induced by $\leq_C$ satisfies*

$$\forall m, n \, (m, n \in C \Rightarrow [m <_C n \Leftrightarrow \{0_C, \ldots, m\} \subset \{0_C, \ldots, n\}]). \tag{4.150}$$

Proof. We let C, s and 0_C be arbitrary, assume that $(C, s, 0_C)$ is a counting domain, let $m, n \in C$ be arbitrary, and observe the truth of the equivalences

$$\begin{aligned} m <_C n \;&\Leftrightarrow\; m \leq_C n \,\wedge\, m \neq n \\ &\Leftrightarrow\; \{0_C, \ldots, m\} \subseteq \{0_C, \ldots, n\} \,\wedge\, m \neq n \\ &\Leftrightarrow\; \{0_C, \ldots, m\} \subseteq \{0_C, \ldots, n\} \,\wedge\, u_C(m) \neq u_C(n) \\ &\Leftrightarrow\; \{0_C, \ldots, m\} \subseteq \{0_C, \ldots, n\} \,\wedge\, \{0_C, \ldots, m\} \neq \{0_C, \ldots, n\} \\ &\Leftrightarrow\; \{0_C, \ldots, m\} \subset \{0_C, \ldots, n\} \end{aligned}$$

in light of (3.252), (4.141), Corollary 3.186 in connection with Proposition 4.15d), the definition of an initial segment, and the definition of a proper subset. Since m and n were arbitrary, we may therefore conclude that the universal sentence (4.150) is true, and as C, s and 0_C were also arbitrary, we may then infer from this the truth of the stated theorem. $\square$

Definition 4.3 (Standard total & linear ordering of a counting set). For any counting domain $(C, s, 0_C)$ we call $\leq_C$ the *standard total ordering of* C and $<_C$ the *standard linear ordering of* C.

We now state the findings of Theorem 4.19 and of Theorem 4.20 specifically for the counting domain of natural numbers.

Corollary 4.21. *The following sentences are true for the counting domain* $(\mathbb{N}, s^+, 0)$.

a) The total ordering $\leq_\mathbb{N}$ *of* $\mathbb{N}$ *(defined according to Theorem 4.19) satisfies*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \leq_\mathbb{N} n \Leftrightarrow \{0, \ldots, m\} \subseteq \{0, \ldots, n\}]), \tag{4.151}$$

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \leq_\mathbb{N} n \Leftrightarrow m^+ \subseteq n^+]), \tag{4.152}$$

and moreover

$$\forall n\,(n \in \mathbb{N} \Rightarrow n <_\mathbb{N} n^+). \tag{4.153}$$

b) Then, the linear ordering $<_\mathbb{N}$ *of* $\mathbb{N}$ *induced by* $\leq_\mathbb{N}$ *satisfies*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m <_\mathbb{N} n \Leftrightarrow \{0, \ldots, m\} \subset \{0, \ldots, n\}]), \tag{4.154}$$

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m <_\mathbb{N} n \Leftrightarrow m^+ \subset n^+]). \tag{4.155}$$

Definition 4.4 (Standard total & linear ordering of $\mathbb{N}$). We call $\leq_\mathbb{N}$ the *standard total ordering of* $\mathbb{N}$ and $<_\mathbb{N}$ the *standard linear ordering of* $\mathbb{N}$.

Notation 4.3. Whenever the context is unambiguous, we will also write $\leq$ instead of $\leq_\mathbb{N}$ and $<$ instead of $<_\mathbb{N}$.

Exercise 4.5. Verify for any counting domain $(C, s, 0_C)$ that, if an $m \in C$ is less than an $n \in C$, then the successor of m is less than or equal to n, i.e.

$$\forall m, n\,(m, n \in C \Rightarrow [m <_C n \Rightarrow s(m) \leq_C n]) \tag{4.156}$$

(Hint: Use Theorem 4.20, Proposition 4.15e), and Theorem 4.19a).)

Corollary 4.22. *The following sentence is true for the counting domain* $(\mathbb{N}, s^+, 0)$.

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m <_\mathbb{N} n \Rightarrow m^+ \leq_\mathbb{N} n]) \tag{4.157}$$

Exercise 4.6. Prove for any counting domain $(C, s, 0_C)$ that, if the successor of an $m \in C$ is less than or equal to the successor of an $n \in C$, then m is less than or equal to n, i.e.

$$\forall m, n\, (m, n \in C \Rightarrow [s(m) \leq_C s(n) \Rightarrow m \leq_C n]). \tag{4.158}$$

(Hint: Apply Method 1.11 in connection with the Negation Formulas for $\leq$ and $<$, (4.156), and Property 3 of a reflexive partial ordering.

Corollary 4.23. *If the successor of a natural number m is less than or equal to the successor of a natural number n, then m is less than or equal to n, that is,*

$$\forall m, n\, (m, n \in \mathbb{N} \Rightarrow [m^+ \leq_{\mathbb{N}} n^+ \Rightarrow m \leq_{\mathbb{N}} n]). \tag{4.159}$$

Proposition 4.24. *For any counting domain $(C, s, 0_C)$ it is true that, if the successor of an $m \in C$ is less than the successor of an $n \in C$, then m is less than n, i.e.*

$$\forall m, n\, (m, n \in C \Rightarrow [s(m) <_C s(n) \Rightarrow m <_C n]). \tag{4.160}$$

Proof. We let C, s and 0_C be arbitrary and assume that $(C, s, 0_C)$ is a counting domain. Next, we let m and n be arbitrary in C and assume $s(m) <_C s(n)$ to be true. The disjunction $s(m) <_C s(n) \vee s(m) = s(n)$ then also holds, which gives with (3.253) $s(m) \leq_C s(n)$, which in turn implies $m \leq_C n$ with (4.158). Moreover, since the linear ordering $<_C$ is comparable, the truth of $s(m) <_C s(n)$ implies $s(m) \neq s(n)$, and then also $m \neq n$ with the fact that s is a function (see Proposition 3.149). We thus showed that $m \leq_C n$ and $m \neq n$ are both true, so that the desired consequent $m <_C n$ follows to be true with (3.252). Since m, n, C, s and 0_C were arbitrary, we may therefore conclude that the stated universal sentence holds, as claimed. □

Corollary 4.25. *If the successor of a natural number m is less than the successor of a natural number n, then m is less than n, that is,*

$$\forall m, n\, (m, n \in \mathbb{N} \Rightarrow [m^+ <_{\mathbb{N}} n^+ \Rightarrow m <_{\mathbb{N}} n]). \tag{4.161}$$

Proposition 4.26. *For any counting domain $(C, s, 0_C)$ and any elements m and n of the counting set, it is true that m is less than or equal to n iff the successor of m is less than or equal to the successor of n, i.e.*

$$\forall m, n\, (m, n \in C \Rightarrow [m \leq_C n \Leftrightarrow s(m) \leq_C s(n)]). \tag{4.162}$$

Proof. Letting C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain and letting $m, n \in C$ be arbitrary, we have on the one hand that the assumption $m \leq_C n$ and the fact $n <_{\mathbb{N}} s(n)$ (see Theorem 4.19b)) imply with the Transitivity Formula for $\leq$ and $<$ the inequality $m <_{\mathbb{N}} s(n)$, which in turn implies $s(m) \leq_C s(n)$ with (4.156). On the other hand, the assumption $s(m) \leq_{\mathbb{N}} s(n)$ implies $m \leq_C n$ with (4.158). Thus, the proposed equivalence is true, which in turn proves the stated implication. Since m and n were arbitrary, the universal sentence (4.162) follows then to be also true, and as C, s and 0_C were initially also arbitrary, we may therefore conclude that the proposition holds, as claimed. □

Corollary 4.27. *For any natural numbers m and n it is true that m is less than or equal to n if, and only if, the successor of m is less than or equal to the successor of n, that is,*

$$\forall m, n\, (m, n \in \mathbb{N} \Rightarrow [m \leq_{\mathbb{N}} n \Leftrightarrow m^+ \leq_{\mathbb{N}} n^+]). \tag{4.163}$$

We are now in a position to state some facts about natural numbers, which we consider to be basic in the remainder of this exposition (so that we will usually apply them without explicitly stating a reference to the following exercise).

Exercise 4.7. Verify the following sentences.

a) 0 is less than 1, i.e.

$$0 <_{\mathbb{N}} 1, \tag{4.164}$$

and 0 is unequal to 1, i.e.

$$0 \neq 1. \tag{4.165}$$

(Hint: Apply (2.291), Corollary 4.21, and Property 2* of a linear ordering.)

b) 1 is less than 2, i.e.

$$1 <_{\mathbb{N}} 2, \tag{4.166}$$

and 1 is unequal to 2, i.e.

$$1 \neq 2. \tag{4.167}$$

c) 0 is less than 2, i.e.

$$0 <_{\mathbb{N}} 2, \tag{4.168}$$

and 0 is unequal to 2, i.e.

$$0 \neq 2. \tag{4.169}$$

(Hint: Use Property 3 and Property 2* of a linear ordering)

The standard linear ordering of a counting set induces a lattice structure of the underlying set C.

Proposition 4.28. *For any counting domain* $(C, s, 0_C)$ *the linearly ordered set* $(C, \leq_C)$ *is a lattice.*

Proof. We let C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain and show that $(C, \leq_C)$ satisfies (3.303). To do this, we let $m, n \in C$ be arbitrary and recall that $\leq_C$ is the total ordering of C which corresponds to the linear ordering $<_C$ (see Theorem 4.19). Consequently, the supremum S and the infimum I of the pair $\{m, n\}$ exist because of Proposition 3.113 and Exercise 3.52, respectively. As m and n are arbitrary, we may therefore conclude that $(C, <_C)$ satisfies (3.303), which ordered pair thus constitutes a lattice. Since C, s and 0_C were also arbitrary, the proposition follows then to be true. □

Corollary 4.29. *The linearly ordered set* $(\mathbb{N}, \leq_{\mathbb{N}})$ *is a lattice.*

We now see that not all subsets of a counting set have a supremum (so that counting sets do not give rise to complete lattices).

Proposition 4.30. *The counting set* C *of any counting domain* $(C, s, 0_C)$ *is not bounded from above, i.e. it is true that*

$$\neg \exists u \, (u \in C \, \land \, \forall n \, (n \in C \Rightarrow n \leq_C u)). \tag{4.170}$$

Proof. Letting C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain, we prove the sentence (4.170) by contradiction, assuming its negation to be true, so that the existential sentence in (4.170) follows to be true with the Double Negation Law. Thus, there exists an element of C, say $\bar{u}$, with

$$\forall n \, (n \in C \Rightarrow n \leq_C \bar{u}).$$

Let us now observe that $\bar{u} \in C$ implies the tautology $\bar{u} <_C s(\bar{u})$ with (4.142). Now, since $\bar{u} \in C$ gives $s(\bar{u}) \in C$ with the definition of a successor function, we obtain with the preceding universal sentence the inequality $s(\bar{u}) \leq_C \bar{u}$, which in turn implies $\neg \bar{u} <_C s(\bar{u})$ with the Negation Formula for $<$, completing the proof by contradiction. Since C, s and 0_C were initially arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Corollary 4.31. *The set of natural numbers does not have an upper bound.*

Proposition 4.32. *It is true for any counting domain* $(C, s, 0_C)$ *that any element of* C *which is greater than or equal to an* $m \in C$ *and less than the successor of* m *is identical to* m*, i.e.*

$$\forall m, n \, (m, n \in C \Rightarrow [(m \leq_C n \, \land \, n <_C s(m)) \Rightarrow n = m]). \tag{4.171}$$

Proof. We let $(C, s, 0_C)$ be an arbitrary counting domain, let m and n be arbitrary in C, and assume then both $m \leq_C n$ and $n <_C s(m)$ to be true. Here, $n <_C s(m)$ implies $\{0_C, \ldots, n\} \subset \{0_C, \ldots, s(m)\}$ with (4.150) and then $\{0_C, \ldots, s(n)\} \subseteq \{0_C, \ldots, s(m)\}$ with (4.102). This finding yields $s(n) \leq_C s(m)$ with (4.141) and consequently $n \leq_C m$ because of (4.162). The conjunction of this and the assumption $m \leq_C n$ then implies the desired equation $n = m$ with the antisymmetry of the partial ordering $\leq_C$. Since m and n are arbitrary, we may therefore conclude that the proposed universal sentence (4.171) is true. □

Exercise 4.8. Show for any counting domain $(C, s, 0_C)$ that any element of C which is greater than an $m \in C$ and less than or equal to the successor of m is identical to that successor, i.e.

$$\forall m, n\,(m, n \in C \Rightarrow [m <_C n \wedge n \leq_C s(m)] \Rightarrow n = s(m)). \tag{4.172}$$

(Hint: Use similar arguments as in the proof of Proposition 4.32.)

Note 4.9. The findings of the preceding proposition and exercise show for any counting domain $(C, s, 0_C)$ that the successor of an $m \in C$ is the 'next greater' element after m.

Corollary 4.33. *The successor m^+ of a natural number m is the next greater natural number after m, in the sense that*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \leq_{\mathbb{N}} n \wedge n <_{\mathbb{N}} m^+] \Rightarrow n = m), \tag{4.173}$$

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m <_{\mathbb{N}} n \wedge n \leq_{\mathbb{N}} m^+] \Rightarrow n = m^+). \tag{4.174}$$

The following theorem provides, retrospectively, the justification for calling each value $u_C(n)$ of the recursively defined function u_C an initial segment of C up to n, as expressed by the notation $\{0_C, \ldots, n\}$.

Theorem 4.34 (Characterization of initial segments). *For any counting domain $(C, s, 0_C)$ it is true that the initial segment of C up to an $n \in C$ contains precisely all elements of C which are less than or equal to n, i.e.*

$$\forall m, n\,(m, n \in C \Rightarrow [m \in \{0_C, \ldots, n\} \Leftrightarrow m \leq_C n]). \tag{4.175}$$

Moreover, it is true for any $n \in C$ that 0_C is the least element and n the greatest element of the initial segment of C up to n, that is,

$$\min \{0_C, \ldots, n\} = 0_C, \tag{4.176}$$

$$\max \{0_C, \ldots, n\} = n. \tag{4.177}$$

Proof. Letting C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain and letting $m, n \in C$ also be arbitrary, we now prove the first part ('$\Rightarrow$') of the equivalence by contradiction, assuming both $m \in \{0_C, \ldots, n\}$ and $\neg m \leq_C n$ to be true. The latter implies $m >_C n$ with the Negation Formula for $\leq$, so that $m = n$ and $m <_C n$ are both false according to the Characterization of comparability (since $<_C$ is a linear ordering). Thus, $m \neq n$ and the assumed $m \in \{0_C, \ldots, n\}$ are both true, so that $s(m) \in \{0_C, \ldots, n\}$ follows to be true with (4.100). Now, since the previously established $m >_C n$ yields $n <_C m$, the disjunction $n <_C m \vee n = m$ is then also true, so that $n \leq_C m$ holds in view of Theorem 3.86b). Consequently, we obtain $\{0_C, \ldots, n\} \subseteq \{0_C, \ldots, m\}$ with (4.141). With this inclusion, the previously established $s(m) \in \{0_C, \ldots, n\}$ implies $s(m) \in \{0_C, \ldots, m\}$ (using the definition of a subset), which contradicts (4.99).

To prove the second part ('$\Leftarrow$') of the proposed equivalence, we assume $m \leq_C n$, which yields $\{0_C, \ldots, m\} \subseteq \{0_C, \ldots, n\}$ with (4.141). Since $m \in \{0_C, \ldots, m\}$ holds according to Proposition 4.13, it follows with the preceding inclusion (with the definition of a subset) that $m \in \{0_C, \ldots, n\}$. This completes the proof of the equivalence, which in turn proves the stated implication. As m and n are arbitrary, we may therefore conclude that the universal sentence (4.175) is true.

Next, we let $n \in C$ be arbitrary and show first that 0_C is a lower bound for $\{0_C, \ldots, n\}$. To do this, we verify sentences

$$\forall m\, (m \in \{0_C, \ldots, n\} \Rightarrow 0_C \leq_C m), \tag{4.178}$$

letting m be arbitrary and assuming $m \in \{0_C, \ldots, n\}$ $[= u_C(n)]$ to be true. Observing now that $u_C(n)$ is by Definition 4.2 of the function $u_C : C \to \mathcal{P}(C)$ and by the Function Criterion a (unique) value of the codomain $\mathcal{P}(C)$ and therefore a subset of C (by definition of a power set), we see that the preceding assumption $m \in u_C(n)$ implies $m \in C$ with the definition of a subset. Consequently, $u_C(m) = \{0_C, \ldots, m\}$ is also a uniquely specified value of the function u_C. It then follows with (4.95) that $0_C \in \{0_C, \ldots, m\}$ holds, which in turn implies the first desired consequent $0_C \leq_C m$ with the Characterization of initial segments. As m is arbitrary, we may therefore conclude that the universal sentence (4.178) holds, so that 0_C is a lower bound for $\{0_C, \ldots, n\}$. Since this lower bound 0_C is an element of that initial segment according to (4.95), we have that 0_C is the minimum element of $\{0_C, \ldots, n\}$, proving (4.176).

Similarly, we may show that n is an upper bound for $\{0_C, \ldots, n\}$, satisfying thusly

$$\forall m\, (m \in \{0_C, \ldots, n\} \Rightarrow m \leq_C n). \tag{4.179}$$

Letting $m \in \{0_C, \ldots, n\}$ be arbitrary, it follows with (4.175) that $m \leq_C n$ holds, which finding proves already the implication in (4.179). As m was arbitrary, we may therefore conclude that (4.179) is true, which means that n is an upper bound for the initial segment $\{0_C, \ldots, n\}$. Moreover, since $n \in \{0_C, \ldots, n\}$ holds with (4.93), the upper bound n is the maximum element of that initial segment, which proves (4.177). Because n, C, s, and 0_C were arbitrary, we may infer from these findings the truth of the stated theorem. □

Corollary 4.35. *The initial segment of* $\mathbb{N}$ *up to a natural number* n *(in other words, the successor of a natural number* n*) consists of all natural numbers that are less than or equal to* n*, that is,*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \in \{0, \ldots, n\} \Leftrightarrow m \leq_{\mathbb{N}} n]), \tag{4.180}$$

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \in n^+ \Leftrightarrow m \leq_{\mathbb{N}} n]). \tag{4.181}$$

Moreover, it is true for any natural number n *that all elements of the initial segment of* $\mathbb{N}$ *up to* n *(in other words, that all elements of the successor of* n*) are between* 0 *and* n*, where* 0 *is the least and* n *the greatest element of that initial segment (successor), that is,*

$$\min\{0, \ldots, n\} = \min n^+ = 0, \tag{4.182}$$

$$\max\{0, \ldots, n\} = \max n^+ = n. \tag{4.183}$$

Proposition 4.36. *The following sentences are true for any counting domain* $(C, s, 0_C)$*.*

a) The beginning 0_C *is a lower bound for* C*, i.e.*

$$\forall n\,(n \in C \Rightarrow 0_C \leq_C n), \tag{4.184}$$

and 0_C *is also the least element of* C*.*

b) For any $n \in C$ *it is false that* n *is less than the beginning* 0_C*, that is,*

$$\forall n\,(n \in C \Rightarrow \neg n <_C 0_C). \tag{4.185}$$

c) There is no element of C *which is less than the initial element, i.e.*

$$\neg\exists n\,(n \in C \wedge n <_C 0_C). \tag{4.186}$$

Proof. Letting C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain and letting n be an arbitrary element of C, the inequality $0_C \leq_C n$ follows with (4.95) and the Characterization of initial segments. As n is arbitrary, it then follows that (4.184) holds, so that 0_C is a lower bound for C by definition. Furthermore, since 0_C is an element of C by definition of a counting domain, the lower bound 0_C for C is the least element of C by definition. Thus, a) is true.

Letting now $n \in C$ be arbitrary, we obtain with a) the inequality $0_C \leq_C n$, which implies $\neg n <_C 0_C$ with the Negation Formula for $<$ (recalling that $<_C$ is a linear ordering). Since n is arbitrary, we may therefore conclude that the universal sentence b) is true.

Finally, we observe that b) implies c) with the Negation Law for existential conjunctions. Since C, s and 0_C were initially arbitrary, we may then conclude that the proposition is true. □

Corollary 4.37. *The following sentences are true for* $(\mathbb{N}, s^+, 0)$*.*

a) 0 *is a lower bound for* $\mathbb{N}$*, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow 0 \leq_{\mathbb{N}} n), \tag{4.187}$$

and 0 *is also the least element of* $\mathbb{N}$*.*

b) For any natural number n *it is false that* n *is less than* 0*, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \neg n <_{\mathbb{N}} 0). \tag{4.188}$$

c) There is no natural number which is less than 0*, that is,*

$$\neg\exists n\,(n \in \mathbb{N} \wedge n <_{\mathbb{N}} 0). \tag{4.189}$$

The particular specification of the set of natural numbers admits the following characterization of its linear ordering, alternatively to the characterization in terms of initial segments.

Lemma 4.38 (Characterization of $<_{\mathbb{N}}$ by $\in_{\mathbb{N}}$). *A natural number* m *is less than a natural number* n *iff* m *is element of* n*, that is,*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m <_{\mathbb{N}} n \Leftrightarrow m \in n]). \tag{4.190}$$

Proof. Let us first rewrite (4.190) equivalently as

$$\forall m\,(m \in \mathbb{N} \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow [m <_{\mathbb{N}} n \Leftrightarrow m \in n])) \tag{4.191}$$

by applying (1.90). We now let m be arbitrary in $\mathbb{N}$ and carry out a proof by mathematical induction with respect to n. Concerning the base case $(n = 0)$, we prove $m <_{\mathbb{N}} 0 \Leftrightarrow m \in 0$, which is by definition of the zero 0 equivalent to

$$m <_{\mathbb{N}} 0 \Leftrightarrow m \in \emptyset.$$

Here, the first part $m <_{\mathbb{N}} 0 \Rightarrow m \in \emptyset$ of the equivalence is true since $m <_{\mathbb{N}} 0$ is false due to (4.188); the second part $m \in \emptyset \Rightarrow m <_{\mathbb{N}} 0$ of the equivalence is also true because $m \in \emptyset$ is false by definition of the empty set. Concerning the induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption $m <_{\mathbb{N}} n \Leftrightarrow m \in n$, and show that this implies

$$m <_{\mathbb{N}} n^+ \Leftrightarrow m \in n^+. \tag{4.192}$$

To prove the first part ('$\Rightarrow$') of this equivalence, we assume $m <_{\mathbb{N}} n^+$, which implies $m^+ \leq_{\mathbb{N}} n^+$ with (4.157). The latter further implies $m \leq_{\mathbb{N}} n$ with (4.159), which inequality then gives the desired $m \in n^+$ with (4.181).

To prove the second part ('$\Leftarrow$') of the equivalence (4.192), we now assume $m \in n^+$ to be true, which implies $m \leq_{\mathbb{N}} n$ again with (4.181). Let us now recall that $n <_{\mathbb{N}} n^+$ holds due to (4.153). Then, the conjunction of $m \leq_{\mathbb{N}} n$ and $n <_{\mathbb{N}} n^+$ implies $m <_{\mathbb{N}} n^+$ with the Transitivity Formula for $\leq$ and $<$, which completes the proof of the equivalence (note that we did not have to use the induction assumption). As n is arbitrary, we therefore conclude that the induction step is true, so that the proof by mathematical induction of the universal sentence with respect to n in (4.191) is complete. Since m was also arbitrary, it then follows that the lemma (4.190) holds. □

Theorem 4.39. *The binary relation of belonging* $\in_{\mathbb{N}}$ *is a linear ordering of* $\mathbb{N}$.

Proof. We already established $\in_{\mathbb{N}}$ as an irreflexive partial ordering of $\mathbb{N}$ (see Corollary 4.5). It therefore remains to show that $\in_{\mathbb{N}}$ is connex, i.e. that $\in_{\mathbb{N}}$ satisfies

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \in n \,\vee\, n \in m \,\vee\, m = n]). \tag{4.193}$$

For this purpose, we let $m, n \in \mathbb{N}$ be arbitrary and observe that the linear ordering $<_{\mathbb{N}}$ is connex, so that

$$m <_{\mathbb{N}} n \,\vee\, n <_{\mathbb{N}} m \,\vee\, m = n \tag{4.194}$$

holds. Now, in light of (4.190), we see that $m <_{\mathbb{N}} n$ is equivalent to $m \in n$ and that $n <_{\mathbb{N}} m$ is equivalent to $n \in m$. Therefore, the true multiple disjunction (4.194) implies the truth of the equivalent multiple disjunction in (4.193). As m and n are arbitrary, we may therefore conclude that (4.193) is true, so that the irreflexive partial ordering $\in_{\mathbb{N}}$ is indeed connex, and thus by definition a linear ordering of $\mathbb{N}$. □

We already explored the presence of extremal elements of a counting set and of an initial segment. Our next task is to extend these investigations to more general subsets of a counting set.

Proposition 4.40. *The following sentences are true for any counting domain* $(C, s, 0_C)$.

a) Every nonempty subset of the initial segment of C *up to an* $n \in C$ *has a greatest element, that is,*

$$\forall n\,(n \in C \Rightarrow \forall A\,([A \subseteq \{0_C, \ldots, n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \max A))). \tag{4.195}$$

b) Any nonempty and bounded-from-above subset of C *has a greatest element, that is,*

$$\begin{aligned}&\forall A\,([A \subseteq C \,\wedge\, A \neq \emptyset \,\wedge\, \exists u\,(u \in C \,\wedge\, \forall k\,(k \in A \Rightarrow k \leq_C u)] \\ &\quad \Rightarrow \exists m\,(m = \max A))).\end{aligned} \tag{4.196}$$

Proof. We let C, s and 0_C be arbitrary and assume $(C, s, 0_C)$ to be a counting domain. Concerning a), we carry out a proof by mathematical induction. Regarding the base case ($n = 0_C$), we prove

$$\forall A\,([A \subseteq \{0_C, \ldots, 0_C\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \max A)). \tag{4.197}$$

Letting A be arbitrary and assuming both $A \subseteq \{0_C, \ldots, 0_C\}$ and $A \neq \emptyset$ to be true, we obtain the equations

$$\{0_C, \ldots, 0_C\} = u_C(0_C) = \{0_C\}$$

by using the definition of an initial segment, so that the assumed $A \subseteq \{0_C, \ldots, 0_C\}$ gives $A \subseteq \{0_C\}$ via substitution. The disjunction of the latter inclusion and the assumed $A \neq \emptyset$ further implies $A = \{0_C\}$ with (2.186). Since $\max\{0_C\} = 0_C$ holds according to Corollary 3.96, it follows with $A = \{0_C\}$ that $\max A = 0_C$, which evidently proves the existential sentence in (4.197), and thus the implication in (4.197). Because A is arbitrary, we may therefore conclude that the universal sentence (4.197) holds, completing the proof of the base case, holds.

Regarding the induction step, we let $n \in C$ be arbitrary, make the induction assumption

$$\forall A\,([A \subseteq \{0_C, \ldots, n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \max A)), \tag{4.198}$$

and prove

$$\forall A\,([A \subseteq \{0_C, \ldots, s(n)\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \max A)). \tag{4.199}$$

To do this, we let A be arbitrary and prove the implication by cases. In the first case, we assume $A \subseteq \{0_C, \ldots, s(n)\}$ and $A \neq \emptyset$ as well as $s(n) \in A$, and we prove the consequent (i.e. the existential sentence) in (4.199) by demonstrating that $s(n) = \max A$ holds. For this purpose, we first verify that $s(n)$ is an upper bound for A, that is,

$$\forall m\,(m \in A \Rightarrow m \leq_C s(n)). \tag{4.200}$$

Letting m be arbitrary in A, it follows with the assumed inclusion $A \subseteq \{0_C, \ldots, s(n)\}$ and the definition of a subset that $m \in \{0_C, \ldots, s(n)\}$. Since $s(n) = \max\{0_C, \ldots, s(n)\}$ holds with (4.177) and the definition of an initial segment, we have in particular that $m \leq_C s(n)$, because the maximum element $s(n)$ is an upper bound for $\{0_C, \ldots, s(n)\}$. As m is arbitrary, we may therefore conclude that (4.200) is true, which then gives together with the case assumption $s(n) \in A$ with the definition of a greatest element the desired $s(n) = \max A$.

In the second case, we assume the conjunction of $A \subseteq \{0_C, \ldots, s(n)\}$, $A \neq \emptyset$ and $s(n) \notin A$. Here, the conjunction of the first and the last part implies $A \subseteq \{0_C, \ldots, s(n)\} \setminus \{s(n)\}$ with (2.188), and therefore $A \subseteq \{0_C, \ldots, n\}$ with (4.134). The conjunction of this and the assumption $A \neq \emptyset$ then implies $\exists m\,(m = \max A)$ with the induction assumption (4.198), which completes the proof of the implication in (4.199) by cases. Since A is arbitrary, we may therefore conclude that (4.199) is true; as n was also arbitrary, we may then further conclude that the induction step holds, which completes the proof of (4.195) via mathematical induction.

Concerning b), we let A be arbitrary and prove the implication directly, assuming that A is a nonempty subset of C and that there exists an upper bound for A in C, say $\bar{u}$. Let us first prove that $A \subseteq \{0_C, \ldots, \bar{u}\}$ holds, i.e. (using the definition of a subset)

$$\forall k\,(k \in A \Rightarrow k \in \{0_C, \ldots, \bar{u}\}), \tag{4.201}$$

which will – together with the assumption $A \neq \emptyset$ – imply the desired consequent. We let k be arbitrary and prove the implication in (4.201) directly, assuming that $k \in A$ holds, which implies on the one hand $k \in C$ with the initial assumption $A \subseteq C$ (by definition of a subset). On the other hand, $k \in A$ implies $k \leq_C \bar{u}$ with the assumption that $\bar{u}$ is an upper bound for A. It then follows with the Characterization of initial segments that $k \in \{0_C, \ldots, \bar{u}\}$, which proves the implication in (4.201). Since k is arbitrary, we therefore conclude that the universal sentence (4.201) holds, which means $A \subseteq \{0_C, \ldots, \bar{u}\}$. Then, the conjunction of this and the initial assumption $A \neq \emptyset$ implies with (4.195) the existential sentence $\exists m\,(m = \max A)$, which in turn proves the implication in (4.196). Since A was arbitrary, we may then conclude that (4.196) holds.

As C, s and 0_C were initially arbitrary in the proofs of a) and b), it finally follows that the proposition is true. □

Corollary 4.41. *The following sentences are true for the counting domain* $(\mathbb{N}, s^+, 0)$.

a) Every nonempty subset of the initial segment of $\mathbb{N}$ *up to a natural number* n *has a greatest element, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \forall A\,([A \subseteq \{0, \ldots, n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \max A))). \tag{4.202}$$

b) Any nonempty and bounded-from-above subset of $\mathbb{N}$ *has a greatest element, that is,*

$$\begin{aligned}&\forall A\,([A \subseteq \mathbb{N} \,\wedge\, A \neq \emptyset \,\wedge\, \exists u\,(u \in \mathbb{N} \,\wedge\, \forall k\,(k \in A \Rightarrow k \leq_{\mathbb{N}} u)]\\ &\quad \Rightarrow \exists m\,(m = \max A))).\end{aligned} \tag{4.203}$$

Since every counting set has a least element (viz. its beginning), the conditions for the existence of least elements for subsets of a counting set are less restrictive than those for the existence of greatest elements.

Proposition 4.42. *The following sentences are true for any counting domain* $(C, s, 0_C)$.

a) Every nonempty subset of the initial segment of C *up to an* $n \in C$ *has a least element, that is,*

$$\forall n\,(n \in C \Rightarrow \forall A\,([A \subseteq \{0_C, \ldots, n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \min A))). \tag{4.204}$$

b) Any nonempty subset of C *has a least element, that is,*

$$\forall A\,([A \subseteq C \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \min A))). \tag{4.205}$$

Proof. We let C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain. Concerning a), we carry out a proof by mathematical induction. Regarding the base case ($n = 0_C$), we let A be an arbitrary nonempty subset of $\{0_C, \ldots, 0_C\} = u_C(0_C) = \{0_C\}$. Then, the conjunction of $A \subseteq \{0_C\}$ and $A \neq \emptyset$ implies $A = \{0_C\}$ with (2.186). As $\min\{0_C\} = 0_C$ is true due to Corollary 3.96, we have that $\min A = 0_C$, which proves the existential sentence and thus the inner implication in (4.204) for $n = 0_C$. As A is arbitrary, we therefore conclude that the base case holds. Regarding the induction step, we let n be arbitrary in C, make the induction assumption

$$\forall A\,([A \subseteq \{0_C, \ldots, n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \min A)), \tag{4.206}$$

and prove

$$\forall A\,([A \subseteq \{0_C, \ldots, s(n)\} \wedge A \neq \emptyset] \Rightarrow \exists m\,(m = \min A)). \tag{4.207}$$

For this purpose, we let A be arbitrary and prove the implication by cases, considering the two exhaustive cases $A \cap \{0_C, \ldots, n\} = \emptyset$ and $A \cap \{0_C, \ldots, n\} \neq \emptyset$. In the first case, we assume

$$A \subseteq \{0_C, \ldots, s(n)\} \wedge A \neq \emptyset \wedge A \cap \{0_C, \ldots, n\} = \emptyset$$

and show first that this implies $A \subseteq \{s(n)\}$, i.e. (using the definition of a subset)

$$\forall y\,(y \in A \Rightarrow y \in \{s(n)\}). \tag{4.208}$$

To do this, we let $\bar{y}$ be arbitrary and assume $\bar{y} \in A$, which implies with the assumption $A \subseteq \{0_C, \ldots, s(n)\}$ (and the definition of a subset) that $\bar{y} \in \{0_C, \ldots, s(n)\}$, and therefore with (4.86) $\bar{y} \in \{0_C, \ldots, n\} \cup \{s(n)\}$, thus (by definition of the union of two sets)

$$\bar{y} \in \{0_C, \ldots, n\} \vee \bar{y} \in \{s(n)\}. \tag{4.209}$$

Let us now observe that the case assumption $A \cap \{0_C, \ldots, n\} = \emptyset$ means (by definition of the empty set)

$$\forall y\,(y \notin A \cap \{0_C, \ldots, n\}),$$

so that we obtain in particular $\neg \bar{y} \in A \cap \{0_C, \ldots, n\}$ and therefore (applying the definition of the intersection of two sets and De Morgan's Law for sets (2.259))

$$\bar{y} \notin A \vee \bar{y} \notin \{0_C, \ldots, n\}.$$

Now, as $\bar{y} \in A$ is true by assumption, $\bar{y} \notin A$ is false and consequently the second part $\bar{y} \notin \{0_C, \ldots, n\}$ of the preceding disjunction is true; thus, the first part of the disjunction (4.209) is false, so that the second part $\bar{y} \in \{s(n)\}$ of that true disjunction is true. Since $\bar{y}$ is arbitrary, we may therefore conclude that the universal sentence (4.208) holds, which means that $A \subseteq \{s(n)\}$ is indeed true. Now, the conjunction of this inclusion and the assumed $A \neq \emptyset$ implies $A = \{s(n)\}$ with (2.186). It then follows with Corollary 3.96 that $s(n)$ is the least element of A, which proves the existential sentence in (4.207).

We now prove the implication in (4.207) for the second case, assuming accordingly

$$A \subseteq \{0_C, \ldots, s(n)\} \wedge A \neq \emptyset \wedge A \cap \{0_C, \ldots, n\} \neq \emptyset.$$

Applying (2.74), we have

$$(\emptyset \neq)\ A \cap \{0_C, \ldots, n\} \subseteq \{0_C, \ldots, n\},$$

which implies with the induction assumption (4.206) that the least element $\bar{m}$ of $A \cap \{0_C, \ldots, n\}$ exists. By definition of a least element, we thus have that $\bar{m}$ is element of that intersection, so that $\bar{m} \in A$ and $\bar{m} \in \{0_C, \ldots, n\}$ are both true according to the definition of the intersection of two sets. Let us now verify that $\bar{m}$ is also a lower bound for A, that is,

$$\forall y\, (y \in A \Rightarrow \bar{m} \leq_C y). \tag{4.210}$$

Letting $\bar{y}$ be arbitrary and assuming $\bar{y} \in A$ to be true, we may apply the same arguments as in the first case to infer from this in view of the assumption $A \subseteq \{0_C, \ldots, s(n)\}$ the truth of the disjunction (4.209) for the current constant $\bar{y}$. We may now use this true disjunction to prove the sentence $\bar{m} \leq_C \bar{y}$. Firstly, if $\bar{y} \in \{0_C, \ldots, n\}$ is true, then this implies together with $\bar{y} \in A$ (with the definition of the intersection of two sets) that $\bar{y} \in A \cap \{0_C, \ldots, n\}$ holds, which gives $\bar{m} \leq_C \bar{y}$ since $\bar{m}$ is the least element of and thus a lower bound for $A \cap \{0_C, \ldots, n\}$. Secondly, if $\bar{y} \in \{s(n)\}$ is true, which implies $\bar{y} = s(n)$ with (2.169), we may establish the inequalities

$$\bar{m} \leq_C n <_C \bar{y} \quad [= s(n)]. \tag{4.211}$$

Here, the first inequality results from the fact that $\bar{m} \in A \cap \{0_C, \ldots, n\}$ implies in particular $\bar{m} \in \{0_C, \ldots, n\}$ (by definition of the intersection of two sets) and then $\bar{m} \leq_C n$ with the Characterization of initial segments. The second inequality is true since $n <_C s(n)$ holds according to Theorem 4.19b). The inequalities (4.211) further imply $\bar{m} <_C \bar{y}$ with the Transitivity Formula for $\leq$ and $<$, and the disjunction $\bar{m} <_C \bar{y} \vee \bar{m} = \bar{y}$ is then also true, so that we obtain $\bar{m} \leq_C \bar{y}$ with (3.253). Thus, the proof by cases of the preceding inequality is complete, which in turn proves the implication in (4.210). Since $\bar{y}$ was arbitrary, we may therefore conclude that the universal sentence (4.210) holds, which means that $\bar{m}$ is indeed a lower bound for A. We already showed that $\bar{m}$ is an element of A, so that the lower bound $\bar{m}$ is the least element of A. Thus, the existential sentence in (4.207) is true also in the second case.

As A was arbitrary, we may therefore conclude that (4.207) is true, and since n was also arbitrary, we may now further conclude that the induction step holds. Thus, the proof by mathematical induction of (4.204) is complete.

Concerning b), we let A be arbitrary such that $A \subseteq C$ and $A \neq \emptyset$ both hold. The latter implies with (2.42) that there is an element in A, say $\bar{n}$.

Applying the definition of a subset to the assumption $A \subseteq C$, we therefore obtain $\bar{n} \in C$ and then also $\bar{n} \in \{0_C, \ldots, \bar{n}\}$ with Proposition 4.13. The conjunction of this and the previously established $\bar{n} \in A$ further implies $\bar{n} \in A \cap \{0_C, \ldots, \bar{n}\}$ by definition of the intersection of two sets. Thus, the set $A \cap \{0_C, \ldots, \bar{n}\}$ is evidently nonempty and furthermore the inclusion $A \cap \{0_C, \ldots, \bar{n}\} \subseteq \{0_C, \ldots, \bar{n}\}$ holds due to (2.74). It then follows with a) from these findings that the least element $\bar{m}$ of $A \cap \{0_C, \ldots, \bar{n}\}$ exists. Let us observe here that the least element $\bar{m}$ is by definition an element of the preceding intersection and is therefore both in A and in $\{0_C, \ldots, \bar{n}\}$. To show that $\bar{m}$ is also the least element of A, it therefore suffices (in view of $\bar{m} \in A$) to show that $\bar{m}$ is a lower bound for A, i.e.

$$\forall y \, (y \in A \Rightarrow \bar{m} \leq_C y). \tag{4.212}$$

For this purpose, we let y be arbitrary and assume $y \in A$ to be true. This implies with the assumption $A \subseteq C$ (and the definition of a subset) that $y \in C$ holds. Since $\leq_C$ is total, the disjunction $y \leq_C \bar{n} \vee \bar{n} \leq_C y$ is true, which we now use to prove the sentence $\bar{m} \leq_C y$ by cases. On the one hand, if $y \leq_C \bar{n}$ is true, then $y \in \{0, \ldots, \bar{n}\}$ holds due to the Characterization of initial segments. The conjunction of this and $y \in A$ then implies $y \in A \cap \{0, \ldots, \bar{n}\}$ (by definition of the intersection of two sets), and therefore $\bar{m} \leq_C y$ (since $\bar{m}$ is the least element of $A \cap \{0, \ldots, \bar{n}\}$). On the other hand, if $\bar{n} \leq_C y$ is true, then we may combine this inequality with the inequality $\bar{m} \leq_C \bar{n}$, which we obtain from the previous observation $\bar{m} \in \{0_C, \ldots, \bar{n}\}$ with the Characterization of initial segments, to form $\bar{m} \leq_C \bar{n} \leq_C y$. This conjunction implies now the desired $\bar{m} \leq_C y$ with the transitivity of $\leq_C$, so that the proof of this inequality by cases is complete. Since y is arbitrary, we may therefore conclude that (4.212) is true, which shows that $\bar{m}$ is indeed a lower bound for A. Since $\bar{m}$ is in A, the lower bound $\bar{m}$ is the least element of A. Thus, the existential sentence in (4.205) is evidently true, and since A was arbitrary, we may infer from this the truth of the universal sentence (4.205).

As C, s and 0_C were arbitrary in the proofs of a) and b), we may finally conclude that the proposition holds, as claimed. □

Corollary 4.43. *For any counting domain $(C, s, 0_C)$ it is true that $(C, \leq_C)$ is a well ordered set.*

Proof. Letting $(C, s, 0_C)$ be an arbitrary counting domain, we have that $(C, \leq_C)$ is a totally ordered set. Together with Proposition 4.42b), this means that $(C, \leq_C)$ is by definition a well ordered set. This is then true for any counting domain. □

The preceding proposition and corollary are immediately applicable, respectively, to the counting domain and to the lattice based on the set of natural numbers.

Corollary 4.44. *The following sentences are true for the counting domain* $(\mathbb{N}, s^+, 0)$.

a) Every nonempty subset of the initial segment of $\mathbb{N}$ *up to a natural number* n *has a least element, that is,*

$$\forall n \, (n \in \mathbb{N} \Rightarrow \forall A \, ([A \subseteq \{0, \ldots, n\} \, \wedge \, A \neq \emptyset] \Rightarrow \exists m \, (m = \min A))). \tag{4.213}$$

b) Any nonempty subset of $\mathbb{N}$ *has a least element, that is,*

$$\forall A \, ([A \subseteq \mathbb{N} \, \wedge \, A \neq \emptyset] \Rightarrow \exists m \, (m = \min A))). \tag{4.214}$$

Corollary 4.45. *The lattice* $(\mathbb{N}, \leq_{\mathbb{N}})$ *is well-ordered.*

4.4. The Counting Domain $(\mathbb{N}_+, s^+ \upharpoonright \mathbb{N}_+, 1)$ and the Linearly Ordered Set $(\mathbb{N}_+, <_{\mathbb{N}_+})$

Given any counting domain, we may construct a new one by removing any initial segment from the given counting set, by letting the new beginning be the successor of the greatest element from the removed initial segment, and by restricting the given successor function to the new counting set.

Theorem 4.46 (Generation of counting domains from restricted counting sets). *For any counting domain $(C, s, 0_C)$ and any $m \in C$ the ordered triple*

$$(C \setminus \{0_C, \ldots, m\}, s \upharpoonright C \setminus \{0_C, \ldots, m\}, s(m)) \tag{4.215}$$

is also a counting domain.

Proof. Letting $(C, s, 0_C)$ be an arbitrary counting domain and m an arbitrary element of C we now verify that $(\bar{C}, s \upharpoonright \bar{C}, s(m))$ with $\bar{C} = C \setminus \{0_C, \ldots, m\}$ satisfies the Properties 1 – 3 of a counting domain.

Regarding Property 1, we demonstrate the truth of

$$\forall n \, (n \in \bar{C} \Rightarrow s \upharpoonright \bar{C}(n) \neq s(m)). \tag{4.216}$$

For this purpose, we let n be arbitrary in $\bar{C} = C \setminus \{0_C, \ldots, m\}$, so that $n \in C$ and $\neg n \in \{0_C, \ldots, m\}$ holds by definition of a set difference. Since $n \in \{0_C, \ldots, m\}$ is equivalent to $n \leq_C m$ in view of the Characterization of initial segments, it follows with the Substitution Rule for negations from the preceding negation that $\neg n \leq_C m$ is true, which inequality in turn implies $m <_C n$ with the Negation Formula for $\leq$. We therefore obtain $s(m) \leq_C n$ by applying (4.156), and $n <_C s(n)$ also holds according to (4.142). Now, the conjunction of $s(m) \leq_C n$ and $n <_C s(n)$ implies $s(m) <_C s(n)$ with the Transitivity Formula for $\leq$ and $<$, and therefore $s(m) \neq s(n)$ because of the Characterization of comparability in connection with the linear ordering $<_C$. Furthermore, since $\bar{C} = C \setminus \{0_C, \ldots, m\}$ implies $\bar{C} \subseteq C$ with (2.125), it follows from $n \in \bar{C}$ in connection with the definition of the successor function that the equation $s \upharpoonright \bar{C}(n) = s(n)$ holds because of Corollary 3.165. With this, the previously established inequality $s(m) \neq s(n)$ yields $s(m) \neq s \upharpoonright \bar{C}(n)$ via substitution, proving the implication in (4.216). As n was arbitrary, we may therefore conclude that (4.216) is true, which means that $(\bar{C}, s \upharpoonright \bar{C}, s(m))$ satisfies Property 1 of a counting domain.

Regarding Property 2, we prove accordingly

$$\forall m, n \, ([m, n \in \bar{C} \, \wedge \, s \upharpoonright \bar{C}(m) = s \upharpoonright \bar{C}(n)] \Rightarrow m = n). \tag{4.217}$$

To do this, we let m and n be arbitrary in $\bar{C}$ such that $s \restriction \bar{C}(m) = s \restriction \bar{C}(n)$ holds. Since the equations $s \restriction \bar{C}(m) = s(m)$ and $s \restriction \bar{C}(n) = s(n)$ are true (again by Corollary 3.165), we obtain after substitution $s(m) = s(n)$. As the successor function s of the counting domain $(C, s, 0_C)$ satisfies (4.2), it follows from the preceding equation that $m = n$. Because m and n are arbitrary, we may then conclude that $(\bar{C}, s \restriction \bar{C}, s(m))$ satisfies indeed (4.217), and thus Property 2.

Regarding Property 3, we verify

$$\forall M\, ([M \subseteq \bar{C} \,\wedge\, s(m) \in M \,\wedge\, \forall n\, (n \in M \Rightarrow s \restriction \bar{C}(n) \in M)] \Rightarrow M = \bar{C}). \tag{4.218}$$

We let M be an arbitrary subset of $\bar{C}$ such that $s(m) \in M$ and the universal sentence

$$\forall n\, (n \in M \Rightarrow s \restriction \bar{C}(n) \in M) \tag{4.219}$$

hold. The former assumption means $M \subseteq C \setminus \{0_C, \ldots, m\}$ (by definition of $\bar{C}$), which implies with (2.251)

$$M \cup \{0_C, \ldots, m\} \;\subseteq\; (C \setminus \{0_C, \ldots, m\}) \cup \{0_C, \ldots, m\}. \tag{4.220}$$

As the initial segment $\{0_C, \ldots, m\}$ is a subset of C, we may apply (2.263) to obtain the equation

$$(C \setminus \{0_C, \ldots, m\}) \cup \{0_C, \ldots, m\} = C,$$

so that (4.220) becomes

$$M \cup \{0_C, \ldots, m\} \subseteq C. \tag{4.221}$$

Then,

$$0_C \in M \cup \{0_C, \ldots, m\} \tag{4.222}$$

holds by definition of the union of a pair. We now verify

$$\forall n\, (n \in M \cup \{0_C, \ldots, m\} \Rightarrow s(n) \in M \cup \{0_C, \ldots, m\}). \tag{4.223}$$

For this purpose, we let n be arbitrary in $M \cup \{0_C, \ldots, m\}$, so that the disjunction

$$n \in M \,\vee\, n \in \{0_C, \ldots, m\}$$

follows to be true (by definition of the union of two sets), which we now use to prove the sentence $s(n) \in M \cup \{0_C, \ldots, m\}$ by cases.

On the one hand, if $n \in M$ is true, then $s \restriction \bar{C}(n) \in M$ also holds due to (4.219), and therefore $s(n) \in M$ with $s \restriction \bar{C}(n) = s(n)$ (applying Corollary 3.165). Then, $s(n) \in M$ implies that the disjunction

$$s(n) \in M \,\vee\, s(n) \in \{0_C, \ldots, m\} \tag{4.224}$$

is true (no matter if $s(n) \in \{0_C, \ldots, m\}$ is true or false), and this disjunction gives (by definition of the union of two sets) the desired consequent $s(n) \in M \cup \{0_C, \ldots, m\}$ of the implication in (4.223).

On the other hand, if $n \in \{0_C, \ldots, m\}$ is true, then it follows with the Characterization of initial segments that $n \leq_C m$ holds, which yields $n <_C m \vee n = m$ since the induced linear ordering $<_C$ satisfies (3.253). We now carry out a proof of the sentence (4.224) by cases based on the preceding true disjunction. In case $n <_C m$ holds, we obtain the inequality $s(n) \leq_C m$ with (4.156), and therefore $s(n) \in \{0_C, \ldots, m\}$ with the Characterization of initial segments, so that the disjunction (4.224) holds (irrespective of the truth value of $s(n) \in M$). In the other case that $n = m$ is true, we obtain $s(n) = s(m)$ because s – being a function – satisfies Corollary 3.150. With the latter equation, the initial assumption $s(m) \in M$ gives $s(n) \in M$ via substitution, so that the disjunction (4.224) is again true. Thus, the proof of this disjunction by cases is complete, so that $s(n) \in M \cup \{0_C, \ldots, m\}$ follows to be true. This completes the proof by cases of this sentence, and this completes also the proof of the implication in (4.223). Since n is arbitrary, we may therefore conclude that the universal sentence (4.223) is true. Now, the conjunction of (4.221), (4.222) and (4.223) implies

$$M \cup \{0_C, \ldots, m\} = C \tag{4.225}$$

with (4.3), using the fact that $(C, s, 0_C)$ satisfies Property 3 of a counting domain. Then, as the assumption $M \subseteq C \setminus \{0_C, \ldots, m\}$ implies $M \cap \{0_C, \ldots, m\} = \emptyset$ with (2.117), we may apply (2.262) to obtain from (4.225) the equation $M = C \setminus \{0_C, \ldots, m\}$, which gives $M = \bar{C}$. Because M was arbitrary, we may therefore conclude that the universal sentence (4.218) is true, so that $(\bar{C}, s \upharpoonright \bar{C}, s(m))$ satisfies also Property 3 of a counting domain. Since m, C, s and 0_C were initially arbitrary, we may finally conclude that the stated theorem is indeed true. □

The preceding theorem immediately yields the counting domain based on the set of positive natural numbers.

Corollary 4.47. *The ordered triple*

$$(\mathbb{N}_+, s^+ \upharpoonright \mathbb{N}_+, 1) \tag{4.226}$$

constitutes a counting domain.

Proof. Since $\mathbb{N}_+ = \mathbb{N} \setminus \{0\}$ holds by definition of the set of positive natural numbers, where $\{0\}$ is by definition the initial segment of $\mathbb{N}$ up to 0, the corollary holds in view of $s^+(0) = 0^+ = 1$ and Theorem 4.46. □

Note 4.10. In the proof of Theorem 4.46, we used the fact that $s \upharpoonright \bar{C}(n) = s(n)$ holds for an arbitrary $n \in \bar{C}$, where s is the successor function with domain C. In the particular instance of $C = \mathbb{N}$, we have the successor function s^+, whose restriction to $\bar{C} = \mathbb{N}_+$ then yields, according to the preceding equation, the values

$$s^+ \upharpoonright \mathbb{N}_+(n) = s^+(n) = n^+. \tag{4.227}$$

Thus, we may use the notation n^+ both for the successor of a natural number n and for the successor of a positive natural number n.

Exercise 4.9. Verify that the ordered triple

$$(\mathbb{N}_+ \setminus \{1\}, s^+ \upharpoonright \mathbb{N}_+ \setminus \{1\}, 2) \tag{4.228}$$

is also a counting domain.

In view of the preceding notation for the successor of an element of the counting set $\mathbb{N}_+$, the following three results immediately follow by applying Theorem 4.1, Proposition 4.2 and 4.3 to the counting domain $(\mathbb{N}_+, s^+ \upharpoonright \mathbb{N}_+, 1)$.

Corollary 4.48. *A positive natural number is* 1 *or the successor of another positive natural number, that is,*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow [n = 1 \lor \exists m\,(m \in \mathbb{N}_+ \land m \neq n \land m^+ = n)]). \tag{4.229}$$

Corollary 4.49. *The successor function of the particular counting domain* $(\mathbb{N}_+, s^+ \upharpoonright \mathbb{N}_+, 1)$ *is a bijection from* $\mathbb{N}_+$ *to* $\mathbb{N}_+ \setminus \{1\}$*, that is,*

$$s^+ \upharpoonright \mathbb{N}_+ : \mathbb{N}_+ \rightleftarrows \mathbb{N}_+ \setminus \{1\}. \tag{4.230}$$

Corollary 4.50. *Any positive natural number is different from its successor, that is,*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow n^+ \neq n). \tag{4.231}$$

Because we established the proof method of mathematical induction for general counting domains, we now see that this method may not only be applied with respect to the counting set $\mathbb{N}$, but also to with respect to $\mathbb{N}_+$.

Method 4.4 (Proof by mathematical induction (for $\mathbb{N}_+$)). To prove that a given formula $\varphi(n)$ holds for all positive natural numbers, we may show that the base case

$$\varphi(1) \tag{4.232}$$

and the induction step

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow [\varphi(n) \Rightarrow \varphi(n^+)]) \tag{4.233}$$

are true.

Exercise 4.10. Establish a proof method based on mathematical induction for $\mathbb{N}_+ \setminus \{1\}$.

Next, we specialize Method 4.2 to $\mathbb{N}_+$.

Method 4.5 (Definition by recursion (for $\mathbb{N}_+$)). To define for an arbitrary set A, an arbitrary function $f : \mathbb{N}_+ \times A \to A$ and an arbitrary $a \in A$ the function $u : \mathbb{N}_+ \to A$ which satisfies (4.55) with respect to the particular counting domain $(\mathbb{N}_+, s^+ \restriction \mathbb{N}_+, 1)$, we will write

$$(1) \quad u_1 = a, \tag{4.234}$$

$$(2) \quad u_{n^+} = f(n, u_n) \quad \text{for any } n \in \mathbb{N}_+. \tag{4.235}$$

We now characterize initial segments of the counting set $\mathbb{N}_+$ according to the previous findings for a generic counting set.

Notation 4.4. In the particular instance of the counting domain $(\mathbb{N}_+, s^+ \restriction \mathbb{N}_+, 1)$, we obtain for the *initial segment of* $\mathbb{N}_+$ (up to n)

$$(1) \quad u_{\mathbb{N}_+}(1) = \{1\}, \tag{4.236}$$

$$(2) \quad u_{\mathbb{N}_+}(n^+) = u_{\mathbb{N}_+}(n) \cup \{n^+\} \quad \text{for any } n \in \mathbb{N}_+, \tag{4.237}$$

and we write for any $n \in \mathbb{N}_+$ (including $n = 1$)

$$\{1, \ldots, n\} = u_{\mathbb{N}_+}(n). \tag{4.238}$$

Furthermore, we write in case of $n = 0$ ($\notin \mathbb{N}_+$) also

$$\{1, \ldots, n\} = \{1, \ldots, 0\} = \emptyset. \tag{4.239}$$

Exercise 4.11. Show that the initial segment of $\mathbb{N}_+$ up to any natural number n is included both in the set of natural numbers and in the set of positive natural numbers, that is,

$$\forall n \, (n \in \mathbb{N} \Rightarrow [\{1, \ldots, n\} \subseteq \mathbb{N}_+ \, \wedge \, \{1, \ldots, n\} \subseteq \mathbb{N}]). \tag{4.240}$$

(Hint: Apply Method 1.9 based on (2.310).)

Proposition 4.51. *The initial segment of* $\mathbb{N}_+$ *up to the successor of a natural number* n *is identical with the union of the initial segment of* $\mathbb{N}_+$ *up to* n *and the singleton formed by that successor, that is,*

$$\forall n \, (n \in \mathbb{N} \Rightarrow \{1, \ldots, n^+\} = \{1, \ldots, n\} \cup \{n^+\}). \tag{4.241}$$

Proof. We let $n \in \mathbb{N}$ be arbitrary, so that the disjunction $n = 0 \lor n \in \mathbb{N}_+$ follows to be true with (2.310), which we now use to prove the stated equation by cases.

In case of $n = 0$, we obtain the equations

$$\begin{aligned}
\{1, \ldots, n^+\} &= \{1, \ldots, 0^+\} \\
&= \{1, \ldots, 1\} \\
&= \{1\} \\
&= \emptyset \cup \{1\} \\
&= \{1, \ldots, 0\} \cup \{0^+\} \\
&= \{1, \ldots, n\} \cup \{n^+\}
\end{aligned}$$

by applying substitution, (2.291), (4.236) together with (4.238), (2.216), (4.239) together with (2.291), and finally again substitution based on the case assumption. In the other case of $n \in \mathbb{N}_+$, we obtain the desired equation immediately with (4.237) and (4.238). Thus, the proof by cases is complete, and since n was initially arbitrary, we may therefore conclude that the universal sentence (4.241) holds, as claimed. □

Exercise 4.12. Show that the initial segment of $\mathbb{N}_+$ up to 2 is identical with the pair formed by 1 and 2, that is,

$$\{1, \ldots, 2\} = \{1, 2\}. \tag{4.242}$$

(Hint: Use (2.292), (4.241), Notation 4.4 and (2.226).)

Exercise 4.13. Verify the following sentence.

$$\forall n\, (n \in \mathbb{N} \Rightarrow \{1, \ldots, n\} \cap \{n^+\} = \emptyset). \tag{4.243}$$

(Hint: Apply Method 1.9 in connection with (2.310), and use (4.239), (2.62), as well as (4.133).)

We now establish two useful relationships between initial segments of $\mathbb{N}$ and of $\mathbb{N}_+$.

Proposition 4.52. *The following sentences are true.*

a) For any $n \in \mathbb{N}_+$ it is true that the initial segment of $\mathbb{N}_+$ up to n is identical with the initial segment of $\mathbb{N}$ up to n without 0, i.e.

$$\{1, \ldots, n\} = \{0, \ldots, n\} \setminus \{0\}. \tag{4.244}$$

b) *For any* $n \in \mathbb{N}$ *it is true that the initial segment of* $\mathbb{N}$ *up to* n *is identical with the initial segment of* $\mathbb{N}_+$ *up to* n *adjoined by* 0*, i.e.*

$$\{0, \ldots, n\} = \{1, \ldots, n\} \cup \{0\}. \tag{4.245}$$

Proof. Concerning a), we carry out a proof by mathematical induction according to Method 4.4. Regarding the base case ($n = 1$), we obtain the equations

$$\begin{aligned}\{1, \ldots, 1\} &= u_{\mathbb{N}_+}(1) = \{1\} = \{0, 1\} \setminus \{0\} = (\{0\} \cup \{1\}) \setminus \{0\} \\ &= (u_{\mathbb{N}}(0) \cup \{0^+\}) \setminus \{0\} = u_{\mathbb{N}}(1) \setminus \{0\} \\ &= \{0, \ldots, 1\} \setminus \{0\}\end{aligned}$$

using (4.238), (4.236), (2.178) in connection with (4.165), then (2.226), (4.87) together with (2.291), subsequently (4.88), and finally (4.92). Thus, the base case holds.

Regarding the induction step, we let n be arbitrary in $\mathbb{N}_+$ (so that $n \in \mathbb{N}$ follows to be true with (2.308) and the definition of a subset), make the induction assumption

$$\{1, \ldots, n\} = \{0, \ldots, n\} \setminus \{0\},$$

and show that this implies $\{1, \ldots, n^+\} = \{0, \ldots, n^+\} \setminus \{0\}$. Let us now observe the truth of the equations

$$\begin{aligned}\{1, \ldots, n^+\} &= \{1, \ldots, n\} \cup \{n^+\} \\ &= (\{0, \ldots, n\} \setminus \{0\}) \cup \{n^+\} \\ &= (\{0, \ldots, n\} \cup \{n^+\}) \setminus \{0\} \\ &= \{0, \ldots, n^+\} \setminus \{0\}\end{aligned}$$

using (4.241), the induction assumption, (2.223) based on the fact that the previously established $n \in \mathbb{N}$ implies $0 \neq n^+$ according to (4.35) and therefore $\{0\} \cap \{n^+\} = \emptyset$ with (2.174), and finally (4.89). As n was arbitrary, we may therefore conclude that the induction step is also true, which completes the proof by mathematical induction of the universal sentence (4.244).

Concerning b), We let $n \in \mathbb{N}$ be arbitrary, so that (2.310) gives the disjunction $n = 0 \lor n \in \mathbb{N}_+$, which we now use to prove the sentence (4.245) by cases. The first case $n = 0$ gives

$$\begin{aligned}\{0, \ldots, n\} &= u_{\mathbb{N}}(n) = u_{\mathbb{N}}(0) = \{0\} = \emptyset \cup \{0\} \\ &= \{1, \ldots, n\} \cup \{0\}\end{aligned}$$

by applying (4.92), substitution based on the case assumption $n = 0$, (4.87), (2.216), and (4.239). The other case $n \in \mathbb{N}_+$ implies $n \in \mathbb{N}$ (as noted already in the proof of a)) and then $0 \in \{0, \ldots, n\}$ with (4.97), so that $\{0\} \subseteq \{0, \ldots, n\}$ follows to be true with (2.184). We then obtain

$$\begin{aligned}\{0, \ldots, n\} &= (\{0, \ldots, n\} \setminus \{0\}) \cup \{0\} \\ &= \{1, \ldots, n\} \cup \{0\}\end{aligned}$$

by using (2.263) in connection with the preceding inclusion and (4.244). Thus, (4.245) is true in any case, and since n was arbitrary, it follows that b) also holds. □

Corollary 4.53. *For any $n \in \mathbb{N}$ the initial segment of $\mathbb{N}_+$ up to n is included in the initial segment of $\mathbb{N}$ up to n, i.e.*

$$\{1, \ldots, n\} \subseteq \{0, \ldots, n\}. \tag{4.246}$$

Proof. Letting n be an arbitrary natural number, the inclusion of $\{1, \ldots, n\}$ in $\{0, \ldots, n\}$ follows immediately with (2.201) from (4.245), which is then true for any n. □

The following corollary is derived from Proposition 4.13 and Exercise 4.4.

Corollary 4.54. *The initial segment of $\mathbb{N}_+$ up to a positive natural number n contains n and 1, i.e.*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow n \in \{1, \ldots, n\}), \tag{4.247}$$

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow 1 \in \{1, \ldots, n\}). \tag{4.248}$$

Next, we restate the properties listed in Proposition 4.15 and in Proposition 4.17 for the counting domain $(\mathbb{N}_+, s^+ \upharpoonright \mathbb{N}_+, 1)$.

Corollary 4.55. *The following sentences are true.*

a) If the successor of a positive natural number m is element of the initial segment of $\mathbb{N}_+$ up to a positive natural number n, then m is also element of this initial segment, i.e.

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m^+ \in \{1, \ldots, n\} \Rightarrow m \in \{1, \ldots, n\}]). \tag{4.249}$$

b) The successor of a positive natural number n is not an element of the initial segment of $\mathbb{N}_+$ up to n, i.e.

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow n^+ \notin \{1, \ldots, n\}). \tag{4.250}$$

c) *If a positive natural number m is element of the initial segment of $\mathbb{N}_+$ up to a positive natural number n where m and n are different, then the successor of m is also element of this initial segment, i.e.*

$$\begin{aligned}&\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow \\ &\quad [(m \neq n \wedge m \in \{1, \ldots, n\}) \Rightarrow m^+ \in \{1, \ldots, n\}]).\end{aligned} \tag{4.251}$$

d) *The function $u_{\mathbb{N}_+}$ is an injection, i.e.*

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [\{1, \ldots, m\} = \{1, \ldots, n\} \Rightarrow m = n]). \tag{4.252}$$

e) *If the initial segment of $\mathbb{N}_+$ up to a positive natural number m is a proper subset of the initial segment of $\mathbb{N}_+$ up to a positive natural number n, then the initial segment of $\mathbb{N}_+$ up to the successor of m is included in the initial segment of $\mathbb{N}_+$ up to n, i.e.*

$$\begin{aligned}&\forall m, n\,([m, n \in \mathbb{N}_+ \Rightarrow \\ &\quad [\{1, \ldots, m\} \subset \{1, \ldots, n\} \Rightarrow \{1, \ldots, m^+\} \subseteq \{1, \ldots, n\}]).\end{aligned} \tag{4.253}$$

f) *The initial segment of $\mathbb{N}_+$ up to any positive natural number n is a proper subset of the initial segment of $\mathbb{N}_+$ up to the successor of n, i.e.*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \{1, \ldots, n\} \subset \{1, \ldots, n^+\}). \tag{4.254}$$

g) *The initial segment of $\mathbb{N}_+$ up to a positive natural number n and the singleton formed by the successor of n are disjoint, that is,*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \{1, \ldots, n\} \cap \{n^+\} = \emptyset). \tag{4.255}$$

h) *The initial segment of $\mathbb{N}_+$ up to a positive natural number n equals the difference of the initial segment of $\mathbb{N}_+$ up to the successor of n and the singleton formed by that successor, that is,*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \{1, \ldots, n\} = \{1, \ldots, n^+\} \setminus \{n^+\}). \tag{4.256}$$

i) *The singleton formed by the successor of a positive natural number n equals the difference of the initial segment of $\mathbb{N}_+$ up to the successor of n and the initial segment up to n, i.e.*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \{n^+\} = \{1, \ldots, n^+\} \setminus \{1, \ldots, n\}). \tag{4.257}$$

In the following, we restate the findings of Theorem 4.19 and Theorem 4.20, for the counting domain based on the positive natural numbers, which yield the subsequent definitions for the orderings $\leq_{\mathbb{N}_+}$ and $<_{\mathbb{N}_+}$.

Corollary 4.56. *The following sentences are true.*

a) The total ordering $\leq_{\mathbb{N}_+}$ *of* $\mathbb{N}_+$ *(defined according to Theorem 4.19) satisfies*

$$\forall m,n\,(m,n\in\mathbb{N}_+\Rightarrow[m\leq_{\mathbb{N}_+}n\Leftrightarrow\{1,\ldots,m\}\subseteq\{1,\ldots,n\}]),\tag{4.258}$$

and

$$\forall n\,(n\in\mathbb{N}_+\Rightarrow n<_{\mathbb{N}_+}n^+).\tag{4.259}$$

b) Then, the linear ordering $<_{\mathbb{N}_+}$ *of* $\mathbb{N}_+$ *induced by* $\leq_{\mathbb{N}_+}$ *satisfies*

$$\forall m,n\,(m,n\in\mathbb{N}_+\Rightarrow[m<_{\mathbb{N}_+}n\Leftrightarrow\{1,\ldots,m\}\subset\{1,\ldots,n\}]),\tag{4.260}$$

Definition 4.5 (Standard total & linear ordering of $\mathbb{N}_+$**).** We call $\leq_{\mathbb{N}_+}$ the *standard total ordering of* $\mathbb{N}_+$ and $<_{\mathbb{N}_+}$ the *standard linear ordering of* $\mathbb{N}_+$.

The relationships established in Proposition 4.52 allow us to bring out clearly the useful fact that it is irrelevant whether we use the total ordering $\leq_{\mathbb{N}_+}$ or $\leq_{\mathbb{N}}$ to compare two positive natural numbers.

Proposition 4.57. *The following sentence is true.*

$$\forall m,n\,(m,n\in\mathbb{N}_+\Rightarrow[m\leq_{\mathbb{N}_+}n\Leftrightarrow m\leq_{\mathbb{N}}n]).\tag{4.261}$$

Proof. We let m and n be arbitrary in $\mathbb{N}_+$ and observe first the truth of the equivalence

$$m\leq_{\mathbb{N}_+}n\;\Leftrightarrow\;\{1,\ldots,m\}\subseteq\{1,\ldots,n\}\tag{4.262}$$

in light of (4.258). Similarly, we obtain

$$m\leq_{\mathbb{N}}n\;\Leftrightarrow\;\{0,\ldots,m\}\subseteq\{0,\ldots,n\}\tag{4.263}$$

by applying (4.152). We now prove the first part ('$\Rightarrow$') of the proposed equivalence, assuming $m\leq_{\mathbb{N}_+}n$, which implies $\{1,\ldots,m\}\subseteq\{1,\ldots,n\}$ with (4.262), and then furthermore

$$\{1,\ldots,m\}\cup\{0\}\subseteq\{1,\ldots,n\}\cup\{0\}$$

with (2.251). This yields $\{0,\ldots,m\}\subseteq\{0,\ldots,n\}$ by applying substitution based on (4.245), and therefore $m\leq_{\mathbb{N}}n$ with (4.263), which proves the first part of the equivalence in (4.261).

To prove the second part ('$\Leftarrow$'), we now assume $m \leq_{\mathbb{N}} n$ to be true, which implies $\{0, \ldots, m\} \subseteq \{0, \ldots, n\}$ with (4.263). It then follows with (2.190) that

$$\{0, \ldots, m\} \setminus \{0\} \subseteq \{0, \ldots, n\} \setminus \{0\}$$

holds, so that we obtain $\{1, \ldots, m\} \subseteq \{1, \ldots, n\}$ with (4.244), which further implies $m \leq_{\mathbb{N}_+} n$ with (4.262), completing the proof of the equivalence. As m and n were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Exercise 4.14. Establish the following sentence.

$$\forall m, n\, (m, n \in \mathbb{N}_+ \Rightarrow [m <_{\mathbb{N}_+} n \Leftrightarrow m <_{\mathbb{N}} n]). \tag{4.264}$$

(Hint: Use (4.261) in connection with Theorem 3.86 and Theorem 3.49.)

Proposition 4.58. *The standard total ordering of* $\mathbb{N}_+$ *is included in the standard total ordering* $\mathbb{N}$*, that is,*

$$\leq_{\mathbb{N}_+} \;\subseteq\; \leq_{\mathbb{N}} . \tag{4.265}$$

Proof. We use the definition of a subset and prove equivalently

$$\forall z\, (z \in \leq_{\mathbb{N}_+} \Rightarrow z \in \leq_{\mathbb{N}}). \tag{4.266}$$

For this purpose, we let $z \in \leq_{\mathbb{N}_+}$ be arbitrary, so that there exist by definition of a binary relation constants, say $\bar{m}$ and $\bar{n}$, such that $z = (\bar{m}, \bar{n})$ holds. Thus, we have $(\bar{m}, \bar{n}) \in \leq_{\mathbb{N}_+}$, which we may write as $\bar{m} \leq_{\mathbb{N}_+} \bar{n}$, using Notation 3.2. As a partial ordering of $\mathbb{N}_+$, we have that $\leq_{\mathbb{N}_+}$ is a binary relation on $\mathbb{N}_+$ and therefore a subset of the Cartesian product $\mathbb{N}_+ \times \mathbb{N}_+$. It then follows from $(\bar{m}, \bar{n}) \in \leq_{\mathbb{N}_+}$ with the definition of a subset that $(\bar{m}, \bar{n}) \in \mathbb{N}_+ \times \mathbb{N}_+$ holds, which implies $\bar{m}, \bar{n} \in \mathbb{N}_+$ by definition of the Cartesian product of two sets. With this finding, the previously established $\bar{m} \leq_{\mathbb{N}_+} \bar{n}$ yields $\bar{m} \leq_{\mathbb{N}} \bar{n}$ with (4.261), which we may write as $[z =]\ (\bar{m}, \bar{n}) \in \leq_{\mathbb{N}}$. Thus, $z \in \leq_{\mathbb{N}}$ holds, which proves the implication in (4.266). Since z was arbitrary, we may therefore conclude that the universal sentence (4.266) is true, so that the equivalent inclusion (4.265) holds, as claimed. □

Exercise 4.15. Show that the standard linear ordering of $\mathbb{N}_+$ is included in the standard linear ordering $\mathbb{N}$, that is,

$$<_{\mathbb{N}_+} \;\subseteq\; <_{\mathbb{N}} . \tag{4.267}$$

(Hint: Proceed in analogy to the proof of Proposition 4.58, using now (4.264).)

Proposition 4.59. *The successor function s^+ with respect to the counting domain $(\mathbb{N}, s^+, 0)$ is an order-isomorphism from $(\mathbb{N}, \leq_{\mathbb{N}})$ to $(\mathbb{N}_+, \leq_{\mathbb{N}_+})$, i.e.*

$$s^+ : (\mathbb{N}, \leq_{\mathbb{N}}) \rightleftarrows (\mathbb{N}_+, \leq_{\mathbb{N}_+}). \tag{4.268}$$

Proof. Let us first recall that s^+ is a bijection from $\mathbb{N}$ to $\mathbb{N}_+$, according to Corollary 4.8. To show that s^+ is also an order-embedding from $(\mathbb{N}, \leq_{\mathbb{N}})$ to $(\mathbb{N}_+, \leq_{\mathbb{N}_+})$, we verify

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \leq_{\mathbb{N}} n \Leftrightarrow s^+(m) \leq_{\mathbb{N}_+} s^+(n)]). \tag{4.269}$$

We let m and n be arbitrary in $\mathbb{N}$ and notice that $s^+(m)$ and $s^+(n)$ are elements of the range $\mathbb{N}_+$ of s^+. We then obtain the equivalences

$$\begin{aligned} m \leq_{\mathbb{N}} n &\Leftrightarrow m^+ \leq_{\mathbb{N}} n^+ \\ &\Leftrightarrow m^+ \leq_{\mathbb{N}_+} n^+ \\ &\Leftrightarrow s^+(m) \leq_{\mathbb{N}_+} s^+(n) \end{aligned}$$

using (4.163), (4.261), and the notation in (4.33) for the successor of a natural number. As m and n were arbitrary, it follows that (4.269) is true, which proves that s^+ is an order-embedding from $(\mathbb{N}, \leq_{\mathbb{N}})$ to $(\mathbb{N}_+, \leq_{\mathbb{N}_+})$. Together with the finding that s^+ is a bijection, this gives (4.268), by definition of an order-isomorphism. □

We now use the fact that the total orderings $\leq_{\mathbb{N}_+}$ and $\leq_{\mathbb{N}}$ as well as the linear orderings $<_{\mathbb{N}_+}$ and $<_{\mathbb{N}}$ coincide for ordered pairs of positive natural number (according to Proposition 4.57 and Exercise 4.14, respectively) to restate for the counting domain $(\mathbb{N}_+, s^+ \upharpoonright \mathbb{N}_+, 1)$ the generic findings of

- Exercises 4.5, 4.6,
- Propositions 4.24, 4.26, 4.28, 4.30,
- Exercise 4.8,
- Theorem 4.34 (Characterization of initial segments),
- Propositions 4.36, 4.40, 4.42,
- and Corollary 4.43.

Corollary 4.60. *The following sentences are true.*

a) If a positive natural number m is less than a positive natural number n, then the successor of m is less than or equal to n, that is,

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m <_{\mathbb{N}} n \Rightarrow m^+ \leq_{\mathbb{N}} n]). \tag{4.270}$$

b) If the successor of a positive natural number m is less than or equal to the successor of a positive natural number n, then m is less than or equal to n, i.e.

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m^+ \leq_{\mathbb{N}} n^+ \Rightarrow m \leq_{\mathbb{N}} n]). \tag{4.271}$$

c) If the successor of a positive natural number m is less than the successor of a positive natural number n, then m is less than n, i.e.

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m^+ <_{\mathbb{N}} n^+ \Rightarrow m <_{\mathbb{N}} n]). \tag{4.272}$$

d) A positive natural number m is less than or equal to a positive natural number n iff the successor of m is less than or equal to the successor of n, i.e.

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m \leq_{\mathbb{N}} n \Leftrightarrow m^+ \leq_{\mathbb{N}} n^+]). \tag{4.273}$$

e) The linearly ordered set $(\mathbb{N}_+, \leq_{\mathbb{N}_+})$ is a lattice.

f) The set of positive natural numbers does not have an upper bound with respect to $\leq_{\mathbb{N}}$.

g) The successor m^+ of a positive natural number m is the next greater positive natural number after m, i.e.

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m <_{\mathbb{N}} n \wedge n \leq_{\mathbb{N}} m^+] \Rightarrow n = m^+). \tag{4.274}$$

h) The initial segment of $\mathbb{N}_+$ up to a positive natural number n consists of all positive natural numbers that are less than or equal to n, i.e.

$$\forall m, n\,(m, n \in \mathbb{N}_+ \Rightarrow [m \in \{1, \ldots, n\} \Leftrightarrow m \leq_{\mathbb{N}} n]). \tag{4.275}$$

Moreover, it is true for any positive natural number n that all elements of the initial segment of $\mathbb{N}_+$ up to n are between 1 and n, where 1 is the least and n the greatest element of that initial segment, i.e.

$$\min\{1, \ldots, n\} = 1, \tag{4.276}$$

$$\max\{1, \ldots, n\} = n. \tag{4.277}$$

i) 1 is a lower bound for $\mathbb{N}_+$, i.e.

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow 1 \leq_{\mathbb{N}} n), \tag{4.278}$$

and 1 is also the least element of $\mathbb{N}_+$.

j) *For any positive natural number* n *it is false that* n *is less than* 1, *i.e.*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \neg n <_{\mathbb{N}} 1). \tag{4.279}$$

k) *There is no positive natural number which is less than* 1, *i.e.*

$$\neg\exists n\,(n \in \mathbb{N}_+ \,\wedge\, n <_{\mathbb{N}} 1). \tag{4.280}$$

l) *Every nonempty subset of the initial segment of* $\mathbb{N}_+$ *up to a positive natural number* n *has a greatest element, i.e.*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \forall A\,([A \subseteq \{1,\ldots,n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \max A))). \tag{4.281}$$

Moreover, any nonempty and bounded-from-above subset of $\mathbb{N}_+$ *has a greatest element, i.e.*

$$\begin{aligned}&\forall A\,([A \subseteq \mathbb{N}_+ \,\wedge\, A \neq \emptyset \,\wedge\, \exists u\,(u \in \mathbb{N}_+ \,\wedge\, \forall k\,(k \in A \Rightarrow k \leq_{\mathbb{N}} u)]\\ &\quad\Rightarrow \exists m\,(m = \max A))).\end{aligned} \tag{4.282}$$

m) *Every nonempty subset of the initial segment of* $\mathbb{N}_+$ *up to a positive natural number* n *has a least element, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \forall A\,([A \subseteq \{0,\ldots,n\} \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \min A))). \tag{4.283}$$

Furthermore, any nonempty subset of $\mathbb{N}_+$ *has a least element, i.e.*

$$\forall A\,([A \subseteq \mathbb{N}_+ \,\wedge\, A \neq \emptyset] \Rightarrow \exists m\,(m = \min A))). \tag{4.284}$$

n) *The lattice* $(\mathbb{N}_+, \leq_{\mathbb{N}_+})$ *is well-ordered.*

Proposition 4.61. *The restriction of the successor function* s^+ *to a natural number* n *is a bijection from* n *to the initial segment of* $\mathbb{N}_+$ *up to* n, *i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow s^+ \upharpoonright n : n \rightleftarrows \{1,\ldots,n\}). \tag{4.285}$$

Proof. We let n be arbitrary in $\mathbb{N}$ and recall from (4.40) that s^+ is the bijection $s^+ : \mathbb{N} \rightleftarrows \mathbb{N}_+$, so that s^+ is in particular an injection from n to $\mathbb{N}_+$. According to (2.320), we have $n \subseteq \mathbb{N}$, so that $s^+ \upharpoonright n$ is an injection from n to $\mathbb{N}_+$ due to Proposition 3.187.

Next, we verify that the range of $s^+ \upharpoonright n$ is identical with $\{1,\ldots,n\}$, by considering the two cases $n = 0$ and $n \neq 0$. In the first case, we have $n = 0 = \emptyset$ and then $\{1,\ldots,n\} = \emptyset$ with (4.239); furthermore, the domain of the restriction $s^+ \upharpoonright n = s^+ \upharpoonright \emptyset$ is then the empty set due to Proposition

3.164, so that this restriction is itself identical with $\emptyset$ due Proposition 3.151. As the empty function is a bijection from $\emptyset$ to $\emptyset$ (see Corollary 3.201), we then see in light of the previous findings that $s^+ \upharpoonright n$ is a bijection from n to $\{1, \ldots, n\}$ in case of $n = 0$.

In the other case of $n \neq 0$, we have $n \neq \emptyset$ by definition of the zero 0, so that the domain n of $s^+ \upharpoonright n$ is now nonempty. It then follows with Exercise 3.19 that the range of (the binary relation) $s^+ \upharpoonright n$ is also nonempty. We also notice that $n \neq 0$ implies $n \in \mathbb{N}_+$ with (2.310). We therefore obtain with Proposition 4.13 $n \in \{1, \ldots, n\}$, which shows that the stated initial segment is also nonempty in case of $n \neq 0$. Based on these observations, we now apply the Equality Criterion for sets and prove $\mathrm{ran}(s^+ \upharpoonright n) = \{1, \ldots, n\}$ by verifying the equivalent

$$\forall m \, (m \in \mathrm{ran}(s^+ \upharpoonright n) \Leftrightarrow m \in \{1, \ldots, n\}). \tag{4.286}$$

To do this, we let m be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $m \in \mathrm{ran}(s^+ \upharpoonright n)$ to be true (recalling our previous observation that the range indeed has an element). We already showed that $s^+ \upharpoonright n$ is a function with codomain $\mathbb{N}_+$, so that $\mathrm{ran}(s^+ \upharpoonright n) \subseteq \mathbb{N}_+$ holds. With this, the assumption $m \in \mathrm{ran}(s^+ \upharpoonright n)$ implies $m \in \mathbb{N}_+$ with the definition of a subset. Moreover, it follows by definition of a range that there exists a constant, say $\bar{k}$, such that $(\bar{k}, m) \in s^+ \upharpoonright n$ holds, which in turn implies $(\bar{k}, m) \in s^+$ and $\bar{k} \in n$ by definition of a restriction. On the one hand, the former may be written as $m = s^+(\bar{k}) = \bar{k}^+$, using the notations for a function and for a successor. On the other hand, $\bar{k} \in n$ implies $\bar{k} \in \mathbb{N}$ with the previously mentioned inclusion $n \subseteq \mathbb{N}$, so that we obtain $\bar{k} <_{\mathbb{N}} n$ with (4.190), which inequality implies $\bar{k}^+ \leq_{\mathbb{N}} n$ with (4.157). Let us now observe that $\bar{k} \in \mathbb{N}$ gives $\bar{k}^+ \neq 0$ with Property 1 of a counting domain and therefore $\bar{k}^+ \in \mathbb{N}_+$ according to (2.310). Since $n \in \mathbb{N}_+$ also holds, $\bar{k}^+ \leq_{\mathbb{N}} n$ implies $\bar{k}^+ \in \{1, \ldots, n\}$ with the Characterization of initial segments (4.275), and thus the desired $m \in \{1, \ldots, n\}$ via substitution based on the previously established equation $m = \bar{k}^+$. Thus, the first part of the equivalence in (4.286) holds.

To prove the second part ('$\Leftarrow$'), we now assume $m \in \{1, \ldots, n\}$ to be true, which implies $m \in \mathbb{N}_+$ (by definition of an initial segment of $\mathbb{N}_+$ for $n \in \mathbb{N}_+$) and then also $m \leq_{\mathbb{N}} n$ with (4.275). Here, $m \in \mathbb{N}_+$ implies $m \in \mathbb{N}$ and $m \neq 0$ (by definition of $\mathbb{N}_+$). It then follows from the latter two findings with (4.39) that there exists an element of $\mathbb{N}$, say $\bar{k}$, such that $\bar{k} \neq m$ and $\bar{k}^+ = m$ hold. We may write the latter equation as $s^+(\bar{k}) = m$ (using the notation for successors), and then that equation as

$$(\bar{k}, m) \in s^+. \tag{4.287}$$

Furthermore, $\bar{k} \in \mathbb{N}$ implies $\bar{k} <_{\mathbb{N}} \bar{k}^{+}$ with (4.153), so that substitution based on the previously established equation $\bar{k}^{+} = m$ yields $\bar{k} <_{\mathbb{N}} m$. The conjunction of this and the previously obtained $m \leq_{\mathbb{N}} n$ then implies $\bar{k} <_{\mathbb{N}} n$ with the Transitivity Formula for $<$ and $\leq$, and therefore

$$\bar{k} \in n \tag{4.288}$$

with (4.190). Now, the conjunction of (4.287) and (4.288) implies with the definition of a restriction$(\bar{k}, m) \in s^{+} \upharpoonright n$, and the definition of a range then gives the desired $m \in \mathrm{ran}(s^{+} \upharpoonright n)$, completing the proof of the equivalence. As m is arbitrary, we may therefore conclude that the universal sentence (4.286) is true, so that the equation $\mathrm{ran}(s^{+} \upharpoonright n) = \{1, \ldots, n\}$ also holds, according to the Equality Criterion for sets. Consequently, the function

$$s^{+} \upharpoonright n : n \to \{1, \ldots, n\} \tag{4.289}$$

is a surjection by definition. Since $s^{+} \upharpoonright n : n \to \mathbb{N}_{+}$ is an injection, it follows with Note 3.23 that (4.289) is also an injection. Thus, (4.289) is a bijection by definition, which proves the implication in (4.285) also in the case of $n \neq 0$. As n was arbitrary, it then follows that the proposed universal sentence is true. □

Proposition 4.62. *For any $m, n \in \mathbb{N}$ there exists a unique set $\{m^{+}, \ldots, n\}$ consisting of all natural numbers between m^{+} and n in the sense of*

$$\forall k \, (k \in \{m^{+}, \ldots, n\} \Leftrightarrow [k \in \mathbb{N} \wedge m^{+} \leq_{\mathbb{N}} k \leq_{\mathbb{N}} n]). \tag{4.290}$$

and this set is identical with the difference of the initial segment of $\mathbb{N}_{+}$ up to n and the initial segment of $\mathbb{N}_{+}$ up to m, i.e.

$$\{m^{+}, \ldots, n\} = \{1, \ldots, n\} \setminus \{1, \ldots, m\}. \tag{4.291}$$

Proof. Letting m and n be arbitrary natural numbers, we may apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true uniquely existential sentence

$$\exists! \{m^{+}, \ldots, n\} \, \forall k \, (k \in \{m^{+}, \ldots, n\} \Leftrightarrow [k \in \mathbb{N} \wedge m^{+} \leq_{\mathbb{N}} k \wedge k \leq_{\mathbb{N}} n]). \tag{4.292}$$

Thus, the set $\{m^{+}, \ldots, n\}$ satisfies (4.290).

Next, to establish the equation (4.291), we apply the Equality Criterion for sets and accordingly verify the universal sentence

$$\forall k \, (k \in \{m^{+}, \ldots, n\} \Leftrightarrow k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}), \tag{4.293}$$

letting k be arbitrary. To prove the first part ('$\Rightarrow$') of the equivalence directly, we assume $k \in \{m^+, \ldots, n\}$, so that the inequalities

$$[m <_{\mathbb{N}}] \quad m^+ \leq_{\mathbb{N}} k \leq_{\mathbb{N}} n$$

follow to be true with (4.290) and (4.153). Here, $k \leq_{\mathbb{N}} n$ implies $k \in \{0, \ldots, n\}$ with (4.180) according to the Characterization of initial segments, and the inequalities $m <_{\mathbb{N}} m^+ \leq_{\mathbb{N}} k$ imply $m <_{\mathbb{N}} k$ with the Transitivity Formula for $<$ and $\leq$. The latter further implies $\neg k \leq_{\mathbb{N}} m$ with the Negation Formula for $\leq$ and consequently $\neg k \in \{0, \ldots, m\}$ (using again the Characterization of initial segments). Since $\{1, \ldots, m\}$ is included in $\{0, \ldots, m\}$ according to Corollary 4.53, it then follows from the preceding finding $k \notin \{0, \ldots, m\}$ that $k \notin \{1, \ldots, m\}$ holds, applying (2.9). Now, we also have that $m^+ \neq 0$ is true because of Property 1 of a counting domain; since $m^+ <_{\mathbb{N}} 0$ is also false in view of (4.188), it follows with the comparability of the linear ordering $<_{\mathbb{N}}$ that $0 <_{\mathbb{N}} m^+ \; [\leq_{\mathbb{N}} k]$ holds. These two inequalities give $0 <_{\mathbb{N}} k$ with the Transitivity Formula for $<$ and $\leq$, so that we obtain $k \neq 0$ (utilizing again the comparability of $<_{\mathbb{N}}$), which inequality then implies $k \notin \{0\}$ with (2.169). As $k \in \{0, \ldots, n\}$ and $k \notin \{0\}$ are simultaneously true, it follows with (4.244) in connection with the definition of a set difference that $k \in \{1, \ldots, n\}$ holds. Together with the previously established $k \notin \{1, \ldots, m\}$, this yields $k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}$ by definition of a set difference, proving the first part of the equivalence in (4.293).

We now prove the sentence '$\Leftarrow$' by cases, based on the fact that the disjunction $n = 0 \vee n \neq 0$ is true according to the Law of the Excluded Middle. In the first case of $n = 0$, we obtain $\{1, \ldots, n\} = \emptyset$ with (4.239) and therefore

$$\{1, \ldots, n\} \setminus \{1, \ldots, m\} = \emptyset \setminus \{1, \ldots, m\} = \emptyset \tag{4.294}$$

with (2.105). Thus, the antecedent $k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}$ $(= \emptyset)$ is false by definition of the empty set, so that the implication ('$\Leftarrow$') itself is true.

The other case $n \neq 0$ implies $n \notin \{0\}$ with (2.169) and the Law of Contraposition, which inequality yields with the initial assumption $n \in \mathbb{N}$ and the definition of a set difference $n \in \mathbb{N} \setminus \{0\}$. This gives $n \in \mathbb{N}_+$ with the definition of the set of positive natural numbers, so that $\{1, \ldots, n\}$ is nonempty by definition of an initial segment. Now, since $n \leq_{\mathbb{N}} m \vee \neg n \leq_{\mathbb{N}} m$ is true by the Law of the Excluded Middle, we may use this true disjunction to prove the implication '$\Leftarrow$' by cases.

If $n \leq_{\mathbb{N}} m$ holds, then we may prove by contradiction that the antecedent $k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}$ of the implication ('$\Leftarrow$') to be proven is again false. Assuming $k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}$ to be true, it follows (by definition of a set difference) that $k \in \{1, \ldots, n\}$ and $k \notin \{1, \ldots, m\}$ both hold.

The former implies $k \leq_{\mathbb{N}} n$ and the latter $\neg k \leq_{\mathbb{N}} m$ with (4.275). Here, the latter negation further implies $m <_{\mathbb{N}} k$ with the Negation Formula for $\leq$. The conjunction of this inequality and the previously established $k \leq_{\mathbb{N}} n$ then yields $m <_{\mathbb{N}} n$ with the Transitivity Formula for $<$ and $\leq$, and therefore $\neg n \leq_{\mathbb{N}} m$ (again with the Negation Formula for $\leq$). This negation evidently contradicts the subcase assumption $n \leq_{\mathbb{N}} m$, completing the proof that the antecedent of the implication ('$\Leftarrow$') in (4.293) is false. Consequently, the implication itself is true for the first subcase.

If the second subcase $\neg n \leq_{\mathbb{N}} m$ holds, then also $m <_{\mathbb{N}} n$ because of the Negation Formula for $\leq$, and we may prove the implication ('$\Leftarrow$') directly. Assuming the antecedent $k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}$ to be true, we obtain – as for the first subcase – the true conjunction of $k \in \{1, \ldots, n\}$ and $k \notin \{1, \ldots, m\}$, again with the consequences $k \leq_{\mathbb{N}} n$ and $m <_{\mathbb{N}} k$. Since the latter implies $m^+ \leq_{\mathbb{N}} k$ with (4.157), we have in combination with the former inequality $k \leq_{\mathbb{N}} n$ that $m^+ \leq_{\mathbb{N}} k \leq_{\mathbb{N}} n$ holds, which evidently yields $k \in \{m^+, \ldots, n\}$ with (4.290). This completes the direct proof of the implication ('$\Leftarrow$') for the second subcase and thus the two proofs nested proofs by cases. Since k was arbitrary, the universal sentence (4.293) follows therefore to be true. Consequently, the sets $\{m^+, \ldots, n\}$ and $\{1, \ldots, n\} \setminus \{1, \ldots, m\}$ turn out to be identical (in view of the Equality Criterion for sets), so that the proof of the equation (4.291) is complete. Since m and n were arbitrary, we may now finally conclude that the proposition holds. $\square$

Note 4.11. A comparison of (4.292) with (3.351) reveals for any $m, n \in \mathbb{N}$ that the set $\{m^+, \ldots, n\}$ is identical with the closed interval $[m^+, n]$ in $\mathbb{N}$ with respect to $\mathbb{N}$, that is,

$$\forall m, n\, (m, n \in \mathbb{N} \Rightarrow \{m^+, \ldots, n\} = [m^+, n]). \tag{4.295}$$

We call $\{m^+, \ldots, n\}$ also the *intermediate segment of* $\mathbb{N}_+$ *from* m^+ *to* n.

Corollary 4.63. *The following sentences are true.*

$$\forall m\, (m \in \mathbb{N} \Rightarrow \{m^+, \ldots, 0\} = \emptyset), \tag{4.296}$$

$$\forall m, n\, ([m, n \in \mathbb{N} \wedge n \leq_{\mathbb{N}} m] \Rightarrow \{m^+, \ldots, n\} = \emptyset). \tag{4.297}$$

Proof. On the one hand, letting $m \in \mathbb{N}$ be arbitrary, the truth of (4.296) follows from (4.294) and (4.291). On the other hand, letting $m, n \in \mathbb{N}$ be arbitrary such that $n \leq_{\mathbb{N}} m$ holds, the truth of

$$\forall k\, (k \notin \{m^+, \ldots, n\})$$

follows by letting k be arbitrary and recalling from the proof of Proposition 4.291 that $n \leq_{\mathbb{N}} m$ implies that $k \in \{1, \ldots, n\} \setminus \{1, \ldots, m\}$ is false, so that $k \notin \{m^+, \ldots, n\}$ follows to be true with (4.291). Since k is arbitrary, we may therefore conclude in view of the definition of the empty set that $\{m^+, \ldots, n\} = \emptyset$ holds, which proves (4.297). As m and n were also arbitrary, it then follows that the universal sentences a) and b) are true. $\square$

Corollary 4.64. *The intermediate segment (of* $\mathbb{N}_+$*) from the successor of a natural number* m *to a natural number* n *is included in the initial segment of* $\mathbb{N}_+$ *up to* n*, that is,*

$$\forall m, n\, (m, n \in \mathbb{N} \Rightarrow \{m^+, \ldots, n\} \subseteq \{1, \ldots, n\}). \tag{4.298}$$

Proof. Letting $m, n \in \mathbb{N}$ be arbitrary, we obtain the inclusion in (4.291) immediately from (4.291) by applying (2.125). $\square$

Proposition 4.65. *The following implication holds for any* $m, n \in \mathbb{N}$.

$$m \leq_{\mathbb{N}} n \;\Rightarrow\; \{1, \ldots, m\} \cup \{m^+, \ldots, n\} = \{1, \ldots, n\}. \tag{4.299}$$

Proof. We let m and n be arbitrary natural numbers, assume $m \leq_{\mathbb{N}} n$ to be true, and we prove the equation in (4.299) by means of the Equality Criterion for sets, verifying accordingly

$$\forall k\, (k \in \{1, \ldots, m\} \cup \{m^+, \ldots, n\} \Leftrightarrow k \in \{1, \ldots, n\}). \tag{4.300}$$

For this purpose, we take an arbitrary k and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $k \in \{1, \ldots, m\} \cup \{m^+, \ldots, n\}$ to be true. By definition of the union of two sets, the disjunction

$$k \in \{1, \ldots, m\} \vee k \in \{m^+, \ldots, n\} \tag{4.301}$$

is then also true, which we now use to prove the desired consequent $k \in \{1, \ldots, n\}$ by cases. The first case $k \in \{1, \ldots, m\}$ implies the truth of $k \in \mathbb{N}$, $1 \leq_{\mathbb{N}} k$ and $k \leq_{\mathbb{N}} m$ with (4.290), where the latter yields together with the initial assumption $m \leq_{\mathbb{N}} n$ in view of the transitivity of the standard total ordering $\leq_{\mathbb{N}}$ the inequality $k \leq_{\mathbb{N}} n$. Thus, $k \in \mathbb{N}$, $1 \leq_{\mathbb{N}} k$ and $k \leq_{\mathbb{N}} n$ are all true, so that $k \in \{1, \ldots, n\}$ follows to be true according to (4.290). The second case $k \in \{m^+, \ldots, n\}$ gives with the already established inclusion (4.298) and the definition of a subset $k \in \{1, \ldots, n\}$, which thus holds in any case, so that the proof of the first part of the equivalence is complete.

To prove the second part ('$\Leftarrow$') in (4.300) , we now assume $k \in \{1, \ldots, n\}$ to be true, so that we evidently have $k \in \mathbb{N}$, $1 \leq_{\mathbb{N}} k$ and $k \leq_{\mathbb{N}} n$. Observing that the Law of the Excluded Middle gives the true disjunction $k \leq_{\mathbb{N}} m \vee \neg k \leq_{\mathbb{N}} m$, we now prove the disjunction (4.301) by cases. The first case $k \leq_{\mathbb{N}} m$ implies together with $k \in \mathbb{N}$ and $1 \leq_{\mathbb{N}} k$ that $k \in \{1, \ldots, m\}$ holds, so that the disjunction to be proven is also true. The second case $\neg k \leq_{\mathbb{N}} m$ implies with the Negation Formula for $\leq$ first $m <_{\mathbb{N}} k$ and then evidently $m^+ \leq_{\mathbb{N}} k$ with (4.270). This inequality in turn implies together with $k \in \mathbb{N}$ and $k \leq_{\mathbb{N}} n$ that $k \in \{m^+, \ldots, n\}$ holds. Then, the disjunction (4.301) is again true, so that the proof by cases is complete. Consequently, the desired consequent of the second part ('$\Leftarrow$') of the equivalence in (4.300) follows to be true by definition of the union of two sets.

As k was arbitrary, we may therefore conclude that the universal sentence (4.300) holds, so that the equation in (4.299) follows to be true. Thus, the proof of the implication (4.299) is complete as well. As m and n were arbitrary, we may conclude that the proposed universal sentence is true. $\square$

Exercise 4.16. Show that the initial segment of $\mathbb{N}_+$ up to a natural number m and the intermediate segment (of $\mathbb{N}_+$) from the successor of m to a natural number n are disjoint, that is,

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow \{1, \ldots, m\} \cap \{m^+, \ldots, n\} = \emptyset). \tag{4.302}$$

(Hint: Use Definition 2.6 in connection with Method 1.12.)

4.5. Monotone Sequences and Subsequences

Theorem 4.66 (Monotony Criterion for increasing sequences). *For any partially ordered set $(Y, \leq_Y)$ it is true that a sequence $f = (f_n)_{n\in\mathbb{N}}$ in Y is increasing iff any term of the sequence is less than or equal to the succeeding term, i.e. iff*

$$\forall n\,(n \in \mathbb{N} \Rightarrow f_n \leq_Y f_{n^+}). \tag{4.303}$$

Proof. We let Y, $\leq_Y$ and f be arbitrary, assume that $\leq_Y$ is a reflexive partial ordering of Y, and assume that $f = (f_n)_{n\in\mathbb{N}}$ is a sequence in Y.

To prove the first part ('$\Rightarrow$') of the proposed equivalence, we assume that $(f_n)_{n\in\mathbb{N}}$ is increasing, so that

$$\forall m, n\,([m, n \in \mathbb{N} \wedge m <_{\mathbb{N}} n] \Rightarrow f_m \leq_Y f_n) \tag{4.304}$$

holds with (3.961). To show that this implies (4.303), we let n be arbitrary in $\mathbb{N}$ and recall that $n \in \mathbb{N}$ implies $n <_{\mathbb{N}} n^+$ with (4.153). Then, the conjunction of $n, n^+ \in \mathbb{N}$ and $n <_{\mathbb{N}} n^+$ implies the desired $f_n \leq_Y f_{n^+}$ with (4.304). As n is arbitrary, we therefore conclude that (4.303) is true, which proves the first part of the proposed equivalence.

To prove the second part ('$\Leftarrow$'), we now assume (4.303) to be true and verify (4.304), which we may equivalently write as

$$\forall m\,(m \in \mathbb{N} \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow [m <_{\mathbb{N}} n \Rightarrow f_m \leq_Y f_n])) \tag{4.305}$$

by using (1.90). To prove this sentence, we let m be arbitrary in $\mathbb{N}$ and carry out a proof by mathematical induction with respect to n. Regarding the base case ($n = 0$), we need to prove the implication

$$m <_{\mathbb{N}} 0 \;\Rightarrow\; f_m \leq_Y f_0.$$

Let us observe here that the antecedent $m <_{\mathbb{N}} 0$ is false because of (4.188), so that the implication itself is true. Regarding the induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption

$$m <_{\mathbb{N}} n \;\Rightarrow\; f_m \leq_Y f_n, \tag{4.306}$$

and show that this implies

$$m <_{\mathbb{N}} n^+ \;\Rightarrow\; f_m \leq_Y f_{n^+}. \tag{4.307}$$

We prove the latter implication directly, assuming $m <_{\mathbb{N}} n^+$, which implies $m^+ \leq_{\mathbb{N}} n^+$ with (4.157). The latter further implies $m \leq_{\mathbb{N}} n$ with (4.159), so that $m <_{\mathbb{N}} n \vee m = n$ holds according to the Characterization of induced irreflexive partial orderings. We now use this true disjunction to prove the sentence $f_m \leq_Y f_{n^+}$ by cases. On the one hand, if $m <_{\mathbb{N}} n$ is true, then the induction assumption (4.306) gives $f_m \leq_Y f_n$; as $n \in \mathbb{N}$ implies $f_n \leq_Y f_{n^+}$ with the assumption (4.303), the desired inequality $f_m \leq_Y f_{n^+}$ follows from the previous two inequalities with the transitivity of the reflexive partial ordering $\leq_Y$. On the other hand, if $m = n$ is true, then we obtain $f_m = f_n$ (using the fact that f is a function in connection with Corollary 3.150), so that the previously established $f_n \leq_Y f_{n^+}$ gives $f_m \leq_Y f_{n^+}$ via substitution. Thus, the proof by cases is complete, and the truth of the preceding inequality implies then the truth of the implication (4.307). As n was arbitrary, we may therefore conclude that the induction step holds, so that the proof of the universal sentence with respect to n in (4.305) via mathematical induction is now also complete. Since m was also arbitrary, we may further conclude that the universal sentence (4.305) is true, so that the equivalent sentence (4.304) also holds. Thus, the proof of the second part of the proposed equivalence is complete, which equivalence is therefore true. Because Y, $\leq_Y$ and f were initially arbitrary sets, we may finally conclude that the stated theorem is true. □

Theorem 4.67 (Monotony Criterion for strictly increasing sequences). *For any partially ordered set $(Y, <_Y)$ it is true that a sequence $(f_n)_{n \in \mathbb{N}}$ in Y is strictly increasing iff any term of the sequence is less than the succeeding term, i.e. iff*

$$\forall n\,(n \in \mathbb{N} \Rightarrow f_n <_Y f_{n^+}). \tag{4.308}$$

Exercise 4.17. Prove the Monotony Criterion for strictly increasing sequences.

(Hint: Proceed as in the proof of the Monotony Criterion for increasing sequences.)

Corollary 4.68. *The identity function* $\mathrm{id}_{\mathbb{N}}$ *is a strictly increasing sequence.*

Proof. We may view the identity function $\mathrm{id}_{\mathbb{N}} : \mathbb{N} \to \mathbb{N}$ as the sequence $\mathrm{id}_{\mathbb{N}} = (n)_{n \in \mathbb{N}}$ since $\mathrm{id}_{\mathbb{N}}(n) = n$ holds for any $n \in \mathbb{N}$. We also have that $(\mathbb{N}, <_{\mathbb{N}})$ is a partially ordered and moreover that $n <_{\mathbb{N}} n^+$ holds for any $n \in \mathbb{N}$ because of (4.153), so that Theorem 4.67 shows that $\mathrm{id}_{\mathbb{N}} = (n)_{n \in \mathbb{N}}$ is indeed strictly increasing. □

Theorem 4.69 (Monotony Criterion for decreasing sequences). *For any partially ordered set $(Y, \leq_Y)$ it is true that a sequence $f = (f_n)_{n \in \mathbb{N}}$ in Y is decreasing iff any term of the sequence is greater than or equal to the succeeding term, i.e. iff*

$$\forall n\,(n \in \mathbb{N} \Rightarrow f_n \geq_Y f_{n^+}). \tag{4.309}$$

Exercise 4.18. Establish the Monotony Criterion for decreasing sequences.

We now consider in particular monotone sequences of functions.

Theorem 4.70 (Monotony Criteria for sequences of functions). *The following equivalences are true for any sets X and Y, any irreflexive partial ordering $\leq$ of Y and any sequence $f = (f_n)_{n\in\mathbb{N}}$ of functions from X to Y.*

a) The sequence $(f_n)_{n\in\mathbb{N}}$ is increasing with respect to the reflexive partial ordering $\preceq$ of Y^X (as defined in Proposition 3.251) iff the sequence $(f_n(x))_{n\in\mathbb{N}}$ is increasing with respect to $\leq$ for all x in X.

b) The sequence $(f_n)_{n\in\mathbb{N}}$ is decreasing with respect to $\preceq$ iff the sequence $(f_n(x))_{n\in\mathbb{N}}$ is decreasing with respect to $\leq$ for all x in X.

Proof. We let X, Y, $\leq$ and f be arbitrary sets such that $(Y, \leq)$ is partially ordered and such that $f = (f_n)_{n\in\mathbb{N}}$ is a sequence in Y^X. To prove the first part ('$\Rightarrow$') of the proposed equivalence, we assume that $(f_n)_{n\in\mathbb{N}}$ is increasing with respect to the reflexive partial ordering $\preceq$ of Y^X, so that the universal sentence

$$\forall n \, (n \in \mathbb{N} \Rightarrow f_n \preceq f_{n^+}) \tag{4.310}$$

holds according to the Monotony Criterion for increasing sequences. We then let $\bar{x} \in X$ be arbitrary, and we show that $(f_n(\bar{x}))_{n\in\mathbb{N}}$ is increasing with respect to $\leq$, i.e.

$$\forall n \, (n \in \mathbb{N} \Rightarrow f_n(\bar{x}) \leq f_{n^+}(\bar{x})). \tag{4.311}$$

For this purpose, we let $\bar{n} \in \mathbb{N}$ be arbitrary, which implies $f_{\bar{n}} \preceq f_{\bar{n}^+}$ with (4.310), so that the equivalent universal sentence

$$\forall x \, (x \in X \Rightarrow f_{\bar{n}}(x) \leq f_{\bar{n}^+}(x)) \tag{4.312}$$

follows to be true with (3.903). With this, the assumed $\bar{x} \in X$ yields the inequality $f_{\bar{n}}(\bar{x}) \leq f_{\bar{n}^+}(\bar{x})$, proving the the implication in (4.311). As $\bar{n}$ is arbitrary, we may therefore conclude that (4.311) holds, which shows in light of the Monotony Criterion for increasing sequences that the sequence $(f_n(\bar{x}))_{n\in\mathbb{N}}$ is increasing. Since $\bar{x}$ was also arbitrary, we may now infer from this finding the truth of the first part of the proposed equivalence.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume that $(f_n(x))_{n\in\mathbb{N}}$ is increasing for all $x \in X$, and we show that the universal sentence (4.310) follows to be true. To do this, we take an arbitrary $\bar{n} \in \mathbb{N}$ and establish the desired consequent $f_{\bar{n}} \preceq f_{\bar{n}^+}$ by proving the equivalent universal sentence (4.312). Letting $\bar{x} \in X$ be arbitrary, we now see that the particular sequence $(f_n(\bar{x}))_{n\in\mathbb{N}}$ is (by assumption) increasing, so that (4.311) holds. Thus, $\bar{n} \in \mathbb{N}$ implies $f_{\bar{n}}(\bar{x}) \leq f_{\bar{n}^+}(\bar{x})$, and since $\bar{x}$ is arbitrary, we may therefore conclude that the universal sentence (4.312) is indeed true. Consequently, we obtain the inequality $f_{\bar{n}} \preceq f_{\bar{n}^+}$ with (3.903), and as $\bar{n}$ is arbitrary, we may now further conclude that the universal sentence (4.310) also holds. It then follows from this with the Monotony Criterion for increasing sequences that the sequence $(f_n)_{n\in\mathbb{N}}$ is increasing.

We thus completed the proof of the proposed equivalence, and as X, Y, $\leq$ and f were initially arbitrary sets, we may infer from this the truth of Part a) of the stated theorem. □

Exercise 4.19. Establish Part b) of Theorem 4.70.

According to Theorem 3.64, $\subseteq$ defines a reflexive partial ordering of any set system, which fact immediately gives the following particular instances of the monotony criteria for increasing & decreasing sequences.

Corollary 4.71 (Monotony Criteria for sequences of sets). *For any set system $\mathcal{K}$ and any sequence $(A_n)_{n\in\mathbb{N}}$ of sets in $\mathcal{K}$, it is true that*

a) $(A_n)_{n\in\mathbb{N}}$ is isotone (with respect to $\subseteq_{\mathcal{K}}$) iff any term of the sequence is included in the succeeding term, i.e. iff

$$\forall n\, (n \in \mathbb{N} \Rightarrow A_n \subseteq A_{n^+}). \tag{4.313}$$

b) $(A_n)_{n\in\mathbb{N}}$ is antitone (with respect to $\subseteq_{\mathcal{K}}$) iff

$$\forall n\, (n \in \mathbb{N} \Rightarrow A_{n^+} \subseteq A_n). \tag{4.314}$$

Exercise 4.20. Verify that we may replace $\mathbb{N}$ by $\mathbb{N}_+$ in the monotony criteria for increasing and decreasing sequences on $\mathbb{N}$.

Throughout the current exposition we will establish various concepts for the 'limit' of a given sequence, with an increasing degree of generality. At this point, we introduce a first basic notion of 'limit' which we will apply in the specific context of monotone sequences.

Definition 4.6 (Limit of an increasing & decreasing sequence, increasingly & decreasingly convergent sequence). For any partially ordered set $(Y, \leq_Y)$, any sequence $s = (a_n)_{n\in\mathbb{N}}$ in Y and any element $L \in Y$, if $(a_n)_{n\in\mathbb{N}}$ is

(1) increasing and the supremum of the range of $(a_n)_{n\in\mathbb{N}}$ (i.e., $\sup \operatorname{ran}(s)$) exists, then we say that L is the *limit* of $(a_n)_{n\in\mathbb{N}}$, symbolically

$$L = \overset{\leq_Y}{\lim_{n\to\infty}} a_n = \lim_{n\to\infty} a_n, \tag{4.315}$$

if, and only if,

$$L = \overset{\leq_Y}{\sup} \operatorname{ran}(s), \tag{4.316}$$

in which case we say that $(a_n)_{n\in\mathbb{N}}$ *converges increasingly to* L. We also say that an increasing sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y is increasingly convergent iff there exists an $L \in Y$ satisfying (4.316).

(2) decreasing and the infimum of the range of $(a_n)_{n\in\mathbb{N}}$ (i.e., $\inf \operatorname{ran}(s)$) exists, then we say that L is the *limit* of $(a_n)_{n\in\mathbb{N}}$, symbolically

$$L = \overset{\leq_Y}{\lim_{n\to\infty}} a_n = \lim_{n\to\infty} a_n, \tag{4.317}$$

if, and only if,

$$L = \overset{\leq_Y}{\inf} \operatorname{ran}(s), \tag{4.318}$$

in which case we say that $(a_n)_{n\in\mathbb{N}}$ *converges decreasingly to* L. We also say that a decreasing sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y is decreasingly convergent iff there exists an $L \in Y$ which satisfies (4.318).

Note 4.12. In case of a sequence of sets $s = (a_n)_{n\in\mathbb{N}}$, we will usually say that s *converges isotonely/antitonely* rather than s converges increasingly/decreasingly.

Note 4.13. The previous sentences may evidently all be established by replacing $\mathbb{N}$ with $\mathbb{N}_+$.

Corollary 4.72. *The following sentence is true for any set* Ω.

a) Any isotone sequence $s = (A_n)_{n\in\mathbb{N}_+}$ *in the power set of* Ω *converges isotonely to its union, i.e.*

$$\overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n = \bigcup_{n=1}^{\infty} A_n, \tag{4.319}$$

and

b) any antitone sequence $s = (A_n)_{n\in\mathbb{N}_+}$ *in the power set of* Ω *converges antitonely to its intersection, i.e.*

$$\overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n = \bigcap_{n=1}^{\infty} A_n, \tag{4.320}$$

where the limits are taken with respect to the reflexive partial ordering of inclusion ($\subseteq$) of $\mathcal{P}(\Omega)$.

Proof. We let Ω and s be arbitrary sets and assume that $s = (A_n)_{n\in\mathbb{N}_+}$ is a sequence of sets in the power set of Ω, that is, we assume that $s : \mathbb{N}_+ \to \mathcal{P}(\Omega)$ holds. Thus, $\mathrm{ran}(s) \subseteq \mathcal{P}(\Omega)$ holds by definition of a codomain, so that we obtain with Proposition 3.100

$$\bigcup \mathrm{ran}(s) = \sup \mathrm{ran}(s), \tag{4.321}$$

$$\bigcap \mathrm{ran}(s) = \inf \mathrm{ran}(s), \tag{4.322}$$

where the supremum and the infimum are taken with respect to the reflexive partial ordering of inclusion of $\mathcal{P}(\Omega)$. Let us also observe that the definition of the union and of the intersection of a sequence of sets gives

$$\bigcup_{n=1}^{\infty} A_n = \bigcup \mathrm{ran}(s), \tag{4.323}$$

$$\bigcap_{n=1}^{\infty} A_n = \bigcap \mathrm{ran}(s), \tag{4.324}$$

so that substitution yields

$$\bigcup_{n=1}^{\infty} A_n = \sup \mathrm{ran}(s), \tag{4.325}$$

$$\bigcap_{n=1}^{\infty} A_n = \sup \mathrm{ran}(s), \tag{4.326}$$

Now, if the sequence s is isotone, we obtain with (4.325) in view of Definition 4.6(1) the equation $\bigcup_{n=1}^{\infty} A_n = \lim_{n\to\infty} A_n$. Similarly, if s is antitone, we obtain because of (4.326) the equation $\bigcap_{n=1}^{\infty} A_n = \lim_{n\to\infty} A_n$ by applying Definition 4.6(2). Thus, the proposed equations (4.319) and (4.320) are true, and since Ω and s were initially arbitrary sets, we may therefore conclude that the proposed sentence holds, as claimed. □

Proposition 4.73. *For any set Ω, for any subset $\mathcal{K} \subseteq \mathcal{P}(\Omega)$, for any sequence of sets $s = (A_n)_{n\in\mathbb{N}_+}$ in $\mathcal{K}$ which is isotone with respect to the the reflexive partial ordering of inclusion $\subseteq_{\mathcal{K}}$, and for any $L \in \mathcal{K}$, it is true that L is the limit of $(A_n)_{n\in\mathbb{N}_+}$ with respect to $\subseteq_{\mathcal{K}}$ on $\mathcal{K}$ iff L is the limit of $(A_n)_{n\in\mathbb{N}_+}$ with respect to the reflexive partial ordering of inclusion $\subseteq_{\mathcal{P}(\Omega)}$, i.e.*

$$L = \overset{\subseteq_{\mathcal{K}}}{\lim_{n\to\infty}} A_n \;\Leftrightarrow\; L = \overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n. \tag{4.327}$$

Proof. We take arbitrary sets Ω, $\mathcal{K}$, s and L, we assume that $\mathcal{K}$ is included in the power set of Ω, we assume $s = (A_n)_{n\in\mathbb{N}_+}$ to be a sequence of sets in $\mathcal{K}$ such that it is isotone with respect to $\subseteq_{\mathcal{K}}$, and we assume that L is a set in $\mathcal{K}$. Observing here that $\mathcal{K}$ is a codomain of the sequence s, so that the inclusions

$$\mathrm{ran}(s) \subseteq \mathcal{K} \subseteq \mathcal{P}(\Omega) \tag{4.328}$$

hold with the definition of a codomain and the first assumption made, we obtain $\mathrm{ran}(s) \subseteq \mathcal{P}(\Omega)$ with (2.13), which shows that $\mathcal{P}(\Omega)$ is also a codomain of the sequence; thus, $s = (A_n)_{n\in\mathbb{N}_+}$ is a sequence both in $\mathcal{K}$ and in $\mathcal{P}(\Omega)$. We now see in light of the Monotony Criteria for sequences of sets and Note 4.13 that the isotony of $(A_n)_{n\in\mathbb{N}_+}$ with respect to $\subseteq_{\mathcal{K}}$ implies the truth of the universal sentence $\forall n\,(n \in \mathbb{N}_+ \Rightarrow A_n \subseteq A_{n^+})$, which in turn implies the isotony of $(A_n)_{n\in\mathbb{N}_+}$ (viewed now as a sequence in $\mathcal{P}(\Omega)$) with respect to $\subseteq_{\mathcal{P}(\Omega)}$. Therefore, we obtain for the limit with respect to $\subseteq_{\mathcal{P}(\Omega)}$

$$\overset{\subseteq_{\mathcal{P}(\Omega)}}{\sup}\,\mathrm{ran}(s) = \overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n = \bigcup_{n=1}^{\infty} A_n = \bigcup \mathrm{ran}(s). \tag{4.329}$$

by using the definition of the limit of an increasing sequence, Corollary 4.72a), and the definition of the union of a sequence of sets.

We now establish the first part ('$\Rightarrow$') of the equivalence (4.327), assuming

$$L = \overset{\subseteq_{\mathcal{K}}}{\lim_{n\to\infty}} A_n \quad \left[\overset{\subseteq_{\mathcal{K}}}{\sup}\,\mathrm{ran}(s)\right] \tag{4.330}$$

to be true (using also the definition of the limit of an increasing sequence). Thus, the element $L \in \mathcal{K}$ is the supremum of $\mathrm{ran}(s)$ with respect to $\subseteq_{\mathcal{K}}$, which finding implies with the inclusions (4.328) because of Exercise 3.44b) the equation $L = \bigcup \mathrm{ran}(s)$. Applying now substitution based on the equations (4.329) yields now the desired consequent

$$L = \overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n. \tag{4.331}$$

To prove the second part ('$\Leftarrow$'), we assume conversely (4.331) to be true, which gives $L = \bigcup \mathrm{ran}(s)$ with (4.329). Since we assumed initially L to be in $\mathcal{K}$, we obtain via substitution $\bigcup \mathrm{ran}(s) \in \mathcal{K}$, and therefore Exercise 3.44b) gives

$$L = \overset{\subseteq_{\mathcal{K}}}{\sup}\,\mathrm{ran}(s).$$

Since $s = (A_n)_{n\in\mathbb{N}_+}$ is isotone in $\mathcal{K}$, we may therefore apply the definition of the limit of an increasing sequence to obtain for the limit with respect to $\subseteq_{\mathcal{K}}$

$$\overset{\subseteq_{\mathcal{K}}}{\lim_{n\to\infty}} A_n = \overset{\subseteq_{\mathcal{K}}}{\sup}\,\mathrm{ran}(s) \quad [= L].$$

Thus, the second part of the equivalence also holds. Because Ω, $\mathcal{K}$, s and L were initially arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Exercise 4.21. Show for any set Ω, for any subset $\mathcal{K} \subseteq \mathcal{P}(\Omega)$, for any sequence of sets $s = (A_n)_{n\in\mathbb{N}_+}$ in $\mathcal{K}$ which is antitone with respect to the reflexive partial ordering of inclusion $\subseteq_{\mathcal{K}}$, and for any $L \in \mathcal{K}$ that L is the limit of $(A_n)_{n\in\mathbb{N}_+}$ with respect to $\subseteq_{\mathcal{K}}$ on $\mathcal{K}$ iff L is the limit of $(A_n)_{n\in\mathbb{N}_+}$ with respect to the reflexive partial ordering of inclusion $\subseteq_{\mathcal{P}(\Omega)}$, i.e.

$$L = \overset{\subseteq_{\mathcal{K}}}{\lim_{n\to\infty}} A_n \Leftrightarrow L = \overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n. \tag{4.332}$$

Corollary 4.74. *The following implication holds for any set Ω, any subset $\mathcal{K} \subseteq \mathcal{P}(\Omega)$ and any sequence of sets $s = (A_n)_{n\in\mathbb{N}_+}$ in $\mathcal{K}$ which is isotone with respect to $\subseteq_{\mathcal{K}}$.*

$$\bigcup_{n=1}^{\infty} A_n \in \mathcal{K} \Rightarrow \overset{\subseteq_{\mathcal{K}}}{\lim_{n\to\infty}} A_n = \bigcup_{n=1}^{\infty} A_n. \tag{4.333}$$

Proof. Letting Ω, $\mathcal{K}$ and s be arbitrary sets, assuming $\mathcal{K} \subseteq \mathcal{P}(\Omega)$ to hold and $s = (A_n)_{n\in\mathbb{N}_+}$ to be a sequence of sets in $\mathcal{K}$ such that s is isotone with respect to $\subseteq_{\mathcal{K}}$, and assuming moreover

$$\bigcup_{n=1}^{\infty} A_n \in \mathcal{K} \tag{4.334}$$

to be true, we recall the truth of the equations (4.329), so that

$$\bigcup_{n=1}^{\infty} A_n = \overset{\subseteq_{\mathcal{P}(\Omega)}}{\lim_{n\to\infty}} A_n$$

holds. Due to the assumption (4.334), we then obtain with Proposition 4.73

$$\bigcup_{n=1}^{\infty} A_n = \overset{\subseteq_{\mathcal{K}}}{\lim_{n\to\infty}} A_n,$$

which proves the implication (4.333). Since Ω, $\mathcal{K}$ and s were initially arbitrary sets, we may therefore conclude that the proposed universal sentence is true. □

Exercise 4.22. Verify that the following implication holds for any set Ω, any subset $\mathcal{K} \subseteq \mathcal{P}(\Omega)$ and any sequence of sets $s = (A_n)_{n\in\mathbb{N}_+}$ in $\mathcal{K}$ which is isotone with respect to $\subseteq_{\mathcal{K}}$.

$$\bigcap_{n=1}^{\infty} \in \mathcal{K} \Rightarrow \lim_{n\to\infty}^{\subseteq_{\mathcal{K}}} A_n = \bigcap_{n=1}^{\infty} A_n. \tag{4.335}$$

One of the great benefits of complete lattices lies in the fact that a monotone sequence (in the set forming the complete lattice) always has a limit.

Proposition 4.75. *For any complete lattice $(Y, \leq_Y)$, it is true that any increasing sequence $(a_n)_{n\in\mathbb{N}_+}$ in Y converges increasingly.*

Proof. We let Y, $\leq_Y$ and s be arbitrary sets such that $(Y, \leq_Y)$ is a complete lattice and such that s is an increasing sequence $(a_n)_{n\in\mathbb{N}_+}$ in Y. Since the range of s is a subset of its codomain Y, the supremum $\bar{L} = \sup \mathrm{ran}(s)$ (with respect to $\leq_Y$) exists (in Y) by definition of a complete lattice. Then, the existence of an element L in Y satisfying $L = \sup \mathrm{ran}(s)$ implies that the increasing sequence $(a_n)_{n\in\mathbb{N}_+}$ in Y is increasingly convergent, by definition. As Y, $\leq_Y$ and s were arbitrary, we may therefore conclude that Part a) of the proposition is true. □

Exercise 4.23. Show for any complete lattice $(Y, \leq_Y)$ that any decreasing sequence $(a_n)_{n\in\mathbb{N}_+}$ in Y converges decreasingly.

Proposition 4.76. *For any partially ordered set $(Y, <_Y)$ and any element $c \in Y$, it is true that the constant sequence $g_c = (a_n)_{n\in\mathbb{N}_+} = (c)_{n\in\mathbb{N}_+}$ converges increasingly to c.*

Proof. We take arbitrary Y, $<_Y$ and c, assume $c \in Y$ to be true, and assume moreover that the ordered pair $(Y, <_Y)$ is partially ordered. Now, since $\mathbb{N}_+ \neq \emptyset$ is clearly true, it follows with Proposition 3.193 that the constant function $g_c : \mathbb{N}_+ \to \{c\}$ is a surjection, so that we have $\mathrm{ran}(g_c) = \{c\}$; thus, g_c constitutes a sequence $(a_n)_{n\in\mathbb{N}_+}$ in Y. Furthermore, Corollary 3.106 shows that $c = \sup\{c\}$ is true, so that we obtain $c = \sup \mathrm{ran}(g_c)$ via substitution. As the constant sequence g_c is increasing according to Proposition 3.256, recalling that the ordered pair $(\mathbb{N}_+, <_{\mathbb{N}_+})$ based on the standard linear ordering of $\mathbb{N}_+$ is a partially ordered set, we have that g_c converges increasingly to the limit c. Because Y, $<_Y$ and c are arbitrary, we may therefore conclude that the proposition holds, as claimed. □

Exercise 4.24. Show for any partially ordered set $(Y, <_Y)$ and any element $c \in Y$ that the constant sequence $g_c = (a_n)_{n\in\mathbb{N}_+} = (c)_{n\in\mathbb{N}_+}$ converges decreasingly to c.

(Hint: Proceed in analogy to the proof of Proposition 4.76, using Exercise 3.112.)

Proposition 4.77 (Characterization of the pointwise limit of an increasing sequence of functions). *For any sets X and Y, any reflexive partial ordering $\leq$ of Y, any increasing sequence $f = (f_n)_{n\in\mathbb{N}_+}$ of functions from X to Y and any function g from X to Y, it is true that g is the limit of the sequence $(f_n)_{n\in\mathbb{N}_+}$ iff $g(x)$ is the limit of the sequence $f^{(x)} = (f_n(x))_{n\in\mathbb{N}_+}$ for every x in X, i.e.*

$$g = \lim_{n\to\infty} f_n \;\Leftrightarrow\; \forall x\,(x \in X \Rightarrow g(x) = \lim_{n\to\infty} f_n(x)). \tag{4.336}$$

Proof. We let X, Y, $\leq$ and f be arbitrary sets, and we assume $(Y, \leq)$ to be partially ordered, $f = (f_n)_{n\in\mathbb{N}_+}$ to be an increasing sequence of functions from X to Y and g to be a function from X to Y. Consequently, we see in light of Proposition 4.70a) that the sequence $f^{(x)} = (f_n(x))_{n\in\mathbb{N}_+}$ is also increasing for any $x \in X$. Regarding the first part ('$\Rightarrow$') of the stated equivalence, we assume

$$g = \lim_{n\to\infty} f_n \quad [= \sup \operatorname{ran}(f) \text{ pointwise}]$$

and let $x \in X$ be arbitrary, so that we obtain the desired result

$$g(x) = \sup \operatorname{ran}(f^{(x)}) = \lim_{n\to\infty} f_n(x)$$

with Theorem 3.255a) and the definition of the limit applied to the increasing sequence $(f_n(x))_{n\in\mathbb{N}_+}$. To establish the second part ('$\Leftarrow$'), we now assume

$$\forall x\,(x \in X \Rightarrow g(x) = \lim_{n\to\infty} f_n(x) = \sup \operatorname{ran}(f),$$

which implies

$$g = \sup \operatorname{ran}(f) \text{ pointwise} = \lim_{n\to\infty} f_n$$

again with Theorem 3.255a). This completes the proof of the equivalence; since X, Y, $\leq$, f and g were initially arbitrary sets, we may therefore conclude that the proposition is true. □

Exercise 4.25 (Characterization of the pointwise limit of a decreasing sequence of functions). Show that the equivalence (4.336) holds also for any decreasing sequence $f = (f_n)_{n\in\mathbb{N}_+}$ of functions from X to Y (for any sets X and Y, any reflexive partial ordering $\leq$ of Y and any function g from X to Y).

Notation 4.5. We call the limit f of a monotone sequence $(f_n)_{n\in\mathbb{N}_+}$ of functions also the *pointwise limit* of that sequence. Then, we also say that $(f_n)_{n\in\mathbb{N}_+}$ *converges pointwise* to f, symbolically

$$f = \lim_{n\to\infty} f_n \text{ pointwise,} \tag{4.337}$$

Note 4.14. In case of a complete lattice of functions $(Y^X, \preceq)$ both the pointwise supremum and the pointwise infimum of the range of any sequence $(f_n)_{n\in\mathbb{N}_+}$ of functions in Y^X exists. Then, in case the sequence is monotone, the pointwise limit also exists.

Definition 4.7 (Subsequence). For any set Y and any sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y, we say that a sequence $f' = (a'_n)_{n\in\mathbb{N}}$ is a *subsequence* of $(a_n)_{n\in\mathbb{N}}$ iff f' is the composition of f and some strictly increasing sequence $g = (m_n)_{n\in\mathbb{N}}$ in $\mathbb{N}$, i.e. iff

$$\exists g\,(g \in \mathbb{N}^{\mathbb{N}} \wedge g \text{ is strictly increasing } \wedge f' = f \circ g). \tag{4.338}$$

Exercise 4.26. Show for any set Y, any sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y and any strictly increasing sequence $g = (m_n)_{n\in\mathbb{N}}$ in $\mathbb{N}$

a) that the composition of f and g exists as the sequence $f' = (a'_n)_{n\in\mathbb{N}} = (a_{m_n})_{n\in\mathbb{N}}$ in Y, i.e.

$$(f \circ g) : \mathbb{N} \to Y, \quad n \mapsto a'_n = a_{m_n}, \tag{4.339}$$

b) and that any term a'_n of the sequence f' occurs in the original sequence f at an index m_n greater than or equal to n, i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow n \leq_{\mathbb{N}} m_n). \tag{4.340}$$

(Hint: Concerning a), apply Proposition 3.178; concerning b), carry out a proof by mathematical induction and apply the Transitivity Formula for $\leq$ and $<$ as well as (4.157) within the induction step.)

Corollary 4.78. *For any set Y and any sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y, it is true that any subsequence of f is also a sequence in Y.*

Corollary 4.79. *Any sequence $f = (a_n)_{n\in\mathbb{N}}$ is a subsequence of itself.*

Proof. We let Y and f be arbitrary sets such that $f = (a_n)_{n\in\mathbb{N}}$ is a sequence in Y. Since the identity function $\mathrm{id}_{\mathbb{N}}$ is a strictly increasing sequence in $\mathbb{N}$ according to Corollary 4.68, and because $f = f \circ \mathrm{id}_{\mathbb{N}}$ holds according to (3.610), we see that f is a subsequence of f, by definition. □

Proposition 4.80. *For any partially ordered set $(Y, \leq_Y)$, any sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y, any subsequence $f' = (a'_n)_{n\in\mathbb{N}}$ of f and any element $a \in Y$, it is true that a is a lower bound for f' if a is a lower bound for f.*

Proof. We let Y, $\leq$, f, f' and a be arbitrary such that $(Y, \leq_Y)$ is partially ordered, such that $f = (a_n)_{n\in\mathbb{N}}$ is a sequence in Y and $f' = (a'_n)_{n\in\mathbb{N}}$ a subsequence of f, and such that a is an element of Y. Then, there exists by definition of a subsequence a particular strictly increasing sequence $\bar{g} = (\bar{m}_n)_{n\in\mathbb{N}}$ in $\mathbb{N}$ with $f' = f \circ \bar{g}$. Now, to prove the proposed implication directly, we assume that a is a lower bound for the sequence f, which means by definition that

$$\forall y\,(y \in \mathrm{ran}(f) \Rightarrow a \leq_Y y) \tag{4.341}$$

holds. To prove that f' is a also bounded from below by a, we show that a is a lower bound for the range of f', i.e. that

$$\forall y\,(y \in \mathrm{ran}(f') \Rightarrow a \leq_Y y) \tag{4.342}$$

is true. For this purpose, we let y be arbitrary and assume $y \in \mathrm{ran}(f')$ to be true. By definition of a range, there then exists a constant, say $\bar{n}$, such that $(\bar{n}, y) \in f'$ holds. Since f' is a function/sequence, we may write this as

$$f'(\bar{n}) = a'_{\bar{n}} = y. \tag{4.343}$$

Due to Exercise 4.26b), we then obtain

$$a'_{\bar{n}} = a_{\bar{m}_{\bar{n}}} \quad [= f(\bar{m}_{\bar{n}})], \tag{4.344}$$

so that $(\bar{m}_{\bar{n}}, a_{\bar{m}_{\bar{n}}}) \in f$ holds. Consequently, $a_{\bar{m}_{\bar{n}}} \in \mathrm{ran}(f)$ is true (using the definition of a range), which finding further implies $a \leq_Y a_{\bar{m}_{\bar{n}}}$ with (4.341), and therefore $a \leq_Y a'_{\bar{n}}$ with (4.344). This in turn implies the desired inequality $a \leq_Y y$ with (4.343), and since y is arbitrary, we may infer from this the truth of (4.342). This proves that $f' = (a'_n)_{n\in\mathbb{N}}$ is a (sub)sequence bounded from below by a. As Y, $\leq_Y$, f, f' and a were also arbitrary, we may now finally conclude that the proposition holds. □

Exercise 4.27. Show for any partially ordered set $(Y, \leq_Y)$, any sequence $f = (a_n)_{n\in\mathbb{N}}$ in Y, any subsequence $f' = (a'_n)_{n\in\mathbb{N}}$ of f and any $u \in Y$ that u is an upper bound for f' if u is an upper bound for f.

(Hint: Proceed in analogy to the proof of Proposition 4.82.)

Corollary 4.81. *For any partially ordered set $(Y, \leq_Y)$ it is true that any subsequence of any bounded sequence in Y is also bounded.*

Proof. Letting $(Y, \leq_Y)$ be an arbitrary partially ordered set, $f = (a_n)_{n\in\mathbb{N}}$ an arbitrary bounded sequence in Y and $f' = (a'_n)_{n\in\mathbb{N}}$ an arbitrary subsequence of f, we have by definition of a bounded function that f is both bounded from below and bounded from above. Accordingly, to prove that f' is a bounded sequence, we show that f' is both bounded from below and bounded from above. Since f is bounded from below, there exists a lower bound for f, say $\bar{a}$, and it follows then with Proposition 4.80 that the subsequence f' of f is also bounded from below (by $\bar{a}$). Furthermore, as f is bounded from above, there exists an upper bound for f, say $\bar{u}$, and it follows then with Exercise 4.27 that the subsequence f' is itself bounded from above (by $\bar{u}$). Since f' is both bounded from below and bounded from above, it therefore follows that f' is bounded. Since $(Y, \leq_Y)$, f and f' were arbitrary, we conclude that the corollary is true. □

Proposition 4.82. *For any partially ordered set $(Y, \leq_Y)$ it is true that any subsequence of any increasing sequence in Y is also increasing.*

Proof. We let Y and $\leq_Y$ be arbitrary such that $(Y, \leq_Y)$ is a partially ordered set, let f be arbitrary such that $f = (a_n)_{n\in\mathbb{N}}$ is an increasing sequence in Y, so that

$$\forall M, N\,([M, N \in \mathbb{N} \wedge M <_{\mathbb{N}} N] \Rightarrow a_M \leq_Y a_N) \tag{4.345}$$

holds by definition of an increasing function/sequence, and we let f' be arbitrary such that $f' = (a'_n)_{n\in\mathbb{N}}$ is a subsequence of f. To show that f' is increasing, we verify (using again the definition of an increasing function)

$$\forall M, N\,([M, N \in \mathbb{N} \wedge M <_{\mathbb{N}} N] \Rightarrow a'_M \leq_Y a'_N) \tag{4.346}$$

For this purpose, we let M and N be arbitrary in $\mathbb{N}$ such that $M <_{\mathbb{N}} N$ holds. Let us now observe in light of the definition of a subsequence that, since f' is a subsequence of f, there exists a strictly increasing sequence of indexes in $\mathbb{N}$, say $(\bar{m}_n)_{n\in\mathbb{N}}$, such that $a'_M = a_{\bar{m}_M}$ as well as $a'_N = a_{\bar{m}_N}$ holds. Since the index sequence is strictly increasing, the initial assumption $M <_{\mathbb{N}} N$ implies $\bar{m}_M <_{\mathbb{N}} \bar{m}_N$. Together with the fact that $\bar{m}_N, \bar{m}_M \in \mathbb{N}$, this implies $a_{\bar{m}_M} \leq_Y a_{\bar{m}_N}$ with (4.345), which inequality we may also write as $a'_M \leq_Y a'_N$ (applying substitution). This proves the implication in (4.346), and since M and N were arbitrary, we therefore conclude that (4.346) is true, which means that the (sub)sequence f' is increasing. As Y, $\leq_Y$, f and f' were also arbitrary, it then follows that the proposition holds, as claimed. □

Exercise 4.28. Prove for any partially ordered set $(Y, \leq_Y)$ that any subsequence of any increasing sequence in Y is decreasing.

(Hint: Proceed in analogy to the proof of Proposition 4.82.)

Corollary 4.83. *For any partially ordered set* $(Y, \leq_Y)$ *it is true that any subsequence of any monotone sequence in* Y *is monotone.*

Exercise 4.29. Verify that all of the sentences in the current Section 4.5 remain valid when $\mathbb{N}$ is replaced by $\mathbb{N}_+$.

4.6. Induction and Recursion Theorems Involving Initial Segments

We begin this section with a useful variant of the Recursion Theorem.

Theorem 4.84 (Recursion Theorem for initial segments). *The following sentences are true for any counting domain $(C, s, 0_C)$, any set A, any $n \in C$, any function $f : \{0_C, \ldots, n\} \times A \to A$, and any $a \in A$.*

a) For an arbitrary constant $\bar{a}$ satisfying $\bar{a} \notin A$, it is true that there exists a unique function

$$\bar{f} : C \times A \cup \{\bar{a}\} \to A \cup \{\bar{a}\}, \quad (n, b) \mapsto \begin{cases} f(n, b) & \text{if } (n, b) \in \mathrm{dom}(f), \\ \bar{a} & \text{if } (n, b) \notin \mathrm{dom}(f) \end{cases} \tag{4.347}$$

b) Then, there is a unique function $\bar{u} : C \to A \cup \{\bar{a}\}$ such that

$$(1) \;\; \bar{u}(0_C) \quad = a, \tag{4.348}$$

$$(2) \;\; \bar{u}(s(m)) = \bar{f}(m, \bar{u}(m)) \quad \text{for any } m \in C. \tag{4.349}$$

c) Moreover, for any argument $m \in C$ which is less than or equal to n, it is true that the corresponding value of $\bar{u}$ is in A, that is,

$$\forall m \, (m \in C \Rightarrow [m \leq_C s(n) \Rightarrow \bar{u}(m) \in A]). \tag{4.350}$$

d) Furthermore, the restriction $u = \bar{u} \restriction \{0_C, \ldots, s(n)\}$ is a function from $\{0_C, \ldots, s(n)\}$ to A with

$$(1) \;\; u(0_C) \;\; = a, \tag{4.351}$$

$$(2) \;\; u(s(i)) = f(i, u(i)) \quad \text{for any } i \in \{0_C, \ldots, n\}. \tag{4.352}$$

Proof. We let C, s, 0_C, A, n, f and a be arbitrary and assume $(C, s, 0_C)$ to be a counting domain, n to be an element of C, f to be a function from $\{0_C, \ldots, n\} \times A$ to A, and a to be an element of A.

Concerning a), we first verify the universal sentence

$$\forall x \, (x \in C \times A \cup \{\bar{a}\} \Rightarrow \exists! y \, ([x \in \{0_C, \ldots, n\} \times A \Rightarrow y = f(x)] \\ \wedge \; [x \notin \{0_C, \ldots, n\} \times A \Rightarrow y = \bar{a}])). \tag{4.353}$$

For this purpose, we let x be arbitrary, assume $x \in C \times A \cup \{\bar{a}\}$ to be true, and prove the existential part first. To do this, we consider the two cases $x \in \{0_C, \ldots, n\} \times A$ and $x \notin \{0_C, \ldots, n\} \times A$.

In the first case $x \in \{0_C, \ldots, n\} \times A$, it follows from the initial assumption $f : \{0_C, \ldots, n\} \times A \to A$ with the Function Criterion that there exists a unique element $\bar{y}$ in A such that $\bar{y} = f(x)$ holds. Thus, the implication

$$x \in \{0_C, \ldots, n\} \times A \ \Rightarrow \ \bar{y} = f(x) \tag{4.354}$$

is true; furthermore, as $x \notin \{0_C, \ldots, n\} \times A$ is clearly false in the present first case, the implication

$$x \notin \{0_C, \ldots, n\} \times A \ \Rightarrow \ \bar{y} = \bar{a} \tag{4.355}$$

(having a false antecedent) is also true, so that the existential part holds. To prove the uniqueness part, we let y and y' be arbitrary such that

$$\begin{aligned}&([x \in \{0_C, \ldots, n\} \times A \Rightarrow y = f(x)] \wedge [x \notin \{0_C, \ldots, n\} \times A \Rightarrow y = \bar{a}]) \\ &\wedge \ ([x \in \{0_C, \ldots, n\} \times A \Rightarrow y' = f(x)] \wedge [x \notin \{0_C, \ldots, n\} \times A \Rightarrow y' = \bar{a}])\end{aligned} \tag{4.356}$$

holds. The current case assumption implies in particular $y = f(x)$ and $y' = f(x)$, which equations then give $y = y'$, proving the uniqueness part. Thus, the uniquely existential sentence in (4.353) is true in the first case.

In the second case $x \notin \{0_C, \ldots, n\} \times A$, we observe in light of (1.109) that there exists the unique element $\bar{y}$ such that $\bar{y} = \bar{a}$ holds. Thus, the implication (4.355) is then true, and the implication (4.354) also holds since the antecedent $x \in \{0_C, \ldots, n\} \times A$ is false in current case. This proves the existential part, and to prove the uniqueness part, we let y and y' be arbitrary such that the multiple conjunction (4.356) is satisfied. The current case assumption then yields in particular $y = \bar{a}$ and $y' = \bar{a}$, so that we obtain $y = y'$, which proves the uniqueness part. Therefore, the uniquely existential sentence in (4.353) is true in any case. As x was arbitrary, it then follows with Theorem 3.160 that there exists a unique function $\bar{f}$ with domain $C \times A \cup \{\bar{a}\}$ satisfying

$$\begin{aligned}\forall x\, (x \in C \times A \cup \{\bar{a}\} \ \Rightarrow ([&x \in \{0_C, \ldots, n\} \times A \Rightarrow \bar{f}(x) = f(x)] \\ &\wedge \ [x \notin \{0_C, \ldots, n\} \times A \Rightarrow \bar{f}(x) = \bar{a}])),\end{aligned} \tag{4.357}$$

which mapping we may also write as

$$x = (n, b) \mapsto \bar{f}(x) = \bar{f}(n, b) = \begin{cases} f(n, b) & \text{if } (n, b) \in \mathrm{dom}(f), \\ \bar{a} & \text{if } (n, b) \notin \mathrm{dom}(f) \end{cases} \tag{4.358}$$

It remains for us to verify that $A \cup \{\bar{a}\}$ is a codomain of $\bar{f}$, i.e. that $\mathrm{ran}(\bar{f}) \subseteq A \cup \{\bar{a}\}$ holds. For this purpose, we prove the equivalent (using the definition of a subset)

$$\forall y\, (y \in \mathrm{ran}(\bar{f}) \Rightarrow y \in A \cup \{\bar{a}\}). \tag{4.359}$$

Letting y be arbitrary and assuming $y \in \mathrm{ran}(\bar{f})$ to be true, we then see that there exists (by definition of a range) a constant, say $\bar{x}$, such that $(\bar{x}, y) \in \bar{f}$, which we may also write as $y = \bar{f}(\bar{x})$. We now use the fact that the disjunction $\bar{x} \in \mathrm{dom}(f) \vee \bar{x} \notin \mathrm{dom}(f)$ is true according to the Law of the Excluded Middle to prove the sentence

$$\bar{f}(\bar{x}) \in A \cup \{\bar{a}\} \tag{4.360}$$

by cases. On the one hand, if $\bar{x} \in \mathrm{dom}(f)$ is true, then (4.358) yields the equation $\bar{f}(\bar{x}) = f(\bar{x})$. Thus, $\bar{f}(\bar{x})$ is (according to the Function Criterion) an element of the codomain A of f, and this finding $\bar{f}(\bar{x}) \in A$ further implies (4.360) by definition of the union of two sets.

On the other hand, if $\bar{x} \notin \mathrm{dom}(f)$ is true, then (4.358) gives $\bar{f}(\bar{x}) = \bar{a}$, which implies and $\bar{f}(\bar{x}) \in \{\bar{a}\}$ with (2.169), and then (4.360), using again the definition of the union of two sets.

Thus, the proof by cases is complete, and (4.360) in turn proves the implication in (4.359). Since y is arbitrary, we may therefore conclude that the universal sentence (4.359) is true, so that the inclusion $\mathrm{ran}(\bar{f}) \subseteq A \cup \{\bar{a}\}$ holds indeed. Thus, the set $A \cup \{\bar{a}\}$ is a codomain of the function $\bar{f}$, so that the proof of a) is complete.

Concerning b), we observe that the element $a \in A$ is also in $\bar{A} = A \cup \{\bar{a}\}$, so that we may apply the Recursion Theorem to define $\bar{u}$ in (4.348) – (4.349) by using the function $\bar{f} : C \times \bar{A} \to \bar{A}$.

Concerning c), we apply a proof by mathematical induction. Regarding the base case ($m = 0_C$), we prove

$$0_C \leq_C s(n) \;\Rightarrow\; \bar{u}(0_C) \in A \tag{4.361}$$

On the one hand, we see that the initially assumed $n \in C$ implies

$$0_C \leq_C n <_C s(n)$$

with (4.184) and (4.142), and therefore $0_C <_C s(n)$ with the Transitivity Formula for $\leq$ and $<$. Then, the disjunction $0_C <_C s(n) \vee 0_C = s(n)$ is also true, which in turn implies $0_C \leq_C s(n)$ with the Characterization of induced irreflexive partial orderings. On the other hand, we have $\bar{u}(0_C) = a$ $(\in A)$ with (4.348) and the initial assumption $a \in A$, so that $\bar{u}(0_C) \in A$ holds. Thus, the antecedent and the consequent of the implication (4.361) are true, so that the implication itself is true in the base case.

Regarding the induction step, we let m be arbitrary in C, make the induction assumption

$$m \leq_C s(n) \;\Rightarrow\; \bar{u}(m) \in A, \tag{4.362}$$

and show that this implies

$$s(m) \leq_C s(n) \;\Rightarrow\; \bar{u}(s(m)) \in A. \tag{4.363}$$

We now prove the latter implication directly, assuming $s(m) \leq_C s(n)$ to be true. Since $m \in C$ implies $m <_C s(m)$ with (4.142), we obtain $m <_C s(n)$ with the Transitivity Formula for $<$ and $\leq$. Then, the disjunction $m <_C s(n) \lor m = s(n)$ also holds, which implies $m \leq_C s(n)$ with the Characterization of induced irreflexive partial orderings. Now, the preceding inequality gives $\bar{u}(m) \in A$ with the induction assumption (4.362). Furthermore, the assumed $s(m) \leq_C s(n)$ implies $m \leq_C n$ with (4.158) and then $m \in \{0_C, \ldots, n\}$ with the Characterization of initial segments. Thus, the two preceding findings $m \in \{0_C, \ldots, n\}$ and $\bar{u}(m) \in A$ yield

$$(m, \bar{u}(m)) \in \{0_C, \ldots, n\} \times A \quad [= \mathrm{dom}(f)]$$

with the definition of the Cartesian product of two sets (and the initial assumption for f), that is, $(m, \bar{u}(m)) \in \mathrm{dom}(f)$. Therefore, we obtain

$$\begin{aligned} \bar{u}(s(m)) &= \bar{f}(m, \bar{u}(m)) \\ &= f(m, \bar{u}(m)) \quad [\in A] \end{aligned}$$

with (4.349), (4.347), and the initial assumption that A is a codomain of f. These equations give $\bar{u}(s(m)) \in A$, which proves (4.363). As m is arbitrary, we may therefore conclude that the induction step is also true, so that the proof of (4.350) via mathematical induction is complete.

Concerning d), we first notice that the restriction $u = \bar{u} \restriction \{0_C, \ldots, s(n)\}$ is a function from $\{0_C, \ldots, s(n)\}$ to $A \cup \{\bar{a}\}$ in view of Proposition 3.164. Furthermore, we obtain

$$\begin{aligned} u(0_C) &= (\bar{u} \restriction \{0_C, \ldots, s(n)\})(0_C) \\ &= \bar{u}(0_C) \\ &= a \end{aligned}$$

with the preceding notation for u, the definition of a restriction, and (4.348), which proves (4.351). To verify (4.352), we let $i \in \{0_C, \ldots, n\}$ be arbitrary, so that we obtain $i \leq_C n$ with the Characterization of initial segments, which in turn implies $s(i) \leq_C s(n)$ with (4.162), and this inequality yields $s(i) \in \{0_C, \ldots, s(n)\}$ [$= \mathrm{dom}(u)$] again with the Characterization of initial segments; thus, $s(i) \in \mathrm{dom}(u)$ holds. We then obtain the equations

$$\begin{aligned} u(s(i)) &= \bar{u} \restriction \{0_C, \ldots, s(n)\})(s(i)) \\ &= \bar{u}(s(i)) \\ &= \bar{f}(i, \bar{u}(i)) \end{aligned} \tag{4.364}$$

using the notation for u, the definition of a restriction, and (4.349). Let us now observe that the previously established inequalities $i \leq_C n$ and $n <_C s(n)$ imply with the Transitivity Formula for $\leq$ and $<$ the truth of $i <_C s(n)$, which inequality then yields $\bar{u}(i) \in A$ with (4.350) as well as $i \in \{0_C, \ldots, s(n)\}$ with the Characterization of initial segments. Consequently, we obtain the equations

$$\begin{aligned} u(s(i)) &= \bar{f}(i, \bar{u}(i)) \\ &= f(i, \bar{u}(i)) \\ &= f(i, \bar{u} \upharpoonright \{0_C, \ldots, s(n)\}(i)) \\ &= f(i, u(i)) \end{aligned}$$

with (4.364), (4.347) in connection with the fact that $i \in \{0_C, \ldots, n\}$ and $\bar{u}(i) \in A$ evidently give $(i, \bar{u}(i)) \in \mathrm{dom}(f)$, then the definition of a restriction in connection with the the previously found $i \in \{0_C, \ldots, s(n)\}$, and finally the notation for u. We thus showed that $u(s(i)) = f(i, u(i))$ is true, and since i is arbitrary, we may therefore conclude that (4.352) also holds. These findings will also show that A is a codomain of u, i.e. that the range of u is included in A. To establish $\mathrm{ran}(u) \subseteq A$, we may apply the definition of a subset and prove equivalently

$$\forall y \, (y \in \mathrm{ran}(u) \Rightarrow y \in A). \tag{4.365}$$

Letting y be arbitrary and assuming $y \in \mathrm{ran}(u)$ to be true, there exists (by definition of a range) a constant, say $\bar{m}$, such that $(\bar{m}, y) \in u$ holds. Thus, $\bar{m}$ is an element of the domain $\{0_C, \ldots, s(n)\}$ of u, so that $\bar{m} \leq_C s(n)$ follows to be true with the Characterization of initial segments, and this inequality yields $\bar{u}(\bar{m}) \in A$ with (4.350). Furthermore, we may write $(\bar{m}, y) \in u$ on the one hand as $y = u(\bar{m})$, and on the other hand as $(\bar{m}, y) \in \bar{u} \upharpoonright \{0_C, \ldots, s(n)\}$ $[= u]$. The latter implies $(\bar{m}, y) \in \bar{u}$ with the definition of a restriction, which we may then also write as $y = \bar{u}(\bar{m})$. Combining the previous two equations for y via substitution, we obtain $u(\bar{m}) = \bar{u}(\bar{m})$, so that the previously established $\bar{u}(\bar{m}) \in A$ gives $[y =]\, u(\bar{m}) \in A$, and thus the desired $y \in A$. Since y is arbitrary, we may therefore conclude that the universal sentence (4.365), from which we infer with the definition of a subset that the range of u is indeed included in A. Thus, A is a codomain of u, which finding completes the proof of d).

Since C, s, 0_C, A, n, f and a were initially arbitrary in the proofs of a) – d), we may finally conclude that the stated theorem is true. □

Note 4.15. For any counting domain $(C, s, 0_C)$, any set A, any $n \in C$, any function $f : \{0_C, \ldots, n\} \times A \to A$ and any $a \in A$, it is true that there exists a unique function $u : \{0, \ldots, n^+\} \to A$ satisfying (4.351) and (4.352).

Before we restate this note for the particular counting domains $(\mathbb{N}, s^+, 0)$ and $(\mathbb{N}_+, s^+ \restriction \mathbb{N}_+, 1)$, we introduce the following alternative definitions of a sequence.

Definition 4.8 (Sequence on an initial segment of $\mathbb{N}$ & $\mathbb{N}_+$). We say that a family $(a_i \,|\, i \in I)$ is a sequence if

- $I = \{0, \ldots, n\}$ or
- $I = \{1, \ldots, n\}$

holds for some $n \in \mathbb{N}$.

Note 4.16. Since every initial segment $\{0, \ldots, m\}$ is identical with the natural number m^+ according to (4.92), it makes sense to speak of a sequence also in case of

- $I = n$,

where the natural number $n = 0 = \emptyset$ represents the empty index set, and where $n \neq 0$ represents (according to the Characterization of the elements of a counting set) the successor $n = m^+$ of some natural number m defining the initial segment $\{0, \ldots, m\}$.

We give here a first simple example of a sequence on an initial segment.

Proposition 4.85. *It is true for any set Y and any constants $y_1, y_2 \in Y$ that there exists a unique sequence $s = (a_i \,|\, i \in \{1, 2\})$ in Y with terms $a_1 = y_1$ and $a_2 = y_2$.*

Proof. We let Y, y_1 and y_2 be arbitrary and assume $y_1, y_2 \in Y$ to be true. According to Corollary 3.156, the singletons $\{(1, y_1)\}$ and $\{(2, y_2)\}$ are functions with domains $\{1\}$ and $\{2\}$, respectively. Since $1 \neq 2$ is true according to (4.167), we obtain now $\{1\} \cap \{2\} = \emptyset$ with (2.174), so that $\{(1, y_1)\}$ and $\{(2, y_2)\}$ are compatible functions because of Exercise 3.73. Consequently, the pair formed by $\{(1, y_1)\}$ and $\{(2, y_2)\}$ constitutes a compatible set of functions due to Proposition 3.174. We then obtain for its union

$$s = \bigcup\{\{(1, y_1)\}, \{(2, y_2)\}\} = \{(1, y_1)\} \cup \{(2, y_2)\} = \{(1, y_1), (2, y_2)\} \tag{4.366}$$

using (2.209) and (2.226), which constitutes a function with domain

$$\mathrm{dom}(s) = \bigcup\{\{1\}, \{2\}\} = \{1\} \cup \{2\} = \{1, 2\} = \{1, \ldots, 2\}$$

according to Theorem 3.175, (2.209), (2.226) and (4.242). Thus, we may write s as a sequence $(a_i \,|\, i \in \{1, 2\})$ with terms $a_i = s(i)$ for all $i \in \{1, 2\}$.

Observing in light of (2.151) and (4.366) that $(1, y_1) \in s$ and $(2, y_2) \in s$ are true, we obtain for the terms of s $y_1 = s_1$ $[= a_1]$ and $y_2 = s_2$ $[= a_2]$. It now remains for us to prove that s is a sequence in Y, i.e. that $\mathrm{ran}(s) \subseteq Y$ holds. For this purpose, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall y \, (y \in \mathrm{ran}(s) \Rightarrow y \in Y), \tag{4.367}$$

letting y be arbitrary and assuming $y \in \mathrm{ran}(s)$ to be true. Consequently, there is by definition of a range a constant $\bar{i}$ with $(\bar{i}, y) \in s$. This finding gives $y = s_{\bar{i}}$ (using sequence notation) as well as $\bar{i} \in \{1, 2\}$ $[= \mathrm{dom}(s)]$ (by definition of a domain). The latter yields the true disjunction $\bar{i} = 1 \vee \bar{i} = 2$ with the definition of a pair, which we use to prove $y \in Y$ by cases. The first case $\bar{i} = 1$ yields $y = s_1 = y_1$ $[\in Y]$, and the second case $\bar{i} = 2$ implies $y = s_2 = y_2$ $[\in Y]$. Thus, $y \in Y$ holds in any case. Since y was arbitrary, we may therefore conclude that the universal sentence (4.367) is true, so that the inclusion $\mathrm{ran}(s) \subseteq Y$ follows to be true (by definition of a subset). Thus, s is indeed a sequence in Y (by definition of a codomain), having the terms $a_1 = y_1$ and $a_2 = y_2$. Because Y, y_1 and y_2 were initially arbitrary, we may infer from this the truth of the proposition. □

Proposition 4.86. *For any set Y there exists a unique set $Y^{<\mathbb{N}}$ containing precisely every sequence in Y whose domain is some natural number.*

Proof. Letting Y be an arbitrary set, we may apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true uniquely existential sentence

$$\exists! Y^{<\mathbb{N}} \forall f \, (f \in Y^{<\mathbb{N}} \Leftrightarrow f \in \mathcal{P}(\mathbb{N} \times Y) \wedge \exists n \, (n \in \mathbb{N} \wedge f \in Y^n)).$$

Thus, the set $Y^{<\mathbb{N}}$ satisfies

$$\forall f \, (f \in Y^{<\mathbb{N}} \Leftrightarrow [f \in \mathcal{P}(\mathbb{N} \times Y) \wedge \exists n \, (n \in \mathbb{N} \wedge f \in Y^n)]). \tag{4.368}$$

We may now show that

$$\forall f \, (f \in Y^{<\mathbb{N}} \Leftrightarrow \exists n \, (n \in \mathbb{N} \wedge f \in Y^n)) \tag{4.369}$$

also holds. Letting f be arbitrary we notice that assuming $f \in Y^{<\mathbb{N}}$ implies with (4.368) in particular the existential sentence on the right-hand side of the equivalence, so that the first part ('$\Rightarrow$') of the equivalence holds. Conversely, assuming now that existential sentence to be true, there exists a natural number, say $\bar{n}$, with $f \in Y^{\bar{n}}$. Thus, f is the function $f : \bar{n} \to Y$, and f therefore is a subset of the Cartesian product $\bar{n} \times Y$ according to

Proposition 3.146. Since $\bar{n} \subseteq \mathbb{N}$ and $Y \subseteq Y$ are true because of (2.320) and (2.10), respectively, we then obtain $\bar{n} \times Y \subseteq \mathbb{N} \times Y$ with Proposition 3.8. Together with $f \subseteq \bar{n} \times Y$, this inclusion implies $f \subseteq \mathbb{N} \times Y$ with the transitivity of $\subseteq$ (in the sense of Proposition 2.5). Consequently, $f \in \mathcal{P}(\mathbb{N} \times Y)$ holds by definition of a power set, and the conjunction of this and the assumed existential sentence further implies $f \in Y^{<\mathbb{N}}$ with (4.368). This proves the second part ('$\Leftarrow$') of the equivalence in (4.369), and since f was arbitrary, we may therefore conclude that the universal sentence (4.369) is true. Thus, $Y^{<\mathbb{N}}$ containing precisely any sequence $f : n \to Y$ where n is some natural number. As Y was initially arbitrary, we thus see that the proposed sentence is true. □

Notation 4.6. For any natural numbers k and n with $k \leq n$ and

- for any sequence $s = (a_i \,|\, i \in \{0, \ldots, n\})$, we will write
$$(a_i \,|\, i \in \{0, \ldots, k\}) = s \upharpoonright \{0, \ldots, k\}. \tag{4.370}$$
- for any sequence $s = (a_i \,|\, i \in \{1, \ldots, n\})$, we will write
$$(a_i \,|\, i \in \{1, \ldots, k\}) = s \upharpoonright \{1, \ldots, k\}. \tag{4.371}$$

Then preceding notations immediately result in the following inclusions by means of Corollary 3.23 and Proposition 3.34.

Corollary 4.87. *For any natural numbers k and n with $k \leq n$ and*

a) for any sequence $s = (a_i \,|\, i \in \{0, \ldots, n\})$, it is true that
$$(a_i \,|\, i \in \{0, \ldots, k\}) \subseteq (a_i \,|\, i \in \{0, \ldots, n\}), \tag{4.372}$$
$$\mathrm{ran}((a_i \,|\, i \in \{0, \ldots, k\})) \subseteq \mathrm{ran}((a_i \,|\, i \in \{0, \ldots, n\})). \tag{4.373}$$

b) for any sequence $s = (a_i \,|\, i \in \{1, \ldots, n\})$, it is true that
$$(a_i \,|\, i \in \{1, \ldots, k\}) \subseteq (a_i \,|\, i \in \{1, \ldots, n\}), \tag{4.374}$$
$$\mathrm{ran}((a_i \,|\, i \in \{1, \ldots, k\})) \subseteq \mathrm{ran}((a_i \,|\, i \in \{1, \ldots, n\})). \tag{4.375}$$

Notation 4.7. For any $n \in \mathbb{N}$ we will write for the *union of a sequence of sets* $s = (A_i \,|\, i \in \{0, \ldots, n\})$ and $s = (A_i \,|\, i \in \{1, \ldots, n\})$, respectively,
$$\bigcup_{i=0}^{n} A_i, \tag{4.376}$$
$$\bigcup_{i=1}^{n} A_i. \tag{4.377}$$

Similarly, we write for the *intersection of a sequence of sets s*, respectively,

$$\bigcap_{i=0}^{n} A_i, \tag{4.378}$$

$$\bigcap_{i=1}^{n} A_i. \tag{4.379}$$

In the same way we denote the *Cartesian product of a sequence of sets s*, respectively, by

$$\bigtimes_{i=0}^{n} A_i, \tag{4.380}$$

$$\bigtimes_{i=1}^{n} A_i. \tag{4.381}$$

Here, we call every element of $\bigtimes_{i=1}^{n} A_i$ an *n-tuple*, symbolically

$$(a_1, \ldots, a_n), \tag{4.382}$$

or an *n-vector* symbolized by

$$\begin{pmatrix} a_1 \\ \vdots \\ a_n \end{pmatrix}. \tag{4.383}$$

In case of the *Cartesian product of a constant sequence of sets s* on $\{1, \ldots, n\}$ with value A, we also use the notation

$$\bigtimes_{i=1}^{n} A = A^n \tag{4.384}$$

and speak then of the n-th Cartesian power of A.

The following proposition shows that Cartesian powers constitute relatively simply structured sets of functions.

Proposition 4.88. *It is true for any natural number n that the n-th Cartesian power of a set A is identical with the set of functions from the initial segment of $\mathbb{N}_+$ up to n to A, that is,*

$$\forall n, A\,(n \in \mathbb{N} \Rightarrow A^n = A^{\{1,\ldots,n\}}). \tag{4.385}$$

Proof. We take an arbitrary natural number n and an arbitrary set A, and we prove the equation by means of the Equality Criterion for sets. For this purpose, we prove the universal sentence

$$\forall s\,(s \in A^n \Leftrightarrow s \in A^{\{1,\ldots,n\}}), \tag{4.386}$$

letting s be arbitrary. To prove the first part ('$\Rightarrow$') of the equivalence, we assume $s \in A^n$, which shows in light of (4.384) and the definition of the Cartesian product of a family of sets that s is a family with index set $\{1,\ldots,n\}$ and terms satisfying

$$\forall i\,(i \in \{1,\ldots,n\} \Rightarrow s_i \in A). \tag{4.387}$$

Thus, s is a function with domain $\{1,\ldots,n\}$, and we can also show that A is a codomain of s, i.e. that the inclusion $\mathrm{ran}(s) \subseteq A$ holds. To do this, we apply the definition of a subset and verify the equivalent universal sentence

$$\forall y\,(y \in \mathrm{ran}(s) \Rightarrow y \in A). \tag{4.388}$$

We take an arbitrary set y and assume that $y \in \mathrm{ran}(s)$ holds. The definition of a range gives us then a particular constant $\bar{k}$ satisfying $(\bar{k}, y) \in s$, which we can write in function/family notation as $y = s_{\bar{k}}$. Furthermore, $(\bar{k}, y) \in s$ implies with the definition of a domain $\bar{k} \in \{1,\ldots,n\}$, and this further implies $s_{\bar{k}} \in A$ with (4.387). Applying now substitution based on the preceding equation results in $y \in A$, which is the desired consequent of the implication in (4.388). Since y is arbitrary, we may therefore conclude that the universal sentence (4.388) holds, so that the equivalent inclusion $\mathrm{ran}(s) \subseteq A$ is indeed true. This means that A is a codomain of the function s (with domain $\{1,\ldots,n\}$), so that s turns out to be an element of the set of functions $A^{\{1,\ldots,n\}}$, as desired.

Regarding the second part ('$\Leftarrow$') of the equivalence in (4.386), we assume now $s \in A^{\{1,\ldots,n\}}$ to be true, so that s is a function with domain $\{1,\ldots,n\}$ and codomain A. Thus, we may view s as a family with index set $\{1,\ldots,n\}$. In addition, we see that s satisfies (4.387), since letting i be arbitrary and assuming i to be an element of the domain $\{1,\ldots,n\}$ of s implies with the Function Criterion that the uniquely existing function value s_i is in the codomain A of s; because i is arbitrary, (4.387) follows then indeed to be true. These findings demonstrate now in view of the definition of the Cartesian product of a family of sets and in view of the notation for Cartesian powers that $s \in A^n$ holds.

We thus proved the equivalence in (4.386), in which s was arbitrary, so that the universal sentence (4.386) follows to be true. This in turn completes the proof of the equation $A^n = A^{\{1,\ldots,n\}}$, and as n and A were initially both arbitrary, we conclude that the stated proposition holds. □

We now give a first useful application of Cartesian powers in the context of intervals.

Exercise 4.30. Define for any partially ordered set $(Y, \leq_Y)$, any $n \in \mathbb{N}$ and any n-tuples $a = (a_i \,|\, i \in \{1, \ldots, n\})$ and $b = (b_i \,|\, i \in \{1, \ldots, n\})$ in Y the n-tuples $([a_i, b_i]_Y \,|\, i \in \{1, \ldots, n\})$ and $((a_i, b_i)_Y \,|\, i \in \{1, \ldots, n\})$.

(Hint: Apply Function definition by replacement.)

Theorem 4.89 (Characterization of closed & open intervals in Y^n as Cartesian products of intervals in Y). *For any partially ordered set $(Y, \leq_Y)$ and any $n \in \mathbb{N}$, it is true that*

a) each closed interval in Y^n with respect to the reflexive partial ordering $\preceq$ of Y^n can be written as a Cartesian product of a family of closed intervals in Y, in the sense that

$$\forall a, b\,(a, b \in Y^n \Rightarrow [a, b]_{Y^n} = \bigtimes_{i=1}^{n} [a_i, b_i]_Y). \tag{4.389}$$

b) each open interval in Y^n with respect to the irreflexive partial ordering $\prec$ of Y^n (derived from the induced irreflexive partial ordering $<_Y$) can be written as a Cartesian product of a family of open intervals in Y, in the sense that

$$\forall a, b\,(a, b \in Y^n \Rightarrow (a, b)_{Y^n} = \bigtimes_{i=1}^{n} (a_i, b_i)_Y). \tag{4.390}$$

Proof. We let $(Y, \leq_Y)$ be an arbitrary partially ordered set (where $\leq_Y$ is reflexive) and n an arbitrary natural number. Then, the reflexive partial ordering $\preceq$ of $Y^n = Y^{1,\ldots,n}$ is defined through Proposition 3.251 (applying also Proposition 4.88. Letting now $a, b \in Y^n$ be arbitrary, we observe that these constants can be written as the families $a = (a_i \,|\, i \in \{1, \ldots, n\})$ and $b = (b_i \,|\, i \in \{1, \ldots, n\})$. Exercise 4.30 demonstrates that the n-tuple $([a_i, b_i]_Y \,|\, i \in \{1, \ldots, n\})$ is defined. We apply the Equality Criterion for sets to establish the stated equation and prove accordingly

$$\forall x\,(x \in [a, b]_{Y^n} \Leftrightarrow x \in \bigtimes_{i=1}^{n} [a_i, b_i]_Y). \tag{4.391}$$

We taking an arbitrary x. Regarding the first part ('$\Rightarrow$') of the equivalence, we assume $x \in [a, b]_{Y^n}$. The definition of a closed interval with respect to the reflexive partial ordering $\preceq$ of Y^n shows on the one hand that x is an element of Y^n, which may therefore be written as the family $x =$

$(x_i \,|\, i \in \{1, \ldots, n\})$. On the other hand, the inequalities $a \preceq x \preceq b$ hold. Consequently, the universal sentences

$$\forall i \,(i \in \{1, \ldots, n\} \Rightarrow a_i \leq_Y x_i), \tag{4.392}$$

$$\forall i \,(i \in \{1, \ldots, n\} \Rightarrow x_i \leq_Y b_i) \tag{4.393}$$

hold according to (3.903), which allow us to establish the truth of

$$\forall i \,(i \in \{1, \ldots, n\} \Rightarrow x_i \in [a_i, b_i]_Y). \tag{4.394}$$

Letting $i \in \{1, \ldots, n\}$ be arbitrary, we obtain from (4.392) and (4.393) the inequalities $a_i \leq_Y x_i \leq_Y b_i$. Therefore, $x_i \in [a_i, b_i]_Y$ holds by definition of a closed interval in Y, as desired. As i was arbitrary, we may infer from this the truth of the universal sentence (4.394). As x is a family with index set $\{1, \ldots, n\}$, we obtain $x \in \bigtimes_{i=1}^{n} [a_i, b_i]_Y$ due to (3.858), which completes the proof of the first part of the equivalence in (4.391).

To establish the second part ('$\Leftarrow$'), we assume now $x \in \bigtimes_{i=1}^{n} [a_i, b_i]_Y$ to be true. Clearly, this implies the truth of (4.394). For an arbitrary $i \in \{1, \ldots, n\}$, that universal sentence yields $x_i \in [a_i, b_i]_Y$, so that the inequalities $a_i \leq_Y x_i$ and $x_i \leq_Y b_i$ evidently hold. We may therefore conclude that the universal sentences (4.392) and (4.392) are both true. Clearly, these imply the inequalities $a \preceq x$ and $x \preceq b$ and therefore $x \in [a, b]_{Y^n}$, as desired. Thus, the proof of the equivalence is now complete, in which x is arbitrary, so that the universal sentence (4.391) also holds. Consequently, the sets $[a, b]_{Y^n}$ and $\bigtimes_{i=1}^{n} [a_i, b_i]_Y$ are identical. Since a and b were arbitrary, we may infer from the truth of this equation the truth of the universal sentence (4.389). As the sets $(Y, \leq_Y)$ and n were initially also arbitrary, we may now finally conclude that Part a) of the stated theorem is true. Part b) can be proved similarly. $\square$

Exercise 4.31. Establish the Characterization of open intervals in Y^n as Cartesian products of intervals in Y.

(Hint: Induce $<_Y$ from $\leq_Y$ and apply Note 3.14) regarding the irreflexive partial ordering $\prec$ defined as in Exercise 3.109.

Exercise 4.32. Show for any set Y that

a) there exists a unique set $Y^{<\mathbb{N}_+}$ containing precisely every sequence in Y whose domain is some initial segment of $\mathbb{N}_+$, in the sense that

$$\forall f \,(f \in Y^{<\mathbb{N}_+} \Leftrightarrow \exists n \,(n \in \mathbb{N} \,\wedge\, f \in Y^{\{1,\ldots,n\}})) \tag{4.395}$$

(Hint: Proceed in analogy to the proof of Proposition 4.86), using now the power set $\mathcal{P}(\mathbb{N}_+ \times Y)$ in connection with (4.240).)

b) there exists the unique sequence $(Y^n)_{n\in\mathbb{N}}$ of Cartesian powers of Y. (Hint: Use replacement in connection with (1.109).)

c) the set $Y^{<\mathbb{N}_+}$ is identical with the union of the sequence of Cartesian powers of Y, that is,

$$Y^{<\mathbb{N}_+} = \bigcup_{n=0}^{\infty} Y^n. \tag{4.396}$$

(Hint: Apply the Equality Criterion for sets in connection with (4.395), (4.385) and the Characterization of the union of a family of sets.)

d) the set $Y^{<\mathbb{N}_+}$ is identical with the singleton formed by the empty set if Y is itself empty, that is,

$$Y = \emptyset \Rightarrow Y^{<\mathbb{N}_+} = \{\emptyset\}. \tag{4.397}$$

(Hint: Apply the Equality Criterion for sets in connection with Proposition 3.152, (4.239), Proposition 3.151 and (2.169).)

Theorem 4.90 (Recursive evaluation of the union & intersection of a sequence of sets on an initial segment of $\mathbb{N}_+$). *The following equations hold for any $n \in \mathbb{N}$ and any sequence $A = (A_i \,|\, i \in \{1,\ldots,n^+\})$.*

$$\bigcup_{i=1}^{n^+} A_i = \left(\bigcup_{i=1}^{n} A_i\right) \cup A_{n^+}, \tag{4.398}$$

$$\bigcap_{i=1}^{n^+} A_i = \left(\bigcap_{i=1}^{n} A_i\right) \cap A_{n^+}. \tag{4.399}$$

Proof. We let n be an arbitrary natural number and A be an arbitrary set such that A is a sequence $(A_i \,|\, i \in \{1,\ldots,n^+\})$. We now establish the proposed equation (4.398) by applying the Equality Criterion for sets, i.e. by proving the universal sentence

$$\forall y\,(y \in \bigcup_{i=1}^{n^+} A_i \Leftrightarrow y \in \left(\bigcup_{i=1}^{n} A_i\right) \cup A_{n^+}). \tag{4.400}$$

For this purpose, we let y be arbitrary and assume first

$$y \in \bigcup_{i=1}^{n^+} A_i \tag{4.401}$$

to be true, which assumption implies the truth of the existential sentence

$$\exists i\,(i \in \{1,\ldots,n^+\} \,\wedge\, y \in A_i) \tag{4.402}$$

with the Characterization of the union of a family of sets. Thus, there is a particular $\bar{k} \in \{1,\ldots,n^+\}$ with $y \in A_{\bar{k}}$. We therefore obtain $\bar{k} \in \{1,\ldots,n\} \cup \{n^+\}$ with (4.241), which we may write also as the disjunction of $\bar{k} \in \{1,\ldots,n\}$ and $\bar{k} \in \{n^+\}$, according to the definition of the union of two sets. We now use this true disjunction to prove

$$y \in \bigcup_{i=1}^{n} A_i \,\vee\, y \in A_{n^+} \tag{4.403}$$

by cases. In the first case of $\bar{k} \in \{1,\ldots,n\}$, we see in light of the previously established $y \in A_{\bar{k}}$ that the existential sentence

$$\exists i\,(i \in \{1,\ldots,n\} \,\wedge\, y \in A_i) \tag{4.404}$$

is true. Since $\bar{k} \in \{1,\ldots,n\}$ implies that $A_{\bar{k}}$ is a term of the restricted sequence $(A_i \,|\, i \in \{1,\ldots,n\})$, the preceding existential sentence yields with the Characterization of the union of a family of sets

$$y \in \bigcup_{i=1}^{n} A_i, \tag{4.405}$$

so that the desired disjunction (4.403) holds indeed in the first case. The second case $\bar{k} \in \{n^+\}$ gives $\bar{k} = n^+$ with (2.169), and therefore $y \in A_{\bar{k}}$ implies $y \in A_{n^+}$ via substitution. Thus, the disjunction (4.403) holds also for the second case, and this disjunction yields now (by definition of the union of two sets)

$$y \in \left(\bigcup_{i=1}^{n} A_i\right) \cup A_{n^+}, \tag{4.406}$$

so that the first part ('$\Rightarrow$') of the equivalence in (4.400) holds.

To establish the second part ('$\Leftarrow$'), we now assume (4.406) to be true, which evidently gives the disjunction (4.403). Let us now apply this disjunction to prove (4.402) by cases. On the one hand, if $y \in \bigcup_{i=1}^{n} A_i$ holds, then the Characterization of the union of a family of sets implies the existence of a particular $\bar{k} \in \{1,\ldots,n\}$ with $y \in A_{\bar{k}}$. Because the inclusion

$$\{1,\ldots,n\} \subseteq \{1,\ldots,n\} \cup \{n^+\} \quad [= \{1,\ldots,n^+\}]$$

is true according to (2.245), we then obtain $\bar{k} \in \{1,\ldots,n^+\}$ by definition of a subset. In view of $y \in A_{\bar{k}}$, the existential sentence (4.402) is thus clearly true in the first case. On the other hand, if $y \in A_{n^+}$ holds, we see in light of the evident fact $n^+ \in \{n^+\}$ that the desired existential sentence is again true, so that the proof by cases is complete. Consequently, we obtain (4.401) with the Characterization of the union of a family of sets, which finding completes the proof of the equivalence.

As y was arbitrary, we may therefore conclude that the universal sentence (4.400) holds, so that the equation (4.398) follows to be true.

We now establish the proposed equation (4.399), applying again the Equality Criterion for sets, i.e. we prove the universal sentence

$$\forall y \, (y \in \bigcap_{i=1}^{n^+} A_i \Leftrightarrow y \in \left(\bigcap_{i=1}^{n} A_i\right) \cap A_{n^+}). \tag{4.407}$$

To do this, we take an arbitrary y and assume first

$$y \in \bigcap_{i=1}^{n^+} A_i \tag{4.408}$$

to be true, which assumption implies

$$\forall i \, (i \in \{1, \ldots, n^+\} \Rightarrow y \in A_i). \tag{4.409}$$

with the Characterization of the intersection of a family of sets. Let us observe now that the desired consequent is equivalent to

$$\forall i \, (i \in \{1, \ldots, n\} \Rightarrow y \in A_i) \, \wedge \, y \in A_{n^+} \tag{4.410}$$

in view of the the Characterization of the intersection of a family of sets and the definition of the intersection of two sets. To prove the first part of this conjunction, we let i be arbitrary, assume $i \in \{1, \ldots, n\}$ to be true, and show that $y \in A_i$ also holds. Since $\{1, \ldots, n\}$ is included in $\{1, \ldots, n^+\}$, the preceding assumption implies $i \in \{1, \ldots, n^+\}$ and therefore $y \in A_i$ with (4.409), as desired. As i was arbitrary, we may therefore conclude that the first part of the conjunction (4.410) holds. Regarding the second part, we observe the truth of $n^+ \in \{1, \ldots, n^+\}$, so that the desired $y \in A_{n^+}$ follows immediately to be true with (4.409). Thus, the first part of the equivalence to be proven holds.

Concerning the second part ('$\Leftarrow$'), we assume $y \in (\bigcap_{i=1}^{n} A_i) \cap A_{n^+}$ to be true, which gives the equivalent conjunction (4.410). We now show that the universal sentence (4.409) follows to be true, letting i be arbitrary and assuming

$$i \in \{1, \ldots, n^+\} \quad [= \{1, \ldots, n\} \cup \{n^+\}]$$

to hold. Consequently, the disjunction $i \in \{1, \ldots, n\} \vee i \in \{n^+\}$ holds, which we now use to prove (4.409) by cases. If $i \in \{1, \ldots, n\}$ is true, then the first part of the conjunction (4.410) gives $y \in A_i$, as required, and if $i \in \{n^+\}$ is true, so that $i = n^+$ holds, then we obtain again $y \in A_i$ via substitution from the second part of the conjunction. Thus, the proof by cases is complete, and since i is arbitrary, we may therefore conclude that the universal sentence (4.409) is true. This finding means that (4.408) holds, so that the equivalence (4.407) is true.

Because y is arbitrary, we may infer from this the truth of (4.407), which universal sentence implies the truth of the the equation (4.399). Because n and A were initially arbitrary, we may now further conclude that the stated theorem is indeed true. □

Exercise 4.33. Establish the following equations for any $n \in \mathbb{N}$ and any sequence $A = (A_i \,|\, i \in \{0, \ldots, n^+\})$.

$$\bigcup_{i=0}^{n^+} A_i = \left(\bigcup_{i=0}^{n} A_i \right) \cup A_{n^+}, \tag{4.411}$$

$$\bigcap_{i=0}^{n^+} A_i = \left(\bigcap_{i=0}^{n} A_i \right) \cap A_{n^+}. \tag{4.412}$$

Corollary 4.91. *For any set A, any $a \in A$, any $n \in \mathbb{N}$ and any function $f : \{0, \ldots, n\} \times A \to A$, it is true that there exists a unique sequence $u = (u_i \,|\, i \in \{0, \ldots, n^+\})$ in A satisfying*

$$(1) \quad u_0 \;= a, \tag{4.413}$$

$$(2) \quad u_{i^+} = f(i, u_i) \quad \text{for any } i \in \{0, \ldots, n\}. \tag{4.414}$$

Corollary 4.92. *For any set A, any $a \in A$, any $n \in \mathbb{N}_+$ and any function $f : \{1, \ldots, n\} \times A \to A$, it is true that there exists a unique sequence $u = (u_i \,|\, i \in \{1, \ldots, n^+\})$ in A satisfying*

$$(1) \quad u_1 \;= a, \tag{4.415}$$

$$(2) \quad u_{i^+} = f(i, u_i) \quad \text{for any } i \in \{1, \ldots, n\}. \tag{4.416}$$

We now introduce another technique for mathematical induction.

Proposition 4.93. *The following implication holds for an arbitrary formula $\varphi(n)$ and for any counting domain $(C, s, 0_C)$. If*

$$\forall n \, (n \in C \Rightarrow [\forall m \, ([m \in C \wedge m <_C n] \Rightarrow \varphi(m)) \Rightarrow \varphi(n)]) \tag{4.417}$$

is true, then the set $\{n : n \in C \wedge \varphi(n)\}$ of all $n \in C$ for which $\varphi(n)$ holds is inductive.

Proof. We let C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain and prove the stated implication directly, assuming (4.417) to be true. To show that the set $X = \{n : n \in C \wedge \varphi(n)\}$ (see (4.46) in Exercise 4.2a)) is inductive with respect to $(C, s, 0_C)$, we verify

$$0_C \in X \wedge \forall n\,(n \in X \Rightarrow s(n) \in X) \tag{4.418}$$

according to Note 4.3. To prove the first part of this conjunction, we observe that the fact $0_C \in C$ implies with the assumption (4.417) that

$$\forall m\,([m \in C \wedge m <_C 0_C] \Rightarrow \varphi(m)) \;\Rightarrow\; \varphi(0_C), \tag{4.419}$$

is true. We now verify that the antecedent (i.e., the universal sentence) is true, which will then imply the truth of $\varphi(0_C)$. Letting m be arbitrary, we have that $m \in C \wedge m <_C 0_C$ is false due to (4.186), so that the implication

$$[m \in C \wedge m <_C 0_C] \Rightarrow \varphi(m)$$

is true. As m was arbitrary, we may therefore conclude that the universal sentence in (4.419) holds, which then implies $\varphi(0_C)$ because the implication (4.419) is true. Consequently, the conjunction of $0_C \in C$ and $\varphi(0_C)$ implies the desired $0_C \in X$ by definition of X.

To verify the second part of the conjunction (4.418), we let $n \in X$ be arbitrary, which means that $n \in C$ and $\varphi(n)$ are both true by definition of X. Since the successor function s is a function from C to C, we see that $n \in C$ implies $s(n) \in C$, which further implies

$$\forall m\,([m \in C \wedge m <_C s(n)] \Rightarrow \varphi(m)) \Rightarrow \varphi(s(n)) \tag{4.420}$$

with the assumed antecedent (4.417). Furthermore, since $n \in C$ implies $n <_C s(n)$ according to (4.142), the conjunction $n \in C \wedge n <_C s(n)$ is true; since $\varphi(n)$ also holds, the implication

$$[n \in C \wedge n <_C s(n)] \;\Rightarrow\; \varphi(n) \tag{4.421}$$

is also true. Now, as the implication

$$[m \in C \wedge m <_C s(n)] \Rightarrow \varphi(m)) \;\Rightarrow\; \varphi(s(n))$$

in (4.420) is true for the particular constant $m = n$, we see that the truth of the antecedent (4.421) then implies the truth of $\varphi(s(n))$. Thus, the conjunction $s(n) \in C \wedge \varphi(s(n))$ is true, which in turn gives the desired $s(n) \in X$ (by definition of X). This completes the proof of the conjunction (4.418), so that the set $X = \{n : n \in C \wedge \varphi(n)\}$ is indeed inductive with respect to $(C, s, 0_C)$. Since C, s and 0_C were initially arbitrary, we may therefore conclude that the proposition is true. □

Corollary 4.94. *The following implication holds for an arbitrary formula $\varphi(n)$ and for any counting domain $(C, s, 0_C)$. If (4.417) is true, then $\varphi(n)$ holds for all $n \in C$.*

Proof. Letting $(C, s, 0_C)$ be an arbitrary counting domain, we assume that (4.417) is true, which then implies with Proposition 4.93 that the set $X = \{n : n \in C \land \varphi(n)\}$ is inductive with respect to $(C, s, 0_C)$. It then follows with Exercise 4.2b) that $\varphi(n)$ holds for all elements of C. □

Method 4.6 (Proof by strong induction for counting domains). To prove that a given formula $\varphi(n)$ holds for all elements of the counting set C in a counting domain $(C, s, 0_C)$, we may show that the *induction step* (4.417) is true.

Corollary 4.95. *The following implications hold for an arbitrary formula $\varphi(n)$.*

a) If

$$\forall n\, (n \in \mathbb{N} \Rightarrow [\forall m\, ([m \in \mathbb{N} \land m <_{\mathbb{N}} n] \Rightarrow \varphi(m)) \Rightarrow \varphi(n)]) \tag{4.422}$$

is true, then $\varphi(n)$ is true for all $n \in \mathbb{N}$.

b) If

$$\forall n\, (n \in \mathbb{N}_+ \Rightarrow [\forall m\, ([m \in \mathbb{N}_+ \land m <_{\mathbb{N}_+} n] \Rightarrow \varphi(m)) \Rightarrow \varphi(n)]) \tag{4.423}$$

is true, then $\varphi(n)$ is true for all $n \in \mathbb{N}_+$.

Method 4.7 (Proof by strong induction (for $\mathbb{N}$)). To prove that a given formula $\varphi(n)$ holds for all natural numbers, we may show that the induction step (4.422) is true.

Note 4.17. The assumption of a base case is not necessary since $\varphi(0)$ is implied by (4.422).

Method 4.8 (Proof by strong induction (for $\mathbb{N}_+$)). To prove that a given formula $\varphi(n)$ holds for all positive natural numbers, we may show that the induction step (4.423) is true.

Theorem 4.96 (Strong Recursion Theorem). *The following sentences are true for any set B and any function $F : B^{<\mathbb{N}} \to B$.*

a) There exists a unique function f with domain $\mathbb{N} \times B^{<\mathbb{N}}$ such that

$$x = (n, g) \mapsto \begin{cases} g \cup \{(n, F(g))\} & \text{if } \mathrm{dom}(g) = n \\ \emptyset & \text{if } \mathrm{dom}(g) \neq n \end{cases} \tag{4.424}$$

b) Then, there exists a unique sequence $u = (u_n)_{n\in\mathbb{N}}$ *in* $B^{<\mathbb{N}}$ *satisfying*

$$(1)\ \ u_0 \ = \emptyset, \tag{4.425}$$
$$(2)\ \ u_{n^+} = f(n, u_n) \quad \text{for any } n \in \mathbb{N}, \tag{4.426}$$

and any term u_n *is a sequence in* B *with domain* n*, i.e.*

$$\forall n\, (n \in \mathbb{N} \Rightarrow u_n \in B^n). \tag{4.427}$$

c) Furthermore, the sequence $u = (u_n)_{n\in\mathbb{N}}$ *is isotone, and its range is a compatible set of functions satisfying*

$$\forall u'\, (u' \in \operatorname{ran}(u) \Rightarrow \exists m\, (m \in \mathbb{N} \wedge u' = u_m \wedge u' \in B^m)). \tag{4.428}$$

d) Moreover, that range's union

$$v = \bigcup \operatorname{ran}(u) \tag{4.429}$$

is a sequence in B *with domain* $\mathbb{N}$*, and every term* u_n *of the sequence* $(u_n)_{n\in\mathbb{N}}$ *is identical with the restriction of* v *to* n*, i.e.*

$$\forall n\, (n \in \mathbb{N} \Rightarrow v \restriction n = u_n). \tag{4.430}$$

e) Finally, the sequence $v = (v_n)_{n\in\mathbb{N}}$ *satisfies*

$$\forall n\, (n \in \mathbb{N} \Rightarrow v_n = F(v \restriction n)), \tag{4.431}$$

and v *is the only sequence in* B *with domain* $\mathbb{N}$ *satisfying (4.431), i.e.*

$$\forall v'\, ([v' \in B^{\mathbb{N}} \wedge \forall n\, (n \in \mathbb{N} \Rightarrow v'_n = F(v \restriction n))] \Rightarrow v = v'). \tag{4.432}$$

Proof. We let B and F be arbitrary sets and assume that F is a function from $B^{<\mathbb{N}}$ to B.

Concerning a), we apply Function definition by replacement and prove for this purpose

$$\forall x\, (x \in \mathbb{N} \times B^{<\mathbb{N}} \Rightarrow \exists! y\, (\varphi(x, y))), \tag{4.433}$$

where $\varphi(x, y)$ is the formula

$$\begin{aligned} \exists n, g\, (x = (n, g) \ \wedge\ & [\operatorname{dom}(g) = n \ \Rightarrow\ y = g \cup \{(n, F(g))\}] \\ \wedge\ & [\operatorname{dom}(g) \neq n \ \Rightarrow\ y = \emptyset]). \end{aligned} \tag{4.434}$$

We let $\bar{x}$ be arbitrary in $\mathbb{N} \times B^{<\mathbb{N}}$, so that there exists (by definition of a Cartesian product) an element of $\mathbb{N}$, say $\bar{n}$, and an element of $B^{<\mathbb{N}}$, say $\bar{g}$, such that

$$\bar{x} = (\bar{n}, \bar{g}). \tag{4.435}$$

We now prove the existential part of $\exists! y\,(\varphi(\bar{x}, y))$. According to the Law of the Excluded Middle, the disjunction $\mathrm{dom}(\bar{g}) = \bar{n} \vee \mathrm{dom}(\bar{g}) \neq \bar{n}$ is true, which we now use to prove the sentence $\exists y\,(\varphi(\bar{x}, y))$ by cases. In the first case that $\mathrm{dom}(\bar{g}) = \bar{n}$ holds, we observe in light of (1.109) that there exists a (unique) set $\bar{y}$ such that the equation $\bar{y} = \bar{g} \cup \{(\bar{n}, F(\bar{g}))\}$ holds. Then, the implication

$$\mathrm{dom}(\bar{g}) = \bar{n} \;\Rightarrow\; \bar{y} = \bar{g} \cup \{(\bar{n}, F(\bar{g}))\} \tag{4.436}$$

is true because the antecedent and the consequent are both true. Furthermore, the current case assumption implies with the Double Negation Law that $\mathrm{dom}(\bar{g}) \neq \bar{n}$ is false, so that the implication

$$\mathrm{dom}(\bar{g}) \neq \bar{n} \;\Rightarrow\; \bar{y} = \emptyset \tag{4.437}$$

is true because of the false antecedent. Thus, the conjunction of (4.435), (4.436) and (4.437) is true, so that the formula (4.434) becomes a true existential sentence for $\bar{x}$ and $\bar{y}$. This means that $\varphi(\bar{x}, \bar{y})$ is true, which shows that the existential sentence $\exists y\,(\varphi(\bar{x}, y))$ holds (in the first case). In the second case that $\mathrm{dom}(\bar{g}) \neq \bar{n}$ holds, there exists in view of (1.109) a (unique) set $\bar{y}$ such that $\bar{y} = \emptyset$ holds, so that the implication (4.437) is evidently true (for the current constant $\bar{y} = \emptyset$). Moreover, since the current case assumption means that $\mathrm{dom}(\bar{g}) = \bar{n}$ is false, the implication (4.436) now has a false antecedent and is thus true (for the current constant $\bar{y}$). Consequently, the conjunction of (4.435), (4.436) and (4.437) is true for $\bar{y} = \emptyset$, so that (4.434) constitutes a true existential sentence for $\bar{x}$ and $\bar{y} = \emptyset$. This means that $\varphi(\bar{x}, \bar{y})$ is true for $\bar{y} = \emptyset$, which shows that the existential sentence $\exists y\,(\varphi(\bar{x}, y))$ holds also in the second case, completing the proof of that sentence by cases and thus the proof of the existential part.

To prove the uniqueness part, we verify

$$\forall y', y''\,([\varphi(\bar{x}, y') \,\wedge\, \varphi(\bar{x}, y'')] \Rightarrow y' = y''), \tag{4.438}$$

letting y' and y'' be arbitrary such that $\varphi(\bar{x}, y')$ and $\varphi(\bar{x}, y'')$ are both true. These two sentences mean in view of (4.434) that there are particular constants $\bar{n}', \bar{g}'$ as well as $\bar{n}'', \bar{g}''$ satisfying, respectively,

$$\begin{aligned} \bar{x} = (\bar{n}', \bar{g}') \;\wedge\; & [\mathrm{dom}(\bar{g}') = \bar{n}' \;\Rightarrow\; y' = \bar{g}' \cup \{(\bar{n}', F(\bar{g}'))\}] \\ \wedge\; & [\mathrm{dom}(\bar{g}') \neq \bar{n}' \;\Rightarrow\; y' = \emptyset] \end{aligned} \tag{4.439}$$

and

$$\bar{x} = (\bar{n}'', \bar{g}'') \;\wedge\; [\mathrm{dom}(\bar{g}'') = \bar{n}'' \;\Rightarrow\; y'' = \bar{g}'' \cup \{(\bar{n}'', F(\bar{g}''))\}] \\ \wedge\; [\mathrm{dom}(\bar{g}'') \neq \bar{n}'' \;\Rightarrow\; y'' = \emptyset]. \tag{4.440}$$

Recalling (4.435), the equations

$$(\bar{n}, \bar{g}) = \bar{x} = (\bar{n}', \bar{g}') = (\bar{n}'', \bar{g}'')$$

are then true, so that the equations

$$\bar{n} = \bar{n}' = \bar{n}'' \tag{4.441}$$

$$\bar{g} = \bar{g}' = \bar{g}'' \tag{4.442}$$

follow to be true with the Equality Criterion for ordered pairs. Let us now consider again the cases $\mathrm{dom}(\bar{g}) = \bar{n}$ and $\mathrm{dom}(\bar{g}) \neq \bar{n}$ to prove the sentence $y' = y''$. If $\mathrm{dom}(\bar{g}) = \bar{n}$ holds, then substitution based on (4.441) – (4.442) evidently yields the true equations

$$\mathrm{dom}(\bar{g}') = \bar{n}',$$
$$\mathrm{dom}(\bar{g}'') = \bar{n}'',$$

which then imply with the true implications in (4.439) – (4.440)

$$y' = \bar{g}' \cup \{(\bar{n}', F(\bar{g}'))\},$$
$$y'' = \bar{g}'' \cup \{(\bar{n}'', F(\bar{g}''))\}.$$

We may now carry out substitutions based on the equations (4.441) – (4.442) and based on the fact that $\bar{g} = \bar{g}'$ as well as $\bar{g} = \bar{g}''$ give $F(\bar{g}) = F(\bar{g}')$ as well as $F(\bar{g}) = F(\bar{g}'')$ (using the fact that F is a function in connection with Corollary 3.150), to obtain

$$y' = \bar{g} \cup \{(\bar{n}, F(\bar{g}))\}$$
$$y'' = \bar{g} \cup \{(\bar{n}, F(\bar{g}))\},$$

which equations yield the desired $y' = y''$ via substitution. If on the other hand $\mathrm{dom}(\bar{g}) \neq \bar{n}$ holds, then substitution based on (4.441) – (4.442) results in the true inequalities

$$\mathrm{dom}(\bar{g}') \neq \bar{n}',$$
$$\mathrm{dom}(\bar{g}'') \neq \bar{n}'',$$

which in turn imply with the true implications in (4.439) – (4.440)

$$y' = \emptyset,$$
$$y'' = \emptyset.$$

We therefore obtain $y' = y''$ again, so that the proof of this equation by cases is complete. Since y' and y'' were arbitrary, we may therefore conclude that (4.438) is true. Thus, the uniqueness part of $\exists! y\,(\varphi(\bar{x}, y))$ also holds, completing the proof of this uniquely existential sentence. Because $\bar{x}$ was also arbitrary, we may now further conclude that (4.433) is true, which universal sentence sentence then implies with Theorem 3.160 that there exists a unique function f with domain $\mathbb{N} \times B^{<\mathbb{N}}$ such that $\varphi(x, f(x))$ is true for all $x \in \mathbb{N} \times B^{<\mathbb{N}}$. Thus, every element $x \in \mathbb{N} \times B^{<\mathbb{N}}$ is associated with the unique value $f(x)$, where $x = (n, g)$ (for some n and g) is then evidently mapped according to (4.424) because of (4.434).

Concerning b), let us observe $\emptyset$ is a function from $\emptyset$ to B according to Proposition 3.151, where have $0 = \emptyset$ by definition of the number zero 0; thus, there is a natural number n such that $\emptyset$ is a function from n to B, so that $\emptyset \in B^{<\mathbb{N}}$ holds in view of Proposition 4.86. Together with the previously established defined function $f : \mathbb{N} \times B^{<\mathbb{N}} \to B^{<\mathbb{N}}$, this allows us to apply Method 4.3 to define the sequence $u : \mathbb{N} \to B^{<\mathbb{N}}$ by the recursion

$$\begin{aligned} &(1)\ \ u_0 &&= \emptyset, \\ &(2)\ \ u_{n^+} &&= f(n, u_n) \quad \text{for any } n \in \mathbb{N}. \end{aligned}$$

We now prove (4.427) by mathematical induction. Regarding the base case ($n = 0$), we recall the previously made observation that $u_0 = \emptyset$ is a function from 0 to B, thus an element of B^0. Regarding the induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption $u_n \in B^n$, and show that this implies $u_{n^+} \in B^{n^+}$. Using (4.426) and then the definition of the mapping f in (4.424) in connection with the fact that the induction assumption $u_n \in B^n$ gives $u_n : n \to B$ and therefore $\mathrm{dom}(u_n) = n$, we obtain the equations

$$u_{n^+} = f(n, u_n) = u_n \cup \{(n, F(u_n))\}. \tag{4.443}$$

Since $\in_{\mathbb{N}}$ is irreflexive (according to Corollary 4.5) so that $n \notin n$ holds (because of Lemma 4.4c)), we see that n is not an element of the domain n of u_n. Therefore, we may apply Proposition 3.177 to observe that

$$[u_{n^+} =] \quad u_n \cup \{(n, F(u_n))\} \tag{4.444}$$

is a function with domain $n \cup \{n\}$ $(= n^+)$ (recalling the definition of a successor), so that u_{n^+} is a function with domain n^+. Next, we verify that B is a codomain of u_{n^+}, by showing that $\mathrm{ran}(u_{n^+}) \subseteq B$ holds. To do this, we apply the definition of a subset and prove the equivalent

$$\forall y\,(y \in \mathrm{ran}(u_{n^+}) \Rightarrow y \in B). \tag{4.445}$$

We let y be arbitrary and assume $y \in \operatorname{ran}(u_{n^+})$, so that there exists by definition of a range a constant, say $\bar{n}$, such that $(\bar{n}, y) \in u_{n^+}$ holds. In view of (4.444), this implies with the definition of the union of two sets

$$(\bar{n}, y) \in u_n \lor (\bar{n}, y) \in \{(n, F(u_n))\},$$

and we may now use this true disjunction to prove the sentence $y \in B$ by cases. In the first case $(\bar{n}, y) \in u_n$, we obtain $y \in \operatorname{ran}(u_n)$ $[\subseteq B]$ with the definition of a range (recalling that B is codomain of u_n), and this finding implies the desired $y \in B$ with the definition of a subset. In the other case $(\bar{n}, y) \in \{(n, F(u_n))\}$, we obtain $(\bar{n}, y) = (n, F(u_n))$ with (2.169) and therefore in particular $y = F(u_n)$ with the Equality Criterion for ordered pairs. Since B is a codomain of F, we have $F(u_n) \in B$ according to the Function Criterion, so that substitution based on the preceding equation yields $y \in B$ also for the second case. This completes the proof by cases, and the truth of $y \in B$ proves in turn the implication in (4.445). Since y was arbitrary, we may therefore conclude that (4.445) holds, so that the range of u_{n^+} is indeed included in B. Thus, B is codomain also of u_{n^+}, so that u_{n^+} is a function from n^+ to B, and therefore u_{n^+} is an element of B^{n^+}. As n was arbitrary, we may now further conclude that the induction step holds, which completes the proof of (4.427) via by mathematical induction.

Concerning c), we apply the Monotony Criterion for isotone sequences of sets and prove

$$\forall n\, (n \in \mathbb{N} \Rightarrow u_n \subseteq u_{n^+}). \tag{4.446}$$

To do this, we let n be arbitrary in $\mathbb{N}$, so that (4.443) holds. Then, (2.201) shows that $u_n \subseteq u_n \cup \{(n, F(u_n))\}$ $[= u_{n^+}]$ is true. Thus, $u_n \subseteq u_{n^+}$ holds, which proves the implication in (4.446). As n is arbitrary, we may therefore infer from this the truth of the universal sentence (4.446). Due to Corollary 4.71a), it then follows that the sequence $(u_n)_{n \in \mathbb{N}}$ is indeed isotone, and this finding implies

$$\forall m, n\, ([m, n \in \mathbb{N} \land m <_{\mathbb{N}} n] \Rightarrow u_m \subseteq u_n) \tag{4.447}$$

by definition of an increasing sequence.

We now establish (4.428), letting u' be arbitrary and assuming $u' \in \operatorname{ran}(u)$ to be true. Consequently, there is (by definition of a range) a constant, say $\bar{m}$, such that $(\bar{m}, u') \in u$ holds. On the one hand, we may write the latter also in function/sequence notation as $u' = u_{\bar{m}}$. On the other hand, observing that $\operatorname{dom}(u) = \mathbb{N}$ holds, we obtain (by definition of a domain) $\bar{m} \in \mathbb{N}$, which in turn implies $[u' =]\; u_{\bar{m}} \in B^{\bar{m}}$ with (4.427). We thus showed that the conjunction $\bar{m} \in \mathbb{N} \land u' = u_{\bar{m}} \land u' \in B^{\bar{m}}$ is true, so that the desired existential sentence in (4.428) holds. Since u' was arbitrary, we may therefore conclude that (4.428) is true.

Next, we verify that the previously established facts imply the compatibility of the range of the sequence $u = (u_n)_{n\in\mathbb{N}}$ in $B^{<\mathbb{N}}$. For this purpose, we take arbitrary $u', u'' \in \mathrm{ran}(u)$, so that there are in view of (4.428) natural numbers, say $\bar{m}$ and $\bar{n}$, with $u' = u_{\bar{m}}$ $[\in B^{\bar{m}}]$ and $u'' = u_{\bar{n}}$ $[\in B^{\bar{n}}]$. Thus, $u_{\bar{m}}$ and $u_{\bar{n}}$ are functions (with codomain B), and we now show that $u_{\bar{m}}$ and $u_{\bar{n}}$ are compatible. To do this, we apply Proposition 3.172 and show accordingly that one of the functions is a subset of the other one. Using now the standard total ordering $\leq_{\mathbb{N}}$ of $\mathbb{N}$, we have the true disjunction

$$\bar{m} \leq_{\mathbb{N}} \bar{n} \vee \bar{n} \leq_{\mathbb{N}} \bar{m}, \tag{4.448}$$

which we now use to prove by cases that $u_{\bar{m}}$ and $u_{\bar{n}}$ are compatible. In the first case that $\bar{m} \leq_{\mathbb{N}} \bar{n}$, we obtain $\bar{m} <_{\mathbb{N}} \bar{n} \vee \bar{m} = \bar{n}$ with the Characterization of induced irreflexive partial orderings, and we now prove the sentence $u_{\bar{m}} \subseteq u_{\bar{n}}$ by cases based on that true disjunction. If $\bar{m} <_{\mathbb{N}} \bar{n}$ holds, then that inclusion follows immediately to be true with (4.447). If $\bar{m} = \bar{n}$ holds, then we obtain $u_{\bar{m}} = u_{\bar{n}}$ because u is a function (which thus satisfies Corollary 3.150); then, the disjunction $u_{\bar{m}} \subset u_{\bar{n}} \vee u_{\bar{m}} = u_{\bar{n}}$ is also true (regardless of the truth value of its first part), and this disjunction yields the desired $u_{\bar{m}} \subseteq u_{\bar{n}}$ with (2.26), completing this proof by cases. The preceding inclusion then implies with Proposition 3.172 that the functions $u_{\bar{m}}$ and $u_{\bar{n}}$ are compatible (in case of $\bar{m} \leq_{\mathbb{N}} \bar{n}$). In case the second part $\bar{n} \leq_{\mathbb{N}} \bar{m}$ of the disjunction (4.448) is true, so that we now obtain $\bar{n} <_{\mathbb{N}} \bar{m} \vee \bar{n} = \bar{m}$, we may apply a proof by cases (similarly to the one for the first case) to establish $u_{\bar{n}} \subseteq u_{\bar{m}}$. If $\bar{n} <_{\mathbb{N}} \bar{m}$ holds, then (4.447) yields already the desired inclusion. If $\bar{n} = \bar{m}$ holds, then $u_{\bar{n}} = u_{\bar{m}}$ also holds (exploiting again the fact that u is a function), and the disjunction $u_{\bar{n}} \subset u_{\bar{m}} \vee u_{\bar{n}} = u_{\bar{m}}$ is therefore true as well, which implies the desired inclusion $u_{\bar{n}} \subseteq u_{\bar{m}}$ (using again (2.26)). Thus, the preceding inclusion holds in any case, so that we may now apply once again Proposition 3.172 to infer from this finding that $u_{\bar{n}}$ and $u_{\bar{m}}$ are compatible. Because of Corollary 3.171, it then follows that $u_{\bar{m}}$ and $u_{\bar{n}}$ are compatible, as in the first case. This completes the proof by cases based on the disjunction (4.448), and we apply now substitutions to infer from the compatibility of $u_{\bar{m}}$ and $u_{\bar{n}}$ the compatibility of u' and u''. Since u' and u'' were arbitrary, we may therefore conclude that the range of $u = (u_n)_{n\in\mathbb{N}}$ is a compatible set of functions.

Concerning d), we may now apply Theorem 3.175 to the range of $u = (u_n)_{n\in\mathbb{N}}$ to obtain the function

$$v = \bigcup \mathrm{ran}(u).$$

We now verify that the domain of v equals $\mathbb{N}$. According to Theorem 3.175, we have $\mathrm{dom}(v) = \bigcup \mathcal{D}$, where $\mathcal{D}$ consists of the domains of all the functions in $(u_n)_{n\in\mathbb{N}}$, i.e. where

$$\mathcal{D} = \{D : \exists u' \,(u' \in \mathrm{ran}(u) \,\wedge\, \mathrm{dom}(u') = D)\}. \tag{4.449}$$

Due to Equality Criterion for sets, we may prove [$\mathrm{dom}(v) =$] $\bigcup\mathcal{D} = \mathbb{N}$ by verifying equivalently

$$\forall n \,(n \in \bigcup\mathcal{D} \Leftrightarrow n \in \mathbb{N}). \tag{4.450}$$

To do this, we let n be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $n \in \bigcup\mathcal{D}$. By definition of the union of a set system, there then exists a set, say $\bar{D}$, such that $\bar{D} \in \mathcal{D}$ and $n \in \bar{D}$ hold. In light of the definition of $\mathcal{D}$, we now see that $\bar{D} \in \mathcal{D}$ implies that there exists an element of the range of u, say $\bar{u}'$, with $\mathrm{dom}(\bar{u}') = \bar{D}$. With this equation, the previously established $n \in \bar{D}$ yields $n \in \mathrm{dom}(\bar{u}')$. Furthermore, $\bar{u}' \in \mathrm{ran}(u)$ implies with (4.428) the existence of a particular $\bar{m} \in \mathbb{N}$ [$= \mathrm{dom}(u)$] with $\bar{u}' = u_{\bar{m}}$ and $u_{\bar{m}} \in B^{\bar{m}}$. Thus, $\mathrm{dom}(\bar{u}') = \bar{m}$, and therefore the previously established $n \in \mathrm{dom}(\bar{u}')$ yields $n \in \bar{m}$. Since $\bar{m} \in \mathbb{N}$ also implies $\bar{m} \subseteq \mathbb{N}$ with (2.320), we have that $n \in \bar{m}$ implies the desired $n \in \mathbb{N}$ by definition of a subset. This finding proves the first part of the equivalence in (4.450).

To prove the second part ('$\Leftarrow$'), we now assume $n \in \mathbb{N}$, which implies on the one hand $n \in n^+$ with (2.305) and on the other hand $n^+ \in \mathbb{N}$ with (2.297). The latter yields $u_{n^+} \in B^{n^+}$ with (4.427), so that u_{n^+} is a function with domain n^+ (and codomain B). Since u_{n^+} is a term of the sequence u with index n^+, so that $(n^+, u_{n^+}) \in u$ holds, we obtain $u_{n^+} \in \mathrm{ran}(u)$ by definition of a range. Thus, the conjunction of $u_{n^+} \in \mathrm{ran}(u)$ and $\mathrm{dom}(u_{n^+}) = n^+$ is true, which shows that the existential sentence in (4.449) is satisfied by $\bar{D} = n^+$. This equation gives on the one hand $\bar{D} \in \mathcal{D}$ by definition of $\mathcal{D}$ in (4.449), and on the other hand it allows us to apply substitution to the previously established $n \in n^+$ to obtain $n \in \bar{D}$. Now, since $\bar{D} \in \mathcal{D}$ and $n \in \bar{D}$ are both true, we see that there exists a set D which satisfies $D \in \mathcal{D} \wedge n \in D$, and this existential sentences further implies $n \in \bigcup\mathcal{D}$ by definition of the union of a set system. This completes the proof of the second part of the equivalence in (4.450), and since n was arbitrary, we may therefore conclude that the (4.450) is true. This universal sentence in turn implies the equation [$\mathrm{dom}(v) =$] $\bigcup\mathcal{D} = \mathbb{N}$ with the Equality Criterion for sets. We therefore obtain $\mathrm{dom}(v) = \mathbb{N}$, which shows that v is a sequence with domain $\mathbb{N}$.

Next, we verify that v is a sequence in B, i.e. that $\mathrm{ran}(v) \subseteq B$ holds. For this purpose, we prove the equivalent (applying the definition of a subset)

$$\forall y \,(y \in \mathrm{ran}(v) \Rightarrow y \in B). \tag{4.451}$$

To do this, we let y be arbitrary and assume $y \in \operatorname{ran}(v)$ to be true. By definition of a range, there then exists a constant, say $\bar{n}$, such that $(\bar{n}, y) \in v$ holds. With the equation (4.429), it then follows that $(\bar{n}, y) \in \bigcup \operatorname{ran}(u)$, which implies (by definition of the union of a set system) that there exists a set, say $\bar{u}'$, with $\bar{u}' \in \operatorname{ran}(u)$ and $(\bar{n}, y) \in \bar{u}'$ are true. Here, the latter shows that y is an element of the range of $\bar{u}'$. Due to (4.428), we have that $\bar{u}' \in \operatorname{ran}(u)$ implies the existence of a particular constant $\bar{m}$ such that $\bar{m} \in \mathbb{N}$, $\bar{u}' = u_{\bar{m}}$ and $\bar{u}' \in B^{\bar{m}}$ hold, so that $\bar{u}'$ is a function from $\bar{m}$ to B. Thus, $\operatorname{ran}(\bar{u}') \subseteq B$ holds by definition of a codomain, and therefore the previously found $y \in \operatorname{ran}(\bar{u}')$ gives $y \in B$ (with the definition of a subset). As y is arbitrary, we may now conclude that (4.451) is true, which universal sentence yields (again by definition of a subset) $\operatorname{ran}(v) \subseteq B$, so that v is a function/sequence with codomain B.

We now prove (4.430), letting n be arbitrary in $\mathbb{N}$. To demonstrate the truth of the equation $v \upharpoonright n = u_n$, we use again the Equality Criterion for sets and verify equivalently

$$\forall z\,(z \in v \upharpoonright n \Leftrightarrow z \in u_n). \tag{4.452}$$

For this purpose, we let z be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $z \in v \upharpoonright n$. This implies by definition of a binary relation that there exist constants, say $\bar{k}$ and $\bar{y}$ such that $z = (\bar{k}, \bar{y})$. Thus, $(\bar{k}, \bar{y}) \in v \upharpoonright n$ holds, where n is the domain of the restriction $v \upharpoonright n$ according to Proposition 3.164, so that we obtain $\bar{k} \in n$ (with the definition of a domain). Because the assumed $n \in \mathbb{N}$ implies $u_n \in B^n$ with (4.427), we see that n is also the domain of u_n, so that $\bar{k} \in n$ yields $\bar{k} \in \operatorname{dom}(u_n)$. Then, by definition of a domain, there exists a constant, say $\bar{y}'$, such that

$$(\bar{k}, \bar{y}') \in u_n. \tag{4.453}$$

Moreover, the previously established $(\bar{k}, \bar{y}) \in v \upharpoonright n$ implies $(\bar{k}, \bar{y}) \in v$ with the definition of a restriction, so that we see in light of (4.429) and the definition of the union of a set system that there exists an element of the range of $u = (u_n)_{n \in \mathbb{N}}$, say $\bar{u}'$, such that $(\bar{k}, \bar{y}) \in \bar{u}'$ holds. Here, $\bar{u}' \in \operatorname{ran}(u)$ implies with (4.428) that $\bar{u}' = u_{\bar{m}}$ and $\bar{u}' \in B^{\bar{m}}$ hold for a particular $\bar{m} \in \mathbb{N}$, so that we obtain via substitution

$$(\bar{k}, \bar{y}) \in u_{\bar{m}}. \tag{4.454}$$

We now show that the conjunction of (4.453) and (4.454) implies $\bar{y}' = \bar{y}$. We could establish this equation by performing two nested proofs by cases in analogy to the compatibility proof in c). For a change, we use here

Method 1.13 as a variant of the proof by cases, utilizing the connexity of the standard linear ordering $<_{\mathbb{N}}$, so that the disjunction

$$\bar{m} <_{\mathbb{N}} n \lor n <_{\mathbb{N}} \bar{m} \lor \bar{m} = n$$

is true. In the first case $\bar{m} <_{\mathbb{N}} n$, the inclusion $u_{\bar{m}} \subseteq u_n$ follows with (4.447), so that (4.454) implies $(\bar{k}, \bar{y}) \in u_n$ with the definition of a subset. Then, the conjunction of this and (4.453) implies $\bar{y} = \bar{y}'$ because u_n is a function, as noted earlier. Similarly, we obtain in the second case $n <_{\mathbb{N}} \bar{m}$ the inclusion $u_n \subseteq u_{\bar{m}}$, so that (4.453) implies $(\bar{k}, \bar{y}') \in u_{\bar{m}}$. The conjunction of this and (4.454) then yields $\bar{y}' = \bar{y}$ because the previously established $\bar{u}' \in B^{\bar{m}}$ shows that $u_{\bar{m}}$ $[= \bar{u}']$ is a function. Finally, the third case $\bar{m} = n$ yields $u_{\bar{m}} = u_n$ with the fact that u is a function/sequence (which thus satisfies Corollary 3.150). Then, applying substitution based on that equation to (4.454), we obtain $(\bar{k}, \bar{y}) \in u_n$, so that $\bar{y} = \bar{y}'$ follows to be true as in the first case of $\bar{m} <_{\mathbb{N}} n$. Thus, the proof by cases is complete, so that substitution of the preceding equation into (4.453) gives $[(\bar{k}, \bar{y}) =]\ z \in u_n$, which finding proves the first part of the equivalence in (4.452).

To prove the second part ('$\Leftarrow$'), we now assume $z \in u_n$, so that (by definition of a binary relation) there exist constants, say $\bar{k}$ and $\bar{y}$, such that $(\bar{k}, \bar{y}) \in u_n$. This implies together with $u_n \in \mathrm{ran}(u)$ (which evidently holds since u_n is a value of the function u) the truth of $(\bar{k}, \bar{y}) \in \bigcup \mathrm{ran}(u)$ (using the definition of the union of a set system), so that $(\bar{k}, \bar{y}) \in v$ holds in view of (4.429). By definition of a domain, it also follows from $(\bar{k}, \bar{y}) \in u_n$ that $\bar{k} \in \mathrm{dom}(u_n)$, which yields $\bar{k} \in n$ because n is the domain of u_n according to (4.427). Then, since $(\bar{k}, \bar{y}) \in v$ and $\bar{k} \in n$ are both true, it follows with the definition of a restriction that $(\bar{k}, \bar{y}) \in v \upharpoonright n$, which proves the second part of the equivalence in (4.452). As z is arbitrary, we may therefore conclude that (4.452) is true, which means that $v \upharpoonright n$ and u_n are identical sets. Since n was also arbitrary, we may then further conclude that (4.430) holds.

Concerning e), we first show that the sequence v defined by (4.429) satisfies (4.431). To do this, we let $n \in \mathbb{N}$ be arbitrary and observe first the truth of the equations

$$v \upharpoonright n^+ = u_{n^+} = f(n, u_n) = u_n \cup \{(n, F(u_n))\} \tag{4.455}$$

using firstly (4.430) with the fact that $n \in \mathbb{N}$ implies $n^+ \in \mathbb{N}$ with (2.297), secondly (4.426), and thirdly the definition of the function f in (4.424) in connection with the fact that $\mathrm{dom}(u_n) = n$ holds because $n \in \mathbb{N}$ implies $u_n \in B^n$ according to (4.427). Since $(n, F(u_n)) \in \{(n, F(u_n))\}$ holds in view of (2.153), it then follows with the definition of the union of two sets that $(n, F(u_n))$ is an element of $u_n \cup \{(n, F(u_n))\}$, which yields $(n, F(u_n)) \in$

$v \restriction n^+$ via substitution based on the equations in (4.455). This implies with the definition of a restriction that $(n, F(u_n)) \in v$ holds, which we may also write

$$v_n = F(u_n) \tag{4.456}$$

due to the fact established in d) that v is a sequence/function. Since $n \in \mathbb{N}$ also implies $u_n = v \restriction n$ with (4.430), we obtain $F(u_n) = F(v \restriction n)$ with the initial assumption that F is a function (which thus satisfies Corollary 3.150). Combining now the preceding equation with the equation (4.456), we therefore arrive at the desired equation $v_n = F(v \restriction n)$. As n is arbitrary, we may therefore conclude that the universal sentence (4.431) is true for the sequence $(v_n)_{n\in\mathbb{N}} = v$ defined in (4.429).

To prove that v is the only sequence satisfying (4.429), we verify (according to Method 1.18) the universal sentence (4.432). We let v' be arbitrary such that v' is a sequence in B with domain $\mathbb{N}$ satisfying (4.431). To prove that this implies $v = v'$, we apply the Equality Criterion for functions and demonstrate accordingly the truth of

$$\forall n\,(n \in \mathbb{N} \Rightarrow v_n = v'_n). \tag{4.457}$$

We now prove this universal sentence by strong induction, based on the induction step

$$\forall n\,(n \in \mathbb{N} \Rightarrow [\forall m\,([m \in \mathbb{N} \wedge m <_{\mathbb{N}} n] \Rightarrow v_m = v'_m) \Rightarrow v_n = v'_n]). \tag{4.458}$$

To prove this sentence, we let n be arbitrary in $\mathbb{N}$, make the induction assumption

$$\forall m\,([m \in \mathbb{N} \wedge m <_{\mathbb{N}} n] \Rightarrow v_m = v'_m), \tag{4.459}$$

and show that this implies $v_n = v'_n$. We begin with the proof that the induction assumption implies $v \restriction n = v' \restriction n$, which is equivalent to

$$\forall z\,(z \in v \restriction n \Leftrightarrow z \in v' \restriction n) \tag{4.460}$$

due to the Equality Criterion for sets. Letting z be arbitrary, we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $z \in v \restriction n$ is true. Since $v \restriction n$ is a binary relation, there exist constants, say $\bar{k}$ and $\bar{y}$, such that $z = (\bar{k}, \bar{y})$. Thus, $(\bar{k}, \bar{y}) \in v \restriction n$, which implies $(\bar{k}, \bar{y}) \in v$ and $\bar{k} \in n$ with the definition of a restriction in connection with the previously mentioned fact that n is the domain of $v \restriction n$. Then, $\bar{k} \in n$ implies with (4.190) that $\bar{k} <_{\mathbb{N}} n$, which further implies $v_{\bar{k}} = v'_{\bar{k}}$ with the induction assumption. As the previously obtained $(\bar{k}, \bar{y}) \in v$ may be written in function/sequence notation as $v_{\bar{k}} = \bar{y}$, we obtain after substitution $v'_{\bar{k}} = \bar{y}$, which then means $(\bar{k}, \bar{y}) \in v'$, and thus $z \in v'$. Now, the conjunction of this and the previously established $\bar{k} \in n$ yields (by definition of a restriction) the desired $z \in v' \restriction n$, which proves the first part of the equivalence in (4.460).

The second part ('$\Leftarrow$') is proved in analogy to the first part. Assuming now $z \in v' \restriction n$ to be true, we again have $z = (\bar{k}, \bar{y})$ for some particular $\bar{k}$ and $\bar{y}$, so that $(\bar{k}, \bar{y}) \in v' \restriction n$ holds. This implies $(\bar{k}, \bar{y}) \in v'$ and $\bar{k} \in n$, where the latter further implies $\bar{k} <_{\mathbb{N}} n$ and therefore $v_{\bar{k}} = v'_{\bar{k}}$ with the induction assumption. Now, $(\bar{k}, \bar{y}) \in v'$ means $v'_{\bar{k}} = \bar{y}$, so that $v_{\bar{k}} = \bar{y}$ holds, which we may write as $(\bar{k}, \bar{y}) \in v$. This equation yields $z \in v$, which then implies, together with $\bar{k} \in n$, the desired $z \in v \restriction n$, completing the proof of the equivalence. As z is arbitrary, we may therefore conclude that (4.460) is true, so that

$$v \restriction n = v' \restriction n \tag{4.461}$$

holds indeed. Let us then observe the truth of the equations

$$v_n = F(v \restriction n) = F(v' \restriction n) = v'_n,$$

using (4.431), then Corollary 3.526 in connection with (4.461) and the assumption that F is a function, and finally again (4.431). These equations give the desired $v_n = v'_n$, and since n was arbitrary, we may therefore conclude that (4.458) holds. This completes the proof of (4.457) via strong induction, so that $v = v'$ follows to be true. This equation in turn proves the implication in (4.432), and as v' was arbitrary, we may finally conclude that the universal sentence (4.432) holds, completing the proof of e).

Since B and F were initially arbitrary sets in the proofs of a) – e), the stated theorem follows then to be true. □

In view Proposition 1.22 we may summarize the Strong Recursion Theorem as follows.

Corollary 4.97. *For any set B and any function $F : B^{<\mathbb{N}} \to B$ there exists a unique sequence $v = (v_n)_{n \in \mathbb{N}}$ in B satisfying*

$$\forall n\,(n \in \mathbb{N} \Rightarrow v_n = F(v \restriction n)).$$

4.7. Denumerations

Definition 4.9 (Denumeration, length of a denumeration). For any set A and any $n \in \mathbb{N}$ we say that a set c is a *denumeration* of A of *length* n iff c is a bijection from the initial segment of $\mathbb{N}_+$ up to n to A, i.e. iff

$$c : \{1, \ldots, n\} \rightleftarrows A. \tag{4.462}$$

Note 4.18. In the case of $A = \emptyset$, we have that $\emptyset : \{1, \ldots, 0\} \rightleftarrows A$ is a bijection due to (4.239) and Corollary 3.201; thus, the denumeration of the empty set has the anticipated length $n = 0$.

4.7.1. Finite sets

Apparently, if the domain of a denumeration of some set A 'ends' at some natural number n, then A cannot have an 'infinite' number of elements.

Definition 4.10 (Finite & infinite set). We say that a set A is *finite* iff there is a natural number n such that there exists a denumeration of A of length n, i.e. iff

$$\exists n, c\, (n \in \mathbb{N} \wedge c : \{1, \ldots, n\} \rightleftarrows A). \tag{4.463}$$

Furthermore, we say that a set A is *infinite* iff A is not a finite set, i.e. iff the negation of (4.463) is true.

Corollary 4.98. *Every natural number is a finite set, that is,*

$$\forall n\, (n \in \mathbb{N} \Rightarrow n \text{ is finite}). \tag{4.464}$$

Proof. Letting m be an arbitrary natural number, we observe in light of Proposition 4.61 that $s^+ \upharpoonright m$ is a bijection from m to $\{1, \ldots, m\}$, i.e.

$$s^+ \upharpoonright m : m \rightleftarrows \{1, \ldots, m\}. \tag{4.465}$$

It then follows with Theorem 3.212 that the inverse function $(s^+ \upharpoonright m)^{-1}$ is a bijection from $\{1, \ldots, m\}$ to m, i.e.

$$(s^+ \upharpoonright m)^{-1} : \{1, \ldots, m\} \rightleftarrows m. \tag{4.466}$$

Thus, there exists a natural number n and a bijection c from $\{1, \ldots, n\}$ to m, so that m is a finite set by definition. □

Proposition 4.99. *The union of a finite set and a singleton is finite, i.e.*

$$\forall A, y\, (A \text{ is finite } \Rightarrow A \cup \{y\} \text{ is finite}). \tag{4.467}$$

Proof. We let A and y be arbitrary and prove the implication by cases, considering the two exhaustive cases $y \in A$ and $y \notin A$.

In the first case, we assume that A is finite and that $y \in A$ holds. The latter implies $\{y\} \subseteq A$ with (2.184), which then further implies $\{y\} \cup A = A$ with (2.247), and therefore $A \cup \{y\} = A$ using (2.214). Since A is finite, we thus have that $A \cup \{y\}$ is also finite.

In the second case, we assume that A is finite where $y \notin A$. By definition of a finite set, the former assumption implies that there exist a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to A, say $\bar{c}$. Here, $\bar{n} \in \mathbb{N}$ implies $\bar{n} = 0 \lor \bar{n} \in \mathbb{N}_+$ with (2.310), which disjunction we now use to prove by cases that the union $A \cup \{y\}$ is finite. If $\bar{n} = 0$ is true, we have the bijection $\bar{c} : \{1, \ldots, 0\} \rightleftarrows A$; thus, the domain of $\bar{c}$ is empty according to the notation for initial segments of $\mathbb{N}_+$, so that $1 \notin \emptyset$ is true by definition of the empty set. Together with the assumed $y \notin A$, we obtain with (3.667) the bijection $\bar{c} \cup \{(1, y)\}$ from $\emptyset \cup \{1\}$ to $A \cup \{y\}$, i.e.

$$\bar{c} \cup \{(1, y)\} : \{1, \ldots, \bar{n}^+\} \rightleftarrows A \cup \{y\}, \tag{4.468}$$

using (2.216) and (2.291) with the definition of an initial segment. Since $\bar{n}^+ = 1$ is a natural number, this bijection shows that $A \cup \{y\}$ is a finite set for $\bar{n} = 0$.

If $\bar{n} \in \mathbb{N}_+$ is true, then we have that $\bar{n}^+ \notin \{1, \ldots, \bar{n}\}$ holds according to Corollary 4.55b). Together with the assumption $y \notin A$, this implies with (3.667) that $\bar{c} \cup \{(\bar{n}^+, y)\}$ is a bijection from $\{1, \ldots, \bar{n}\} \cup \{\bar{n}^+\}$ to $A \cup \{y\}$, so that we obtain by means of (4.241)

$$\bar{c} \cup \{(\bar{n}^+, y)\} : \{1, \ldots, \bar{n}^+\} \rightleftarrows A \cup \{y\}. \tag{4.469}$$

As $\bar{n} \in \mathbb{N}$ implies $\bar{n}^+ \in \mathbb{N}$ with (2.297), (4.469) shows that there are a natural number n and a bijection from $\{1, \ldots, n\}$ to $A \cup \{y\}$, so that $A \cup \{y\}$ is finite by definition. This completes the proof of the implication by cases, and since A and y were arbitrary, we may therefore conclude that the proposition holds, as claimed. □

Corollary 4.100. *Any singleton is finite, that is,*

$$\forall y \, (\{y\} \text{ is finite}). \tag{4.470}$$

Proof. Letting y be arbitrary, we obtain $\{y\} = \emptyset \cup \{y\}$ with (2.216), where $\emptyset$ is a finite set by definition. We then see in light of (4.467) that $\emptyset \cup \{y\}$ and thus the singleton $\{y\}$ is finite. Since y was arbitrary, we may therefore conclude that (4.470) is true. □

Exercise 4.34. Show for any $m \in \mathbb{N}$ that the initial segment $A = \{1, \ldots, m\}$ of $\mathbb{N}_+$ up to m is finite.

(Hint: Apply Corollary 3.203.)

Lemma 4.101. *For any natural number m and any positive natural number n, it is true that there is no injection from the initial segment $\{1, \ldots, m^+\}$ to the initial segment $\{1, \ldots, n\}$ if n is less than m^+, that is,*

$$\forall m, n\,([m \in \mathbb{N} \wedge n \in \mathbb{N}_+] \Rightarrow$$
$$[n < m^+ \Rightarrow \neg \exists f\,(f \in \{1, \ldots, n\}^{\{1,\ldots,m^+\}} \wedge f \text{ is an injection})]). \quad (4.471)$$

Proof. Let us rewrite the proposed sentence equivalently as

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \forall m\,(m \in \mathbb{N} \Rightarrow \quad (4.472)$$
$$[n < m^+ \Rightarrow \forall f\,(f \in \{1, \ldots, n\}^{\{1,\ldots,m^+\}} \Rightarrow f \text{ is not an injection})])).$$

using (1.90) and (1.81). We now prove this sentence by mathematical induction. Regarding the base case ($n = 1$), we prove accordingly

$$\forall m\,(m \in \mathbb{N} \Rightarrow \quad (4.473)$$
$$[1 < m^+ \Rightarrow \forall f\,(f \in \{1, \ldots, 1\}^{\{1,\ldots,m^+\}} \Rightarrow f \text{ is not an injection})]).$$

For this purpose, we let m be arbitrary in $\mathbb{N}$, assume $1 < m^+$, let then f be arbitrary, and prove the inner implication by contradiction, assuming that f is a function from $\{1, \ldots, m^+\}$ to $\{1, \ldots, 1\}$, i.e. from $\{1, \ldots, m^+\}$ to $\{1\}$, and that f is an injection, so that

$$\forall x, x'\,([x, x' \in \{1, \ldots, m^+\} \wedge x \neq x'] \Rightarrow f(x) \neq f(x')) \quad (4.474)$$

holds according to the Injection Criterion. Let us now observe that $m \in \mathbb{N}$ implies $m^+ \in \mathbb{N}_+$ with (4.40), and that $1, m^+ \in \{1, \ldots, m^+\}$ holds then according to Corollary 4.54. Thus, the domain of f is nonempty, so that $\mathrm{ran}(f) \neq \emptyset$ follows to be true with (3.119) and the Law of Contraposition. Since the codomain $\{1\}$ of f is a singleton, $\exists! y(y \in \{1\})$ holds according to (2.180). Now, as 1 and m^+ are elements of the domain $\{1, \ldots, m^+\}$ of the function f, it follows with the Function Criterion that there exist the unique values $y = f(1)$ and $y' = f(m^+)$ in $\{1\}$. Then, $y \in \{1\}$ and $y' \in \{1\}$ imply $y = y'$ with the preceding uniquely existential sentence, so that substitution yields $f(1) = f(m^+)$. Furthermore, the assumption $1 < m^+$ implies $1 \neq m^+$ with the comparability of the linear ordering $<$ of $\mathbb{N}$. It then follows with (4.474) that $f(1) \neq f(m^+)$ is true, which contradicts the previously established equation $f(1) = f(m^+)$. This completes the proof by contradiction, and since f is arbitrary, we may therefore conclude that the universal sentence in (4.473) with respect to f is true. Because m was also arbitrary, we may then further conclude that (4.473) holds, which proves the base case.

Regarding the induction step, we let n be arbitrary in $\mathbb{N}_+$, make the induction assumption

$$\forall m\,(m \in \mathbb{N} \Rightarrow \tag{4.475}$$
$$[n < m^+ \Rightarrow \forall f\,(f \in \{1,\ldots,n\}^{\{1,\ldots,m^+\}} \Rightarrow f \text{ is not an injection})]),$$

and show that this implies

$$\forall m\,(m \in \mathbb{N} \Rightarrow \tag{4.476}$$
$$[n^+ < m^+ \Rightarrow \forall f\,(f \in \{1,\ldots,n^+\}^{\{1,\ldots,m^+\}} \Rightarrow f \text{ is not an injection})]).$$

To prove the latter, we let m be arbitrary in $\mathbb{N}$, assume $n^+ < m^+$, and let f be an arbitrary function from $\{1,\ldots,m^+\}$ to $\{1,\ldots,n^+\}$. Since m^+ and n^+ are elements of $\mathbb{N}_+$, we may apply (4.272) alongside (4.187) to infer from the assumed $n^+ < m^+$ the truth of $[0 \leq]\ n < m$, so that the Transitivity Formula for $\leq$ and $<$ as well as the comparability of $<$ yield first $0 < m$ and then $0 \neq m$, which inequality clearly shows that $m \in \mathbb{N}_+$ is also true. Let us now observe that the disjunction

$$\operatorname{ran}(f) \subseteq \{1,\ldots,n\} \vee \neg\operatorname{ran}(f) \subseteq \{1,\ldots,n\} \tag{4.477}$$

is true according to the Law of the Excluded Middle, which disjunction we now use to prove by cases that f is not an injection.

In case $\operatorname{ran}(f) \subseteq \{1,\ldots,n\}$ is true, then f is a function from $\{1,\ldots,m^+\}$ to $\{1,\ldots,n\}$ by definition of a codomain. The conjunction of the fact $n < n^+$ (see 4.153) and the assumption $n^+ < m^+$ implies $n < m^+$ with the transitivity of the linear ordering $<$, which inequality then further implies together with the preceding finding $f \in \{1,\ldots,n\}^{\{1,\ldots,m^+\}}$ and the induction assumption that $f : \{1,\ldots,m^+\} \to \{1,\ldots,n\}$ is not an injection. It then follows with Note 3.23 that $f : \{1,\ldots,m^+\} \to \{1,\ldots,n^+\}$ is not an injection either (because the definite property of injectivity is independent of the choice for the codomain).

In case the second part $\neg\operatorname{ran}(f) \subseteq \{1,\ldots,n\}$ of the disjunction (4.477) is true, this means by definition of a subset that

$$\neg\forall y\,(y \in \operatorname{ran}(f) \Rightarrow y \in \{1,\ldots,n\})$$

holds. In view of the Negation Law for universal implications, there then exists an element of $\operatorname{ran}(f)$, say $\bar{y}$, such that $\bar{y} \notin \{1,\ldots,n\}$. Furthermore,

$\bar{y} \in \operatorname{ran}(f)$ implies $\bar{y} \in \{1, \ldots, n^+\}$, because we assumed that f is a function with codomain $\{1, \ldots, n^+\}$, so that $\operatorname{ran}(f) \subseteq \{1, \ldots, n^+\}$ holds. Thus, the conjunction

$$\bar{y} \in \{1, \ldots, n^+\} \land \bar{y} \notin \{1, \ldots, n\}$$

holds, which means $\bar{y} \in \{1, \ldots, n^+\} \setminus \{1, \ldots, n\}$ by definition of a set difference, and therefore $\bar{y} \in \{n^+\}$ is true according to (4.257). Then, this finding implies $\bar{y} = n^+$ with (2.169). As n^+ is thus an element of $\operatorname{ran}(f)$, there exists (by definition of a range) a constant, say $\bar{x}^+$, such that $(\bar{x}^+, n^+) \in f$ holds, which we may write as $f(\bar{x}^+) = n^+$; then, we obtain with the definition of a domain $\bar{x}^+ \in \{1, \ldots, m^+\}$. To make further progress, we notice in light of the Law of the Excluded Middle that the disjunction of

$$\exists k \left([k \in \{1, \ldots, m^+\} \land \bar{x}^+ \neq k] \land f(\bar{x}^+) = f(k) \right) \tag{4.478}$$

and the negation of (4.478) is true, which disjunction we apply to prove by cases that f is not an injection.

If (4.478) is true, then there is a particular constant $\bar{k} \in \{1, \ldots, m^+\}$ with $\bar{x}^+ \neq \bar{k}$ and $f(\bar{x}^+) = f(\bar{k})$. Recalling the previously established $\bar{x}^+ \in \{1, \ldots, m^+\}$, we obtain the existential sentence

$$\exists x, x' \left(x, x' \in \{1, \ldots, m^+\} \land x \neq x' \land f(x) = f(x') \right),$$

which in turn implies with Exercise 3.77 that f is not an injection (as desired).

If the negation of (4.478) is true, then the Negation Law for existential conjunction yields the universal sentence

$$\forall k \left([k \in \{1, \ldots, m^+\} \land \bar{x}^+ \neq k] \Rightarrow n^+ \neq f(k) \right). \tag{4.479}$$

it is apparently true that the range of $f \setminus \{(\bar{x}^+, n^+)\}$ now excludes n^+, because no element of $\{1, \ldots, m^+\}$ distinct from $\bar{x}^+$ is associated with n^+. We now utilize this idea to define via replacement a new function g with domain $\{1, \ldots, m\}$ which satisfies

$$x \mapsto g(x) = \begin{cases} f(x) & \text{if } x \in \{1, \ldots, \bar{x}\}, \\ f(x^+) & \text{if } x \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\}. \end{cases} \tag{4.480}$$

We prove for this purpose

$$\begin{aligned} &\forall x \left(x \in \{1, \ldots, m\} \Rightarrow \exists! y \left([x \in \{1, \ldots, \bar{x}\} \Rightarrow y = f(x)] \right.\right. \\ &\quad \left.\left. \land [x \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\} \Rightarrow y = f(x^+)] \right) \right), \end{aligned} \tag{4.481}$$

letting x be arbitrary and assuming $x \in \{1, \ldots, m\}$ to be true, where the initial segment $\{1, \ldots, m\}$ of $\mathbb{N}_+$ is indeed nonempty due to the previously established fact that $m \in \mathbb{N}_+$ holds; thus $x \in \mathbb{N}_+$. Let us now observe that the previously found $\bar{x}^+ \in \{1,\ldots,m^+\}$ implies $\bar{x}^+ \leq m^+$ with (4.275), which inequality further implies $\bar{x} \leq m$ with (4.273), and this gives $\{1,\ldots,\bar{x}\} \subseteq \{1,\ldots,m\}$ with (4.258) and (4.261). It then follows with (2.263) that

$$\{1,\ldots,m\} = (\{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\}) \cup \{1,\ldots,\bar{x}\},$$

so that the assumption $x \in \{1,\ldots,m\}$ implies

$$x \in \{1,\ldots,\bar{x}\} \ \vee \ x \in \{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\} \tag{4.482}$$

with the definition of the union of two sets and the Commutative Law for the disjunction. We now use this true disjunction to prove the existential part regarding the uniquely existential sentence in (4.481) by cases.

On the one hand, if $x \in \{1,\ldots,\bar{x}\}$ is true, we observe that $\{1,\ldots,m\} \subset \{1,\ldots,m^+\}$ holds with (4.254), so that $\{1,\ldots,m\} \subseteq \{1,\ldots,m^+\}$ follows to be true with (2.26). Therefore, the assumed $x \in \{1,\ldots,m\}$ implies $x \in \{1,\ldots,m^+\}$ by definition of a subset, which shows that x is an element of the domain of the function f. Consequently, the function value $\bar{y} = f(x)$ exists, so that the implication

$$x \in \{1,\ldots,\bar{x}\} \ \Rightarrow \ \bar{y} = f(x) \tag{4.483}$$

is true (since both the antecedent and the consequent are true). Furthermore, as $x \in \{1,\ldots,\bar{x}\}$ was assumed to be true, the negation $x \notin \{1,\ldots,\bar{x}\}$ is false, and therefore the conjunction of $x \in \{1,\ldots,m\}$ and $x \notin \{1,\ldots,\bar{x}\}$ is also false, which shows in light of the definition of a set difference that the antecedent of the implication

$$x \in \{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\} \ \Rightarrow \ \bar{y} = f(x^+) \tag{4.484}$$

is false. Thus, the implications (4.483) and (4.484) are both true in the first case.

On the other hand, if the second part $x \in \{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\}$ of the disjunction (4.482) is true, we have in particular $x \in \{1,\ldots,m\}$, which implies $x \leq m$ with (4.275) and therefore also $x^+ \leq m^+$ with (4.273). This finding further implies

$$x^+ \in \{1,\ldots,m^+\} \tag{4.485}$$

again with (4.275), so that x^+ is an element of the domain of f. Consequently, the function value $\bar{y} = f(x^+)$ exists, and the truth of this equation and of the current case assumption clearly shows that the implication (4.484) is true for $\bar{y} = f(x^+)$. Since the case assumption implies (with the definition of a set difference) in particular that $x \in \{1,\ldots,\bar{x}\}$ is false, we see that the implication (4.483) – being based on a false antecedent – is true for $\bar{y} = f(x^+)$ as well.

Thus, there exists in any case a constant y which satisfies the conjunction of the two implications in (4.481), so that the proof of the existential part by cases is complete. Regarding the uniqueness part, we let y and y' be arbitrary constants satisfying that conjunction of implications, and we prove $y = y'$ by cases, based on the true disjunction (4.482).

On the one hand, if $x \in \{1, \ldots, \bar{x}\}$ holds, then the true implications

$$x \in \{1, \ldots, \bar{x}\} \Rightarrow y = f(x)$$
$$x \in \{1, \ldots, \bar{x}\} \Rightarrow y' = f(x)$$

give $y = f(x)$ and $y' = f(x)$, so that the desired $y = y'$ follows via substitution.

On the other hand, if $x \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\}$ holds, then the other two true implications

$$x \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\} \Rightarrow y = f(x^+)$$
$$x \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\} \Rightarrow y' = f(x^+)$$

yield $y = f(x^+)$ and $y' = f(x^+)$, so that $y = y'$ follows again to be true. This completes the proof of the uniqueness part by cases, and the resulting truth of the uniquely existential sentence in (4.481) proves in turn the implication based on the antecedent $x \in \{1, \ldots, m\}$. Since x was arbitrary, we may therefore conclude that the universal sentence (4.481) holds, which then implies with Theorem 3.160 that there exists a unique function g with domain $\{1, \ldots, m\}$ such that $g(x) = f(x)$ holds for any $x \in \{1, \ldots, \bar{x}\}$ and such that $g(x) = f(x^+)$ holds for any $x \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\}$. We thus obtained the mapping (4.480).

We now demonstrate that $\{1, \ldots, n\}$ is a codomain of g, i.e. that $\mathrm{ran}(g) \subseteq \{1, \ldots, n\}$ holds. To do this, we apply the definition of a subset and verify

$$\forall y\, (y \in \mathrm{ran}(g) \Rightarrow y \in \{1, \ldots, n\}). \tag{4.486}$$

We let y be an arbitrary element of the range of g, so that there exists (by definition of a range) a particular constant $\bar{\bar{x}}$ with $(\bar{\bar{x}}, y) \in g$, which we may also write as $g(\bar{\bar{x}}) = y$ and which shows (in view of the definition of a domain) that $\bar{\bar{x}} \in \{1, \ldots, m\}$ [$= \mathrm{dom}(g)$] holds. We may now apply exactly the same line of arguments used earlier for establishing (4.482) to infer from $\bar{\bar{x}} \in \{1, \ldots, m\}$ the truth of the disjunction

$$\bar{\bar{x}} \in \{1, \ldots, \bar{x}\} \vee \bar{\bar{x}} \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\}. \tag{4.487}$$

Let us now prove the sentence $g(\bar{\bar{x}}) \in \{1, \ldots, n\}$ by cases by using this disjunction.

On the one hand, if $\bar{\bar{x}} \in \{1, \ldots, \bar{x}\}$ holds, then we obtain $\bar{\bar{x}} \leq \bar{x}$ with (4.275), where $\bar{x} < \bar{x}^+$ holds according to (4.153). The previous two inequalities imply $\bar{\bar{x}} < \bar{x}^+$ with the Transitivity Formula for $\leq$ and $<$, so that $\bar{\bar{x}} \neq \bar{x}^+$ is true due to the comparability of $<$. Moreover, in view of the previously established inclusions $\{1, \ldots, \bar{x}\} \subseteq \{1, \ldots, m\} \subseteq \{1, \ldots, m^+\}$, we see that the current case assumption $\bar{\bar{x}} \in \{1, \ldots, \bar{x}\}$ yields $\bar{\bar{x}} \in \{1, \ldots, m^+\}$ with the transitivity of $\subseteq$ and the definition of a subset. Thus, $\bar{\bar{x}}$ is an element of the domain $\{1, \ldots, m^+\}$ of f, and the conjunction of $\bar{\bar{x}} \in \{1, \ldots, m^+\}$ and $\bar{\bar{x}} \neq \bar{x}^+$ is true, which implies $n^+ \neq f(\bar{\bar{x}})$ with (4.479), and therefore $f(\bar{\bar{x}}) \notin \{n^+\}$ with (2.169). As $\{1, \ldots, n^+\}$ was assumed to be the codomain of f, we therefore have the conjunction

$$f(\bar{\bar{x}}) \in \{1, \ldots, n^+\} \wedge f(\bar{\bar{x}}) \notin \{n^+\}.$$

By definition of a set difference, this means $f(\bar{\bar{x}}) \in \{1, \ldots, n^+\} \setminus \{n^+\}$, which then yields $f(\bar{\bar{x}}) \in \{1, \ldots, n\}$ with (4.256). Since $\bar{\bar{x}} \in \{1, \ldots, \bar{x}\}$ implies $g(\bar{\bar{x}}) = f(\bar{\bar{x}})$ by definition of the function g, we obtain the desired $g(\bar{\bar{x}}) \in \{1, \ldots, n\}$ via substitution.

On the other hand, if $\bar{\bar{x}} \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\}$ holds, then we have $\bar{\bar{x}} \notin \{1, \ldots, \bar{x}\}$ (by definition of a set difference), and we therefore obtain $\neg \bar{\bar{x}} \leq \bar{x}$ with (4.275), so that $\bar{x} < \bar{\bar{x}}$ follows to be true with the Negation Formula for $\leq$. The latter inequality implies $\bar{x} \neq \bar{\bar{x}}$ with the comparability of $<$, which finding then further implies $\bar{x}^+ \neq \bar{\bar{x}}^+$ with (4.128) and the Law of Contraposition. We may now infer from the current case assumption the truth of $\bar{\bar{x}}^+ \in \{1, \ldots, m^+\}$ by applying the same arguments that we used in the course of establishing (4.485). Thus, the conjunction of $\bar{\bar{x}}^+ \in \{1, \ldots, m^+\}$ and $\bar{\bar{x}}^+ \neq \bar{x}^+$ is true, and this conjunction implies $n^+ \neq f(x^+)$ with (4.479); consequently, $f(\bar{\bar{x}}^+) \notin \{n^+\}$ follows to be true with (2.169). Recalling that $\{1, \ldots, n^+\}$ is the codomain of f, we therefore have the true conjunction

$$f(\bar{\bar{x}}^+) \in \{1, \ldots, n^+\} \wedge f(\bar{\bar{x}}^+) \notin \{n^+\},$$

which evidently yields $f(\bar{\bar{x}}^+) \in \{1, \ldots, n^+\} \setminus \{n^+\}$ and therefore $f(\bar{\bar{x}}^+) \in \{1, \ldots, n\}$. As the case assumption $\bar{\bar{x}} \in \{1, \ldots, m\} \setminus \{1, \ldots, \bar{x}\}$ implies $g(\bar{\bar{x}}) = f(x^+)$ by definition of g, we obtain again $g(\bar{\bar{x}}) \in \{1, \ldots, n\}$, completing the proof by cases.

Recalling the equation $g(\bar{\bar{x}}) = y$, we thus showed that $y \in \operatorname{ran}(g)$ implies $y \in \{1, \ldots, n\}$. As y was arbitrary, we may therefore conclude that (4.486) holds, so that $\{1, \ldots, n\}$ constitutes indeed a codomain of g. We thus showed that g is a function from $\{1, \ldots, m\}$ to $\{1, \ldots, n\}$, and we now demonstrate that – as a consequence of this finding – the assumed function

$f:\{1,\ldots,m^+\}\to\{1,\ldots,n^+\}$ is not an injection. To begin with, the initial assumption $n\in\mathbb{N}_+$ implies $1\le n$ with (4.278), which gives – together with the previously established $n<m$ – the inequality $1<m$ by applying the Transitivity Formula for $\le$ and $<$. This inequality yields $1\neq m$ with the comparability of $<$, so that there exists because of 4.229 an element $\bar{k}$ in $\mathbb{N}_+$ (and thus in $\mathbb{N}$) such that $\bar{k}^+=m$. Thus, $\bar{k}\in\mathbb{N}$, $n<\bar{k}^+$ and $g\in\{1,\ldots,n\}^{\{1,\ldots,\bar{k}^+\}}$ are true, so that g is not an injection because of the induction assumption (4.475). Consequently, there exist because of Exercise 3.77 elements of the domain of g, say $\bar{x}',\bar{x}''\in\{1,\ldots,m\}$, such that the conjunction

$$\bar{x}'\neq\bar{x}''\ \wedge\ g(\bar{x}')=g(\bar{x}'') \tag{4.488}$$

holds. To prove that $f:\{1,\ldots,m^+\}\to\{1,\ldots,n^+\}$ is not an injection, we verify

$$\exists x,x'\,(x,x'\in\{1,\ldots,m^+\}\ \wedge\ x\neq x'\ \wedge\ f(x)=f(x')) \tag{4.489}$$

according to (3.620). We notice that $\bar{x}',\bar{x}''\in\{1,\ldots,m\}$ implies the truth of the disjunctions

$$\bar{x}'\in\{1,\ldots,\bar{x}\}\ \vee\ \bar{x}'\in\{1,\ldots,m\}\setminus\{1,\ldots,\bar{x}\} \tag{4.490}$$

$$\bar{x}''\in\{1,\ldots,\bar{x}\}\ \vee\ \bar{x}''\in\{1,\ldots,m\}\setminus\{1,\ldots,\bar{x}\} \tag{4.491}$$

and of $\bar{x}'^+,\bar{x}''^+\in\{1,\ldots,m^+\}$ for the same reasons as the selection of an arbitrary $x\in\{1,\ldots,m\}$ implied, respectively, (4.482) and (4.485). It will also be useful to apply the previously mentioned inclusion $\{1,\ldots,m\}\subseteq\{1,\ldots,m^+\}$ (in connection with the definition of a subset) to infer from the assumed $\bar{x}',\bar{x}''\in\{1,\ldots,m\}$ the truth of $\bar{x}',\bar{x}''\in\{1,\ldots,m^+\}$. Thus, the constants $\bar{x}'$ and $\bar{x}''$ are also elements of the domain of f, as required within the proof of the non-injectivity of f based on (4.489). We now prove that existential sentence by cases, using first the true disjunction (4.490).

If $\bar{x}'\in\{1,\ldots,\bar{x}\}$ holds, then the definition of g yields $g(\bar{x}')=f(\bar{x}')$. We now include another proof by cases (of the desired existential sentence) based on the other true disjunction (4.491). On the one hand, in case $\bar{x}''\in\{1,\ldots,\bar{x}\}$ holds, which evidently yields $g(\bar{x}'')=f(\bar{x}'')$, we obtain with the equation in (4.488) after substitution $f(\bar{x}')=f(\bar{x}'')$. In view of the previously established $\bar{x}',\bar{x}''\in\{1,\ldots,m^+\}$ and in view of the inequality in (4.488), we thus see that the conjunction

$$\bar{x}',\bar{x}''\in\{1,\ldots,m^+\}\ \wedge\ \bar{x}'\neq\bar{x}''\ \wedge\ f(\bar{x}')=f(\bar{x}'') \tag{4.492}$$

is true, so that the existential sentence (4.489) to be proven holds indeed. On the other hand, the case $\bar{x}''\in\{1,\ldots,m\}\setminus\{1,\ldots,\bar{x}\}$ yields $g(\bar{x}'')=$

$f(\bar{x}''^{+})$ by definition of g, and we obtain therefore with the equation in (4.488) via substitution $f(\bar{x}') = f(\bar{x}''^{+})$. Furthermore, $\bar{x}'' \in \{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\}$ implies $\bar{x}'' \notin \{1,\ldots,\bar{x}\}$ (by definition of a set difference) and therefore $\bar{x}''^{+} \notin \{1,\ldots,\bar{x}\}$ with (4.249) and the Law of Contraposition. Thus, the conjunction of $\bar{x}' \in \{1,\ldots,\bar{x}\}$ and $\bar{x}''^{+} \notin \{1,\ldots,\bar{x}\}$ is true, which yields $\bar{x}' \neq \bar{x}''^{+}$ with Proposition 2.1. Recalling $\bar{x}' \in \{1,\ldots,m^{+}\}$ and $\bar{x}''^{+} \in \{1,\ldots,m^{+}\}$, these findings show that the conjunction

$$\bar{x}', \bar{x}''^{+} \in \{1,\ldots,m^{+}\} \wedge \bar{x}' \neq \bar{x}''^{+} \wedge f(\bar{x}') = f(\bar{x}''^{+}) \tag{4.493}$$

is true, and consequently the existential sentence (4.489) holds again. Thus, the proof by cases based on the disjunction (4.491) is complete.

If $\bar{x}' \in \{1,\ldots,m\}\setminus\{1,\ldots,\bar{x}\}$ holds, then the definition of g yields $g(\bar{x}') = f(\bar{x}'^{+})$. Let us consider once again the two cases of the disjunction (4.491). On the one hand, if $\bar{x}'' \in \{1,\ldots,\bar{x}\}$ holds, which yields $g(\bar{x}'') = f(\bar{x}'')$ by definition of g, then we obtain with the equation in (4.488) $f(\bar{x}'^{+}) = f(\bar{x}'')$. Moreover, $\bar{x}' \in \{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\}$ gives $\bar{x}' \notin \{1,\ldots,\bar{x}\}$ (by definition of a set difference) and then $\bar{x}'^{+} \notin \{1,\ldots,\bar{x}\}$ with (4.249) and the Law of Contraposition. As $\bar{x}'' \in \{1,\ldots,\bar{x}\}$ and $\bar{x}'^{+} \notin \{1,\ldots,\bar{x}\}$ are thus both true, it follows that $\bar{x}'' \neq \bar{x}'^{+}$ (using again Proposition 2.1). We therefore have the true conjunction

$$\bar{x}'', \bar{x}'^{+} \in \{1,\ldots,m^{+}\} \wedge \bar{x}'' \neq \bar{x}'^{+} \wedge f(\bar{x}'') = f(\bar{x}'^{+}), \tag{4.494}$$

so that the existential sentence (4.489) holds, as desired. On the other hand, if $\bar{x}'' \in \{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\}$ holds, which gives $g(\bar{x}'') = f(\bar{x}''^{+})$ by definition of g, then we obtain with the equation in (4.488) $f(\bar{x}'^{+}) = f(\bar{x}''^{+})$. Due to the inequality in (4.488), we see that $\bar{x}'$ and $\bar{x}''$ are distinct elements of the same set $\{1,\ldots,m\} \setminus \{1,\ldots,\bar{x}\}$. The preceding inequality $\bar{x}' \neq \bar{x}''$ then implies $s^{+}(\bar{x}') \neq s^{+}(\bar{x}'')$ with the Injection Criterion (recalling that the successor function is an injection), which inequality we may write also as $\bar{x}'^{+} \neq \bar{x}''^{+}$. Therefore, the conjunction

$$\bar{x}'^{+}, \bar{x}''^{+} \in \{1,\ldots,m^{+}\} \wedge \bar{x}'^{+} \neq \bar{x}''^{+} \wedge f(\bar{x}'^{+}) = f(\bar{x}''^{+}) \tag{4.495}$$

is now true, so that the existential sentence (4.489) holds in any case.

This completes the proof that f is not an injection for the case that the negation of (4.478) is true. We thus completed also the proof that f is not an injection if the second part $\neg\mathrm{ran}(f) \subseteq \{1,\ldots,n\}$ of the disjunction (4.477) holds. Since f is arbitrary, we may therefore conclude that the universal sentence with respect to f in (4.476) is true. Because m is also arbitrary, we may now further conclude that the universal sentence (4.476) holds. Then, as n was arbitrary as well, we may finally conclude that the induction step is true (besides the base case), which completes the proof of (4.472) by mathematical induction, and thus also the proof of the proposed sentence (4.471). □

Exercise 4.35. Show that (4.471) also holds for $n = 0$, that is,

$$\forall m, n\,([m \in \mathbb{N} \wedge n = 0] \Rightarrow$$
$$[n < m^+ \Rightarrow \neg\exists f\,(f \in \{1, \ldots, n\}^{\{1,\ldots,m^+\}} \wedge f \text{ is an injection})]). \quad (4.496)$$

(Hint: Apply first Method 1.6 and then Method 1.11, using (3.528).)

Theorem 4.102 (Dirichlet's Drawer Principle/Pigeonhole Principle). *For any natural numbers m and n, it is true that there is no injection from the initial segment $\{1, \ldots, m\}$ to the initial segment $\{1, \ldots, n\}$ if n is less than m, that is,*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [n < m \Rightarrow \neg\exists f\,(f : \{1, \ldots, m\} \hookrightarrow \{1, \ldots, n\})]). \quad (4.497)$$

Proof. Letting m and n be arbitrary, we assume first $m, n \in \mathbb{N}$ and subsequently also $n < m$ to be true. Since $0 \leq n$ also holds according to (4.187), we obtain with the Transitivity Formula for $\leq$ and $<$ the inequality $0 < n$ and therefore $n \neq 0$ with the comparability of the linear ordering $<$ of $\mathbb{N}$. It then follows from this with (4.39) that there exists a particular constant $\bar{k} \in \mathbb{N}$ with $\bar{k} \neq m$ and $\bar{k}^+ = m$. Thus, the initial assumption $n < m$ yields $n < \bar{k}^+$ via substitution. Furthermore, we see in light of (2.310) that the disjunction $n = 0 \vee n \in \mathbb{N}_+$ is true, which we now use to prove the sentence

$$\neg\exists f\,(f : \{1, \ldots, \bar{k}^+\} \hookrightarrow \{1, \ldots, n\}) \quad (4.498)$$

by cases. If $n = 0$ holds, then (4.498) follows from $n < \bar{k}^+$ with (4.496), and if $n \in \mathbb{N}_+$ holds, we obtain (4.498) with (4.471). Thus, the negated existential sentence in (4.497) is also true, because we may simply substitute m for $\bar{k}^+$ in (4.498). Since m and n were initially arbitrary, we may therefore conclude that the universal sentence (4.497) is true. □

Note 4.19. According to (4.260), the inequality $n < m$ is equivalent to $\{1, \ldots, n\} \subset \{1, \ldots, m\}$. Dirichlet's Drawer Principle thus shows that it is not possible that distinct elements of the domain of a function are always associated with distinct values if the range is a proper subset of the domain. This finding may be viewed as a mathematical analogue to the observable fact that a collection of objects/pigeons cannot be put into different drawers/holes if there are 'less drawers/holes than objects/pigeons'.

Before we can use the length n of a denumeration of a given (finite) set A as a valid counting of the number of elements in A, we must show that all other possible denumerations of A have the same length n.

Theorem 4.103 (Denumeration theorem). *For any finite set A the length of any denumeration of A is unique, that is,*

$$\forall A\,(A \text{ is a finite set } \Rightarrow\ \exists! n\,(n \in \mathbb{N} \wedge \exists c\,(c : \{1,\dots,n\} \rightleftarrows A))). \tag{4.499}$$

Proof. We let A be an arbitrary set, assume A to be finite, and observe that the existential part

$$\exists n\,(n \in \mathbb{N} \wedge \exists c\,(c : \{1,\dots,n\} \rightleftarrows A))$$

of the uniquely existential sentence is equivalent to

$$\exists n\,\exists c\,(n \in \mathbb{N} \wedge c : \{1,\dots,n\} \rightleftarrows A)$$

because of the Neutrality Law for quantification (1.57), which is then true by definition of a finite set. To verify the uniqueness part, we prove

$$\begin{aligned}\forall n, n'\,([(n \in \mathbb{N} \wedge \exists c\,(c : \{1,\dots,n\} \rightleftarrows A))\\ \wedge\ (n' \in \mathbb{N} \wedge \exists c\,(c : \{1,\dots,n'\} \rightleftarrows A))] \Rightarrow n = n').\end{aligned} \tag{4.500}$$

For this purpose, we let n and n' be arbitrary and prove the implication directly, assuming that n and n' are natural numbers, assuming that there exists a bijection from $\{1,\dots,n\}$ to A, say

$$\bar{c} : \{1,\dots,n\} \rightleftarrows A,$$

and assuming moreover that there exists a bijection from $\{1,\dots,n'\}$ to A, say

$$\bar{c}' : \{1,\dots,n'\} \rightleftarrows A.$$

Then, the corresponding inverse functions are also bijections because of (3.683), that is,

$$\begin{aligned}\bar{c}^{-1} &: A \rightleftarrows \{1,\dots,n\},\\ \bar{c}'^{-1} &: A \rightleftarrows \{1,\dots,n'\}.\end{aligned}$$

It then follows with (3.672) that the compositions $\bar{c}'^{-1} \circ \bar{c}$ and $\bar{c}^{-1} \circ \bar{c}'$ are the bijections

$$\begin{aligned}\bar{c}'^{-1} \circ \bar{c} &: \{1,\dots,n\} \rightleftarrows \{1,\dots,n'\},\\ \bar{c}^{-1} \circ \bar{c}' &: \{1,\dots,n'\} \rightleftarrows \{1,\dots,n\}.\end{aligned}$$

These compositions are thus in particular injections, which shows that the existential sentence

$$\exists f\,(f : \{1,\ldots,n\} \hookrightarrow \{1,\ldots,n'\}), \tag{4.501}$$
$$\exists f\,(f : \{1,\ldots,n'\} \hookrightarrow \{1,\ldots,n\}). \tag{4.502}$$

are true. Now, since the standard linear ordering $<$ of $\mathbb{N}$ is connex, the disjunction

$$n < n' \lor n' < n \lor n = n' \tag{4.503}$$

is true. We may now prove by contradiction that $\neg n < n'$ is true. For this purpose, we assume the negation of that negation to be true, so that $n < n'$ follows to be true with the Double Negation Law. It then follows with (4.497) that the negation of (4.502) is also true, so that we obtained a contradiction. Thus, $\neg n < n'$ is indeed true.

On the other hand, we may prove by contradiction that $\neg n' < n$ holds. To do this, we assume the double negation to be true, so that $n' < n$ follows now to be true. We then see in light of Dirichlet's Drawer Principle that the negation of (4.501) turns out to be true as well. Thus, we have a contradiction again, so that $\neg n' < n$ is also true (besides $\neg n < n'$).

Consequently, the third part $n = n'$ of the true disjunction (4.503) holds, which finding completes the direct proof of the implication in (4.500). As n and n' are arbitrary, we may therefore conclude that the universal sentence (4.500) is true, completing the proof of the uniquely existential sentence in (4.499). Since A was initially an arbitrary set, we now finally conclude that the theorem holds, as claimed. □

This unique length of the denumerations of a given (finite) set A is defined to be its *number of elements*.

Definition 4.11 (Cardinality/number of elements). For any finite set A we say that a natural number n is the *cardinality* or the *number of elements* of A, symbolically

$$n = |A|, \tag{4.504}$$

iff there exists a denumeration of A of length n, i.e. iff

$$\exists c\,(c : \{1,\ldots,n\} \rightleftarrows A) \tag{4.505}$$

Corollary 4.104. *The initial segment of* $\mathbb{N}_+$ *up to an* $n \in \mathbb{N}$ *has* n *elements, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow |\{1,\ldots,n\}| = n). \tag{4.506}$$

Proof. Letting n be arbitrary in $\mathbb{N}$, we see that the identity function $\mathrm{id}_{\{1,\ldots,n\}}$ is a bijection from $\{1,\ldots,n\}$ to $\{1,\ldots,n\}$ due to Corollary 3.203, so that there exists a denumeration of $\{1,\ldots,n\}$ of length n. Consequently, $n = |\{1,\ldots,n\}|$ holds by definition of a cardinality, which equation proves the implication in (4.506), and since n was initially arbitrary, we may therefore conclude that the proposed universal sentence holds. $\square$

Note 4.20. In case of $m = 0$, we have $\{1,\ldots,m\} = \emptyset$, and we may view $\mathrm{id}_{\{1,\ldots,m\}}$ as the empty bijection $\emptyset : \emptyset \rightleftarrows \emptyset$.

The following result is an immediate consequence of the proof of Proposition 4.99, which involves the existence of the bijections (4.468) and (4.469).

Corollary 4.105. *The union of a finite set A with cardinality $\bar{n}$ and the singleton formed by a constant y which is not in A is a finite set with cardinality $\bar{n}^+$, that is,*

$$\forall A, y, \bar{n}\,([y \notin A \,\wedge\, A \text{ is finite } \wedge\, |A| = \bar{n}] \\ \Rightarrow [A \cup \{y\} \text{ is finite } \wedge\, |A \cup \{y\}| = \bar{n}^+]). \tag{4.507}$$

Proposition 4.106. *The Cartesian product of the initial segment of $\mathbb{N}_+$ up to a natural number m and the singleton formed by a natural number n has cardinality m, that is,*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow |\{1,\ldots,m\} \times \{n\}| = m). \tag{4.508}$$

Proof. We let m and n be arbitrary natural numbers and show that there exists a denumeration c from $\{1,\ldots,m\}$ to $\{1,\ldots,m\} \times \{n\}$. First, we apply Function definition by replacement and verify for this purpose

$$\forall k\,(k \in \{1,\ldots,m\} \Rightarrow \exists! y\,(y = (k, n))). \tag{4.509}$$

Letting k be arbitrary, we assume $k \in \{1,\ldots,m\}$ to be true. By definition of an ordered pair, (k, n) is a uniquely specified set, so that the uniquely existential sentence in (4.509) follows to be true with (1.109). Since k is arbitrary, we may therefore conclude that the universal sentence (4.509) holds, which then further implies with Theorem 3.160 that there exists the unique function $\bar{c}$ with domain $\{1,\ldots,m\}$ satisfying

$$\forall k\,(k \in \{1,\ldots,m\} \Rightarrow \bar{c}(k) = (k, n)). \tag{4.510}$$

Next, we show that $\bar{c}$ is a bijection from $\{1,\ldots,m\}$ to $\{1,\ldots,m\} \times \{n\}$. To prove that $\bar{c}$ is a surjection from $\{1,\ldots,m\}$ to $\{1,\ldots,m\} \times \{n\}$, we demonstrate that $\{1,\ldots,m\} \times \{n\}$ is the range of $\bar{c}$ by verifying

$$\forall y\,(y \in \{1,\ldots,m\} \times \{n\} \Rightarrow \exists k\,(k \in \{1,\ldots,m\} \,\wedge\, \bar{c}(k) = y)). \tag{4.511}$$

according to the Surjection Criterion. We let y be arbitrary and assume $y \in \{1, \ldots, m\} \times \{n\}$ to be true. By definition of the Cartesian product of two sets, there then exists an element in $\{1, \ldots, m\}$, say $\bar{k}$, and there exists the unique element n in $\{n\}$ (according to Exercise 2.20), such that $(\bar{k}, n) = y$. Here, $\bar{k} \in \{1, \ldots, m\}$ implies $\bar{c}(\bar{k}) = (\bar{k}, n) \, [= y]$ with (4.510), which equations yield $\bar{c}(\bar{k}) = y$. We thus showed that the existential sentence in (4.511) holds, which proves the implication in (4.511). As y is arbitrary, we may therefore conclude that the universal sentence (4.511) holds. We thus showed that $\bar{c}$ is a surjection from $\{1, \ldots, m\}$ to $\{1, \ldots, m\} \times \{n\}$.

It remains for us to verify that $\bar{c}$ is also an injection from $\{1, \ldots, m\}$ to $\{1, \ldots, m\} \times \{n\}$. For this purpose, we prove

$$\forall k, k' \, ([k, k' \in \{1, \ldots, m\} \wedge \bar{c}(k) = \bar{c}(k')] \Rightarrow k = k'). \tag{4.512}$$

Letting k and k' be arbitrary in $\{1, \ldots, m\}$ such that $\bar{c}(k) = \bar{c}(k')$ holds, we infer from the latter equation with (4.510) that $(k, n) = (k', n)$ is true. This equation implies in particular $k = k'$ with the Equality Criterion for ordered pairs, and since k, k' are arbitrary, it follows then that the universal sentence (4.512) holds. Thus, the surjection $\bar{c} : \{1, \ldots, m\} \twoheadrightarrow \{1, \ldots, m\} \times \{n\}$ is also an injection, and therefore a bijection by definition. Because m is a natural number, the existence of this denumeration then evidently gives

$$m = |\{1, \ldots, m\} \times \{n\}|,$$

in view of the definition of a cardinality, proving the implication in (4.508). As m and n were arbitrary, we may consequently conclude that the proposed universal sentence is true. □

The notion of *number of elements* of a set suggests the following terminology.

Definition 4.12 (Equinumerous/equivalent finite sets). We say that two finite sets A and B are *equinumerous* or *equivalent* iff they have the same number of elements, i.e. iff

$$|A| = |B|. \tag{4.513}$$

The idea of counting a finite set via a bijective association/comparison with an initial segment of $\mathbb{N}_+$ is now generalized to compare any two given sets with respect to their number of elements.

Proposition 4.107. *Two finite sets A and B are equinumerous iff there exists a one-to-one correspondence from A to B, that is,*

$$\forall A, B \, (|A| = |B| \;\Leftrightarrow\; \exists f \, (f : A \rightleftarrows B)). \tag{4.514}$$

Proof. We let A and B arbitrary sets and assume A and B to be finite, so that there exist natural numbers, say $\bar{m}$ and $\bar{n}$, and denumerations of A and B of length $\bar{m}$ and $\bar{n}$, respectively, say

$$\begin{aligned} \bar{c} &: \{1,\dots,\bar{m}\} \rightleftarrows A, \\ \bar{d} &: \{1,\dots,\bar{n}\} \rightleftarrows B. \end{aligned} \tag{4.515}$$

These denumerations give the cardinalities $\bar{m} = |A|$ and $\bar{n} = |B|$. To prove the first implication ($\Rightarrow$), we assume $|A| = |B|$, so that substitution yields first $\bar{m} = \bar{n}$ and then

$$\bar{c} : \{1,\dots,\bar{n}\} \rightleftarrows A.$$

Because of (3.683), we obtain the inverse bijection

$$\bar{c}^{-1} : A \rightleftarrows \{1,\dots,\bar{n}\},$$

and (3.672) gives then the bijective composition

$$\bar{d} \circ \bar{c}^{-1} : A \rightleftarrows B,$$

so that the existential sentence in (4.514) is true, as desired.

To prove the second implication ($\Leftarrow$), we assume the preceding existential sentence to be true and take in particular $\bar{f} : A \rightleftarrows B$. Then, we may form the composition of $\bar{f}$ and (4.515), which is the bijection $\bar{f} \circ \bar{c} : \{1,\dots,\bar{m}\} \rightleftarrows B$ according to (3.672). This bijection is a denumeration of B of length $\bar{m}$, so that $\bar{m} = |B|$ holds. Since $\bar{m} = |A|$ is also true, we may apply substitution to obtain the desired equation $|A| = |B|$.

Thus, the proof of the equivalence is complete, and since A and B were arbitrary sets, we may therefore conclude that the proposition holds. □

Definition 4.13 (Permutation). For any finite set X we call any one-to-one correspondence

$$\pi : X \rightleftarrows X \tag{4.516}$$

a *permutation of* X.

Note 4.21. Permutations are invertible transformations, so that the set of all permutations of a (finite) set X is a more specific set of invertible transformations. In contrast to a permutation, the domain of an invertible transformation may be an infinite set.

Definition 4.14 (Set of permutations). We call the set of invertible transformations on any finite set X also the *set of permutations* of X, symbolically

$$\Pi(X). \tag{4.517}$$

Note 4.22. As identity functions are bijective (see Corollary 3.203), the identity function on any finite set constitutes a permutation of that set.

Corollary 4.108. *Any natural number n and the initial segment of $\mathbb{N}_+$ up to n are equinumerous sets, that is,*

$$|n| = |\{1, \ldots, n\}|, \tag{4.518}$$

$$|\{1, \ldots, n\}| = |n|. \tag{4.519}$$

Furthermore, the cardinality of a natural number n is identical with n, i.e.

$$\forall n \, (n \in \mathbb{N} \Rightarrow |n| = n). \tag{4.520}$$

Proof. Letting n be an arbitrary natural number, the existence of the bijections (4.465) and (4.466) prove (4.518) and (4.519), respectively. Since $|\{1, \ldots, n\}| = n$ holds according to (4.506), the equation (4.518) yields $|n| = n$ via substitution. Since n is arbitrary, the stated universal sentences follow then to be true. □

Proposition 4.109. *The Cartesian product of a finite set A and a singleton is itself finite, and this Cartesian product and the set A are equinumerous, that is,*

$$\forall A, a \, (A \text{ is finite } \Rightarrow [A \times \{a\} \text{ is finite } \wedge \, |A \times \{a\}| = |A|]). \tag{4.521}$$

Proof. Letting A and a be arbitrary, we first establish a bijection c from A to $A \times \{a\}$. To begin with, we introduce the notation $B = A \times \{a\}$ and then apply the Axiom of Specification in connection with the Axiom of Extension to obtain the true uniquely existential sentence

$$\exists! \bar{c} \forall z \, (z \in \bar{c} \Leftrightarrow [z \in A \times (A \times \{a\}) \, \wedge \, \exists x \, (z = (x, (x, a)))]).$$

Thus, $z \in \bar{c}$ implies in particular $z \in A \times (A \times \{a\})$ for any z, so that $\bar{c}$ may be viewed as a binary relation included in $A \times B$ (applying the definitions of a binary relation and of a subset). This binary relation $\bar{c}$ thus satisfies

$$\forall z \, (z \in \bar{c} \Leftrightarrow [z \in A \times (A \times \{a\}) \, \wedge \, \exists x \, (z = (x, (x, a)))]). \tag{4.522}$$

We now demonstrate that $\bar{c}$ is a function from A to $A \times \{a\}$. To do this, we apply the Function Criterion and verify accordingly

$$\forall x \, (x \in A \Rightarrow \exists! y \, (y \in A \times \{a\} \, \wedge \, (x, y) \in \bar{c})). \tag{4.523}$$

We let $\bar{x} \in A$ be arbitrary and prove first the existential part of the uniquely existential sentence with respect to y. Since $a \in \{a\}$ is evidently true and since the ordered pair $\bar{y} = (\bar{x}, a)$ is uniquely specified, we see that there exist x and b such that $x \in A$, $b \in \{a\}$ and $(x, b) = \bar{y}$ are true. It then follows with the definition of the Cartesian product of two sets that $\bar{y} \in A \times \{a\}$ holds. Furthermore, the ordered pair

$$\bar{z} = (\bar{x}, \bar{y}) = (\bar{x}, (\bar{x}, a))$$

is uniquely specified, which equations show that there exists an x with $\bar{z} = (x, (x, a))$. We also see that there exist x and y with $x \in A$, $y \in A \times \{a\}$ and $(x, y) = \bar{z}$, which implies (again by definition of the Cartesian product of two sets) that $\bar{z} \in A \times (A \times \{a\})$ holds. It then follows from these findings with (4.522) that $[(\bar{x}, \bar{y}) =]\ \bar{z} \in \bar{c}$ is true, which gives $(\bar{x}, \bar{y}) \in \bar{c}$. Together with the previously established $\bar{y} \in A \times \{a\}$, this proves the existential part in (4.523). To prove the uniqueness part, we verify

$$\forall y, y' \, ([y \in A \times \{a\} \wedge (\bar{x}, y) \in \bar{c} \wedge y' \in A \times \{a\} \wedge (\bar{x}, y') \in \bar{c}] \Rightarrow y = y'). \tag{4.524}$$

We let $\bar{y}$ and $\bar{y}'$ be arbitrary in $A \times \{a\}$ such that $(\bar{x}, \bar{y})$ and $(\bar{x}, \bar{y}')$ are elements of $\bar{c}$. Here, $(\bar{x}, \bar{y}) \in \bar{c}$ implies with (4.522) in particular that there exists an element, say $\bar{\bar{x}}$, with $(\bar{x}, \bar{y}) = (\bar{\bar{x}}, (\bar{\bar{x}}, a))$; this equation gives $\bar{x} = \bar{\bar{x}}$ and $\bar{y} = (\bar{\bar{x}}, a)$ with (3.3), so that substitution yields $\bar{y} = (\bar{x}, a)$. Similarly, $(\bar{x}, \bar{y}') \in \bar{c}$ implies in particular that there is an element, say $\bar{\bar{x}}'$, with $(\bar{x}, \bar{y}') = (\bar{\bar{x}}', (\bar{\bar{x}}', a))$; consequently, $\bar{x} = \bar{\bar{x}}'$ and $\bar{y}' = (\bar{\bar{x}}', a)$, so that

$$\bar{y}' = (\bar{x}, a) \quad [= \bar{y}].$$

These equations yield $\bar{y} = \bar{y}'$, and since $\bar{y}$ and $\bar{y}'$ were arbitrary, we may therefore conclude that (4.524) holds, completing the proof of the uniquely existential sentence in (4.523). As x was arbitrary, we may then further conclude that (4.523) is true, which proves due to the Function Criterion that $\bar{c}$ is a function from A to $A \times \{a\}$.

Next, we show that $\bar{c}$ is a surjection, i.e. that $\mathrm{ran}(\bar{c}) = A \times \{a\}$ holds. To do this, we verify $A \times \{a\} \subseteq \mathrm{ran}(\bar{c})$ first, i.e. (using the definition of a subset)

$$\forall y \, (y \in A \times \{a\} \Rightarrow y \in \mathrm{ran}(\bar{c})). \tag{4.525}$$

Letting $\bar{y} \in A \times \{a\}$ be arbitrary, it follows by definition of the Cartesian product of two sets that there exist elements, say $\bar{x}$ and $\bar{a}$, with $\bar{x} \in A$, $\bar{a} \in \{a\}$ and $(\bar{x}, \bar{a}) = \bar{y}$. Here, $\bar{a} \in \{a\}$ implies $\bar{a} = a$ with (2.169), so that we obtain $\bar{y} = (\bar{x}, a)$. Moreover, $\bar{x} \in A$ implies with (4.523) the existence of the unique $y \in A \times \{a\}$ satisfying $(\bar{x}, y) \in \bar{c}$. This further implies with (4.522) that there is an element, say $\bar{\bar{x}}$, such that $(\bar{x}, y) = (\bar{\bar{x}}, (\bar{\bar{x}}, a))$. This gives $\bar{x} = \bar{\bar{x}}$ and $y = (\bar{\bar{x}}, a)$ in view of (3.3), with the consequence that

$$y = (\bar{x}, a) \quad [= \bar{y}].$$

Thus, $y = \bar{y}$ holds, so that the previously obtained $(\bar{x}, y) \in \bar{c}$ can be written as $(\bar{x}, \bar{y}) \in \bar{c}$. It now follows from this by definition of a range that $\bar{y} \in \operatorname{ran}(\bar{c})$ is true, as desired. Since $\bar{y}$ is arbitrary, we therefore conclude that (4.525) holds, so that $A \times \{a\} \subseteq \operatorname{ran}(\bar{c})$ follows to be true by definition of a subset. As $A \times \{a\}$ is a codomain of $\bar{c}$, we also have that $\operatorname{ran}(\bar{c}) \subseteq A \times \{a\}$. The conjunction of the previous two inclusions then gives $\operatorname{ran}(\bar{c}) = A \times \{a\}$ with the Axiom of Extension, so that the function $\bar{c} : A \to A \times \{a\}$ is a surjection by definition.

We now show that $\bar{c} : A \to A \times \{a\}$ is also an injection and verify accordingly

$$\forall x, x' \, ([x, x' \in A \wedge \bar{c}(x) = \bar{c}(x')] \Rightarrow x = x'). \tag{4.526}$$

We let $x, x' \in A$ be arbitrary and assume $[y =]\ \bar{c}(x) = \bar{c}(x')$. Here, we may write $y = \bar{c}(x)$ and $y = \bar{c}(x')$ also as $(x, y) \in \bar{c}$ and $(x', y) \in \bar{c}$. Here, $(x, y) \in \bar{c}$ implies with (4.522) in particular that there exists an element, say $\bar{x}$, with $(x, y) = (\bar{x}, (\bar{x}, a))$, which equation implies $x = \bar{x}$ and $y = (\bar{x}, a)$ with (3.3), and therefore $y = (x, a)$. Similarly, $(x', y) \in \bar{c}$ implies in particular that there exists an element, say $\bar{x}'$, with $(x', y) = (\bar{x}', (\bar{x}', a))$, which equation yields $x' = \bar{x}'$ and

$$[(x, a) =] \quad y = (\bar{x}', a) = (x', a).$$

We therefore obtain $(x, a) = (x', a)$, which then implies in particular the desired $x = x'$, applying once again (3.3). This proves the implication in (4.526), and since x and x' are arbitrary, we therefore conclude that (4.526) is true. Thus, the surjection $\bar{c} : A \twoheadrightarrow A \times \{a\}$ is also an injection, so that $\bar{c}$ is a bijection from A to $A \times \{a\}$, that is,

$$\bar{c} : A \rightleftarrows A \times \{a\}.$$

Now, since A is by assumption a finite set, there exist a natural number, say $\bar{n}$, and a denumeration from $\{1, \ldots, \bar{n}\}$ to A, say

$$\bar{d} : \{1, \ldots, \bar{n}\} \rightleftarrows A.$$

This shows that there exist a set n and a set d satisfying $n \in \mathbb{N}$, $d : \{1, \ldots, n\} \rightleftarrows A$ and $\bar{n} = n$, which existential sentence implies $\bar{n} = |A|$ with the definition of a cardinality, since A is finite by assumption. Now, the composition of $\bar{c}$ and $\bar{d}$ is the bijection

$$\bar{c} \circ \bar{d} : \{1, \ldots, \bar{n}\} \rightleftarrows A \times \{a\}$$

according to (3.672). This shows that there exist a set n and a set e such that $n \in \mathbb{N}$ and $e : \{1, \ldots, n\} \rightleftarrows A \times \{a\}$ hold. This existential sentence then implies that $A \times \{a\}$ is a finite set, by definition. Clearly, such an n satisfies also $\bar{n} = n$, so that

$$[|A| =] \quad \bar{n} = |A \times \{a\}|$$

follows by definition of a cardinality. These equations yield $|A \times \{a\}| = |A|$, so that the proof of the implication in (4.521) is complete. Since A and a were arbitrary, we finally conclude that the proposition is true. □

Proposition 4.110. *The cardinality of a finite set A is 0 iff the set A is empty, that is,*

$$\forall A\,(A \text{ is finite } \Rightarrow [|A| = 0 \Leftrightarrow A = \emptyset]). \tag{4.527}$$

Proof. We let A be an arbitrary finite set, so that there then exists a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to A, say $\bar{c}$; thus, we have $\bar{n} = |A|$ by definition of a cardinality.

We now prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $|A| = 0$ holds, so that substitution yields $\bar{n} = 0$, and therefore $\bar{c}$ is a bijection from $\{1, \ldots, 0\}$ to A, i.e. from $\emptyset$ to A in view of (4.239). As $\emptyset$ is the only function from $\emptyset$ to A according to Proposition 3.151, we have $\bar{c} = \emptyset$. Since the bijection $\bar{c}$ is a surjection, the range of $\bar{c}$ is identical with the codomain A, i.e. $\mathrm{ran}(\bar{c}) = A$; furthermore, $\bar{c} = \emptyset$ implies $\mathrm{ran}(\bar{c}) = \emptyset$ with (3.121), so that substitution gives $A = \emptyset$, as desired.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume $A = \emptyset$. This assumption implies with Corollary 3.201 that $\emptyset$ is a bijection from $\emptyset$ to A, which bijection we may also write as $\emptyset : \{1, \ldots, 0\} \rightleftarrows A$, using again (4.239). The existence of this bijection then implies $0 = |A|$ by definition of a cardinality, which finding completes the proof of the equivalence in (4.527).

Since A was arbitrary, we may therefore conclude that the proposed universal sentence holds. □

Proposition 4.111. *The following sentences are true.*

a) The singleton formed by any y is a finite set with cardinality 1, i.e.

$$\forall y\,(\{y\} \text{ is finite } \wedge |\{y\}| = 1). \tag{4.528}$$

b) The cardinality of a finite set is 1 iff A is the singleton formed by some y, that is,

$$\forall A\,(A \text{ is finite } \Rightarrow [|A| = 1 \Leftrightarrow \exists y\,(A = \{y\})]). \tag{4.529}$$

Proof. Concerning a), we let y be arbitrary, so that $\{(1,y)\}$ is a bijection from $\{1\}$ to $\{y\}$ (see Corollary 3.202). Thus, by definition of an initial segment of $\mathbb{N}_+$, we have $\{1\} = \{1,\ldots,1\}$, so that the existential sentence

$$\exists n, c\,(n \in \mathbb{N} \,\wedge\, c : \{1,\ldots,n\} \rightleftarrows \{y\})$$

is true. Consequently, $\{y\}$ is finite with $1 = |\{y\}|$ by definition of a cardinality. As y is arbitrary, it follows that a) is true.

Concerning b), we let A be arbitrary and assume that A is finite, so that there exists a natural number, say $\bar{n}$, and a bijection from $\{1,\ldots,\bar{n}\}$ to A, say $\bar{c}$. Here, $\bar{n} = |A|$ holds by definition of a cardinality. To prove the first part ('$\Rightarrow$') of the equivalence, we further assume $|A| = 1$, so that $\bar{n} = 1$ follows to be true. Thus, $\bar{c}$ is a bijection from $\{1,\ldots,1$ to A, i.e. from $\{1\}$ to A, and therefore in particular a surjection from $\{1\}$ to A. It then follows with (3.648) that $A = \{\bar{c}(1)\}$ holds, so that there exists an y with $A = \{y\}$, which existential sentence proves the first part of the equivalence.

To prove the second part ('$\Leftarrow$') of the equivalence in (4.529), we now assume that there exists an element, say $\bar{y}$, such that $A = \{\bar{y}\}$. It then follows with (4.528) that the singleton $A = \{\bar{y}\}$ is finite with cardinality $|A| = 1$. This completes the proof of the equivalence, and since A was arbitrary, we may therefore conclude that b) also holds. □

Lemma 4.112. *For any positive natural number n and any finite set A with cardinality n^+, it is true that the removing an element a from the set A yields a finite set with cardinality n, that is,*

$$\begin{aligned}&\forall n, A, a\,([n \in \mathbb{N}_+ \,\wedge\, A \text{ is finite} \,\wedge\, |A| = n^+ \,\wedge\, a \in A] \\ &\quad \Rightarrow [A \setminus \{a\} \text{ is finite } \wedge\, |A \setminus \{a\}| = n]).\end{aligned} \tag{4.530}$$

Proof. We let n, A and a be arbitrary, assume n to be a positive natural number, A to be a finite set with cardinality $|A| = n^+$, and a to be an element of A. By definition of a cardinality, there then exists a bijection from $\{1,\ldots,n^+\}$ to A, say $\bar{c}$. Let us now observe that the disjunction $\bar{c}(n^+) = a \vee \bar{c}(n^+) \neq a$ is true according to the Law of the Excluded Middle, so that we may prove the desired consequent in (4.530) by cases.

In the first case that $\bar{c}(n^+) = a$ is true, which we may also write as $(n^+, a) \in \bar{c}$, we have with Proposition 3.205 that $\bar{c} \setminus \{(n^+, a)\}$ is a bijection from $\{1,\ldots,n^+\} \setminus \{n^+\}$ to $A \setminus \{a\}$. Consequently, $\bar{c} \setminus \{(n^+, a)\}$ is a bijection from $\{1,\ldots,n\}$ to $A \setminus \{a\}$ in view of (4.256). Since $n \in \mathbb{N}_+$ evidently implies that n is a natural number, this bijection shows that $A \setminus \{a\}$ is a finite set with cardinality $n = |A \setminus \{a\}|$.

In the second case that $\bar{c}(n^+) \neq a$ is true, we see that $\bar{a} = \bar{c}(n^+)$ is an element of the codomain A of $\bar{c}$, where $\bar{a} \neq a$ holds. As the bijection $\bar{c}$

is in particular a surjection, we have that A is the range of $\bar{c}$. Then, the initial assumption $a \in A$ implies by definition of a range that there exists an element, say $\bar{m}$, with $(\bar{m}, a) \in \bar{c}$. We may write this also as $\bar{c}(\bar{m}) = a$, where $\bar{m} \in \{1, \ldots, n^+\}$ [$= \mathrm{dom}(\bar{c})$] holds by definition of a domain. Since $\bar{a} \neq a$ implies $\bar{c}(n^+) \neq \bar{c}(\bar{m})$ via substitution, we obtain with Proposition 3.149 the inequality $n^+ \neq \bar{m}$. We now define a function f with domain $\{1, \ldots, n^+\}$ by replacement, where the formula $\varphi(x, y)$ is given by

$$\begin{aligned} &[x = n^+ \Rightarrow y = a] \\ \wedge\, &[x = \bar{m} \Rightarrow y = \bar{a}] \\ \wedge\, &[x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\} \Rightarrow y = \bar{c}(x)]. \end{aligned} \tag{4.531}$$

To do this, we prove

$$\forall x\, (x \in \{1, \ldots, n^+\} \Rightarrow \exists! y\, (\varphi(x, y))), \tag{4.532}$$

letting x be arbitrary and assuming $x \in \{1, \ldots, n^+\}$ to be true. Let us now establish the truth of the disjunction

$$x = n^+ \vee x = \bar{m} \vee x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}. \tag{4.533}$$

To begin with, since $n^+ \in \{1, \ldots, n^+\}$ is true because of (4.247) and as $\bar{m} \in \{1, \ldots, n^+\}$ also holds (as shown before), we obtain $\{n^+\} \subseteq \{1, \ldots, n^+\}$ and $\{\bar{m}\} \subseteq \{1, \ldots, n^+\}$ with (2.184), which inclusions further implies $\{n^+\} \cup \{\bar{m}\} \subseteq \{1, \ldots, n^+\}$ with (2.252), where $\{n^+\} \cup \{\bar{m}\} = \{n^+, \bar{m}\}$ holds with (2.226), so that substitution yields $\{n^+, \bar{m}\} \subseteq \{1, \ldots, n^+\}$. It then follows with (2.263) that

$$\begin{aligned} \{1, \ldots, n^+\} &= [\{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}] \cup \{n^+, \bar{m}\} \\ &= [\{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}] \cup \{n^+\} \cup \{\bar{m}\} \\ &= \{n^+\} \cup \{\bar{m}\} \cup \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}, \end{aligned}$$

where we applied the commutativity and the associativity of the union of two sets to obtain the last equation. Therefore, the assumed $x \in \{1, \ldots, n^+\}$ implies with the definition of the union of two sets the multiple disjunction

$$x \in \{n^+\} \vee x \in \{\bar{m}\} \vee x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\},$$

which in turn gives (4.533) in view of (2.169). We now use this true disjunction to prove the desired uniquely existential sentence in (4.532) by cases.

If the first part $x = n^+$ of the disjunction (4.533) is true, then the antecedent of the first implication

$$x = n^+ \Rightarrow y = a \tag{4.534}$$

is true, so that the implication itself is true iff the consequent $y = a$ is true. Indeed, there exists a unique y such that $y = a$ holds (see Proposition 1.21), which is the constant $y = a$. Now, the previously established inequality $n^+ \neq \bar{m}$ implies $x \neq \bar{m}$, so that $x = \bar{m}$ is false. Then, the implication

$$x = \bar{m} \Rightarrow y = \bar{a} \tag{4.535}$$

is true for $y = a$, because the antecedent is false. Furthermore, $x = n^+$ implies $x \in \{n^+, \bar{m}\}$ by definition of a pair; consequently, $x \notin \{n^+, \bar{m}\}$ is false, which implies that the conjunction $x \in \{1, \ldots, n^+\} \wedge x \notin \{n^+, \bar{m}\}$ is also false, which means by definition of a set difference that $x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}$ is false. With this, we see that the third implication

$$x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\} \Rightarrow y = \bar{c}(x) \tag{4.536}$$

is true for $y = a$, as the antecedent is false. We thus showed that there exists a unique y such that $\varphi(x, y)$ holds, if $x = n^+$ is true.

Similarly, if the second part $x = \bar{m}$ of the disjunction (4.533) is true, then the antecedent of the second implication (4.535) is true, so that the implication itself is true iff the consequent $y = \bar{a}$ is true. Because of Proposition 1.21 there indeed exists a unique y satisfying $y = \bar{a}$, which is the constant $y = \bar{a}$. Now, $n^+ \neq \bar{m}$ implies $x \neq n^+$, so that $x = n^+$ is false. Then, the first implication (4.534) with $y = \bar{a}$ has a false antecedent and is therefore true. Moreover, $x = \bar{m}$ evidently implies $x \in \{n^+, \bar{m}\}$ as before, so that $x \in \{1, \ldots, n^+\} \setminus \{\bar{n}, \bar{m}\}$ turns out to be false and the third implication (4.536) to be true. Thus, there also exists a unique y such that $\varphi(x, y)$ is true if $x = \bar{m}$ holds.

Finally, if the third part $x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}$ of the disjunction (4.533) is true, then the antecedent of the third implication (4.536) is true, so that the implication itself is true iff $y = \bar{c}(x)$ holds. This equation is evidently satisfied by the unique constant $y = \bar{c}(x)$. The assumption $x \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}$ also implies that $x \notin \{n^+, \bar{m}\}$, which means by definition of a pair in connection with De Morgan's Law for sentences (1.51) that $x \neq n^+$ and $x \neq \bar{m}$ are both true. Then, as the equations $x = n^+$ and $x = \bar{m}$ are false, the implications (4.534) and (4.535) have false antecedents and are therefore true for $y = \bar{c}(x)$. Thus, there exists also in this case a unique y such that $\varphi(x, y)$ holds.

This proves the implication in (4.532), and since x was arbitrary, we may therefore conclude that the universal (4.532) is true. It then follows with Theorem 3.160 that there exists a unique function f with domain $\{1,\ldots,n^+\}$ such that $\varphi(x,f(x))$ holds for any $x\in\{1,\ldots,n^+\}$, and we may write this mapping as

$$x\mapsto f(x)=\begin{cases} a & \text{if } x=n^+\\ \bar{a} & \text{if } x=\bar{m}\\ \bar{c}(x) & \text{if } x\in\{1,\ldots,n^+\}\setminus\{n^+,\bar{m}\}\end{cases}$$

We now verify that f is an injection, i.e. that f satisfies (3.615) with $X=\{1,\ldots,n^+\}$. Let us first rewrite that sentence equivalently as

$$\forall x,x'\,(x,x'\in\{1,\ldots,n^+\}\Rightarrow[f(x)=f(x')\Rightarrow x=x']) \tag{4.537}$$

by applying (1.49). We let x and x' be arbitrary in $\{1,\ldots,n^+\}$ and prove the implication

$$f(x)=f(x')\Rightarrow x=x'. \tag{4.538}$$

Let us recall that $x\in\{1,\ldots,n^+\}$ implies the truth of the disjunction (4.533).

If $x=n^+$ holds, then the definition of f gives $f(x)=a$. Observing now that $x'\in\{1,\ldots,n^+\}$ also holds, we evidently obtain the true disjunction (4.533), which we established for an arbitrary element of $\{1,\ldots,n^+\}$. Then, in case of $x'=n^+$ $(=x)$, we obtain $f(x')=a$ $(=f(x))$ by definition of f, so that $f(x)=f(x')$ and $x=x'$ are both true; consequently, the implication (4.538) takes the value 'true'. In case of $x'=\bar{m}$, we obtain $f(x')=\bar{a}$ $(\neq a)$, so that $f(x')\neq f(x)$ is true, so that the implication (4.538) has a false antecedent and is thus true. Finally, in case of $x'\in\{1,\ldots,n^+\}\setminus\{n^+,\bar{m}\}$, we obtain $f(x')=\bar{c}(x')$ (by definition of f) as well as $x'\notin\{n^+,\bar{m}\}$ and therefore $x'\neq\bar{m}$ (by definition of a pair). Recalling that $\bar{c}(\bar{m})=a$ $(=f(x))$ holds and noting that $x'\neq\bar{m}$ implies $\bar{c}(x')\neq\bar{c}(\bar{m})$ with the Injection Criterion and the injectivity of $\bar{c}$, we see that $f(x')\neq f(x)$ is again true; thus, the implication (4.538) holds also in this case.

If $x=\bar{m}$ holds, then $f(x)=\bar{a}$. Now, in case of $x'=n^+$, we have $f(x')=a$ $(\neq\bar{a})$ and therefore $f(x')\neq f(x)$, so that the implication (4.538) is true. In case of $x'=\bar{m}$ $(=x)$, we have $f(x')=\bar{a}$ $(=f(x))$; consequently, $f(x')=f(x)$ and $x'=x$ are both true, so that (4.538) holds again. Finally, in case of $x'\in\{1,\ldots,n^+\}\setminus\{n^+,\bar{m}\}$, we have $f(x')=\bar{c}(x')$ as well as $x'\notin\{n^+,\bar{m}\}$, and therefore $x'\neq n^+$ (by definition of a pair). Recalling that $\bar{c}(n^+)=\bar{a}$ $(=f(x))$ holds and observing that $x'\neq n^+$ implies $\bar{c}(x')\neq\bar{c}(\bar{n})$ with the Injection Criterion, we have that $f(x')\neq f(x)$ is true once again, with the consequence that (4.538) is true also in the present case.

If $x\in\{1,\ldots,n^+\}\setminus\{n^+,\bar{m}\}$ holds, then $f(x)=\bar{c}(x)$ and also $x\notin\{n^+,\bar{m}\}$, so that $x\neq n^+$ and $x\neq\bar{m}$ are both true. In case of $x'=n^+$, which gives $f(x') = a$ $(= \bar{c}(\bar{m}))$, we observe that $x \neq \bar{m}$ implies $\bar{c}(x) \neq \bar{c}(\bar{m})$ with the Injection Criterion, so that $f(x) \neq f(x')$ and consequently (4.538) holds. In case of $x' = \bar{m}$, which gives $f(x') = \bar{a}$ $(= \bar{c}(n^+))$, we notice that $x \neq n^+$ now implies $\bar{c}(x) \neq \bar{c}(n^+)$ with the injectivity of $\bar{c}$; thus, $f(x) \neq f(x')$ is true, and therefore also (4.538). Finally, in case of $x' \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}$, we obtain $f(x') = \bar{c}(x')$. Now, the disjunction $\bar{c}(x) = \bar{c}(x') \vee \bar{c}(x) \neq \bar{c}(x')$ is true because of the Law of the Excluded Middle. On the one hand, if $\bar{c}(x) = \bar{c}(x')$ is true, then substitution yields the true equation $f(x) = f(x')$, and it follows with the injectivity of $\bar{c}$ that $x = x'$ holds. Thus, the implication (4.538) takes the value 'true'. On the other hand, if $\bar{c}(x) \neq \bar{c}(x')$ is true, then this gives $f(x) \neq f(x')$ by substitution, and the implication (4.538) turns out to be true, being based on a false antecedent.

We thus completed the proof of (4.538) by cases; as x and x' were arbitrary, we may therefore conclude that the universal sentence (4.537) holds, so that f is indeed an injection.

Next, we verify that the range of f is identical with A. For this purpose, we apply the Equality Criterion for sets and prove accordingly

$$\forall y\,(y \in \operatorname{ran}(f) \Leftrightarrow y \in A). \tag{4.539}$$

We let y be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in \operatorname{ran}(f)$ to be true. Then, by definition of a range, there exists an element, say $\bar{x}$, such that $(\bar{x}, y) \in f$. Consequently, $\bar{x}$ is by definition of a domain an element of $\operatorname{dom}(f) = \{1, \ldots, n^+\}$. This evidently implies the disjunction (4.533), in which we replace the arbitrary x by $\bar{x}$.

Now, if $\bar{x} = n^+$ holds, then the definition of f gives $f(\bar{x}) = a$. Since $(\bar{x}, y) \in f$ may be written in function notation as $f(\bar{x}) = y$, we obtain after substitution $y = a$. The initial assumption $a \in A$ thus gives the desired $y \in A$.

If $\bar{x} = \bar{m}$ holds, then we obtain $f(\bar{x}) = \bar{a}$ by definition of f, so that $y = \bar{a}$. Then, the previously established $\bar{a} \in A$ also gives $y \in A$.

Finally, if $\bar{x} \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}$ holds, then $f(\bar{x}) = \bar{c}(\bar{x})$ is true by definition of f. Since $\bar{c}$ is a bijection from $\{1, \ldots, n^+\}$ to A, we evidently have $\bar{c}(\bar{x}) \in A$, and therefore $f(\bar{x}) \in A$ due to the preceding equation. Recalling $f(\bar{x}) = y$, we thus see that $y \in A$ holds also in this case, completing the proof of the first part of the equivalence in (4.539).

To prove the second part ('$\Leftarrow$'), we now assume that $y \in A$ is true. Recalling that A is the range of the bijection/surjection $\bar{c}$, we see that there exists an element, say $\bar{x}$, such that $(\bar{x}, y) \in \bar{c}$ holds. Consequently, $\bar{x}$ is an element of the domain $\{1, \ldots, n^+\}$ of $\bar{c}$. Let us also recall that $\bar{c}(n^+) = \bar{a}$ and $\bar{c}(\bar{m}) = a$ hold, and that $(\bar{x}, y) \in \bar{c}$ means $\bar{c}(\bar{x}) = y$.

Now, if $\bar{x} = n^+$ holds, then substitution yields $\bar{c}(n^+) = y$ and then $\bar{a} = y$. By definition of f, we have $f(\bar{m}) = \bar{a}$, which implies $f(\bar{m}) = y$. This means $(\bar{m}, y) \in f$, so that y is an element of the range of f.

If $\bar{x} = \bar{m}$ holds, then we obtain $\bar{c}(\bar{m}) = y$ and then $a = y$. Here, $f(n^+) = a$ holds by definition of f, which implies $f(n^+) = y$. Clearly, y is then an element of $\mathrm{ran}(f)$.

Finally, if $\bar{x} \in \{1, \ldots, n^+\} \setminus \{n^+, \bar{m}\}$ holds, then the definition of f gives $f(\bar{x}) = \bar{c}(\bar{x})$ $(= y)$, so that $f(\bar{x}) = y$ is true. We therefore have $y \in \mathrm{ran}(f)$ also in this case.

Thus, the proof of the second part of the equivalence in (4.539) is complete. As y was arbitrary, we may then further conclude that the universal sentence (4.539) is true, which implies $\mathrm{ran}(f) = A$ with the Equality Criterion for sets. Then, by definition of a surjection, we have $f : \{1, \ldots, n^+\} \twoheadrightarrow A$. Since f is also an injection with domain $\{1, \ldots, n^+\}$, for which we may use any codomain (see Note 3.23), we see that f is a bijection from $\{1, \ldots, n^+\}$ to A. By definition of f, it is true that $f(n^+) = a$. We may therefore proceed in analogy to the already established case of $\bar{c}(n^+) = a$. Thus, observing that $f(n^+) = a$ may be written also as $(n^+, a) \in f$, it follows with Proposition 3.205 that $f \setminus \{(n^+, a)\}$ is a bijection from $\{1, \ldots, n^+\} \setminus \{n^+\}$ to $A \setminus \{a\}$, and therefore a bijection from $\{1, \ldots, n\}$ to $A \setminus \{a\}$ in view of (4.256). This bijection clearly shows that the set $A \setminus \{a\}$ is finite, having again the cardinality $|A \setminus \{a\}| = n$, completing the proof by cases of the consequent in (4.530). As n, A and a were initially arbitrary, we may now finally conclude that the proposed universal sentence (4.530) is true. □

Lemma 4.113. *The union of a finite set A and a finite set B with cardinality n is itself finite, that is,*

$$\forall n, A, B\,([n \in \mathbb{N}_+ \,\wedge\, A \text{ is finite} \,\wedge\, B \text{ is finite} \,\wedge\, |B| = n] \Rightarrow A \cup B \text{ is finite}). \tag{4.540}$$

Proof. Let us first rewrite (4.540) equivalently as (using (1.90))

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \forall A, B\,([A \text{ is finite} \wedge B \text{ is finite} \wedge |B| = n] \Rightarrow A \cup B \text{ is finite})). \tag{4.541}$$

We now carry out a proof by mathematical induction. To prove the base case ($n = 1$), we let A and B be arbitrary such that A and B are finite and such that $|B| = 1$ holds. The latter implies with (4.529) that there exists an element, say $\bar{y}$, such that $B = \{\bar{y}\}$ is true. Then, the finiteness of A implies the finiteness of $A \cup \{\bar{y}\}$ with (4.467), so that $A \cup B$ follows to be finite via substitution based on the preceding equation. This finding proves the base case.

Regarding the induction step, we let n be arbitrary in $\mathbb{N}_+$, make the induction assumption

$$\forall A, B\,([A \text{ is finite } \wedge\ B \text{ is finite } \wedge\ |B| = n] \Rightarrow A \cup B \text{ is finite}), \tag{4.542}$$

and demonstrate that this implies

$$\forall A, B\,([A \text{ is finite } \wedge\ B \text{ is finite } \wedge\ |B| = n^+] \Rightarrow A \cup B \text{ is finite}). \tag{4.543}$$

For this purpose, we let A and B be arbitrary such that A and B are finite with $|B| = n^+$. Since $n \in \mathbb{N}_+$ evidently implies $n \in \mathbb{N}$ and therefore $n^+ \neq 0$ with (4.35), we may apply substitution based on the equation $|B| = n^+$ to infer from the preceding inequality the truth of $|B| \neq 0$. This inequality yields $B \neq \emptyset$ with (4.527), so that there exists in view of (2.42) an element in B, say $\bar{y}$. Thus, the conjunction

$$n \in \mathbb{N}_+\ \wedge\ B \text{ is finite } \wedge\ |B| = n^+\ \wedge\ \bar{y} \in B$$

is true, which implies with (4.530) that $B \setminus \{\bar{y}\}$ is a finite set with cardinality $|B \setminus \{\bar{y}\}| = n$. This finding, together with the assumption that A is finite, implies with the induction assumption (4.542) that $A \cup (B \setminus \{\bar{y}\})$ is a finite set. Then, the union

$$[A \cup (B \setminus \{\bar{y}\})] \cup \{\bar{y}\}$$

is also finite due to (4.467), and the preceding union is identical with

$$A \cup [(B \setminus \{\bar{y}\}) \cup \{\bar{y}\}] \tag{4.544}$$

because of the Associative Law for the union of two sets, so that the latter set is also finite. Then, the fact $\bar{y} \in B$ implies $\{\bar{y}\} \subseteq B$ with (2.184), which in turn implies

$$(B \setminus \{\bar{y}\}) \cup \{\bar{y}\} = B$$

with (2.263). Consequently, the finite set in (4.544) is identical with $A \cup B$, which proves the finiteness of the latter. Since A and B are arbitrary, we may therefore conclude that the universal sentence (4.543) is true. As n was also arbitrary, we may now further conclude that the induction step holds (besides the base case), so that the proof of (4.541) by mathematical induction is complete. Consequently, the proposed equivalent sentence (4.540) is also true. □

Theorem 4.114 (Finiteness of the union of two finite sets). *The union of two finite sets is finite, that is,*

$$\forall A, B\,([A \text{ is finite } \wedge\ B \text{ is finite}] \Rightarrow A \cup B \text{ is finite}). \tag{4.545}$$

Proof. We let A and B be sets and assume that A and B are finite. By definition of a finite set, there then exist a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to B, say $\bar{c}$. Furthermore, the definition of a cardinality gives $\bar{n} = |B|$. Noting that $\bar{n} \in \mathbb{N}$ implies the true disjunction $\bar{n} = 0 \lor \bar{n} \in \mathbb{N}_+$ with (2.310), we may apply now a proof by cases.

If $\bar{n} = 0$ holds, then we obtain $|B| = 0$ via substitution and therefore $B = \emptyset$ with (4.527), which gives $A \cup B = A \cup \emptyset = A$ with (2.216). Since A is by assumption finite, we thus see that $A \cup B$ is finite.

If $\bar{n} \in \mathbb{N}_+$ holds, then the conjunction

$$\bar{n} \in \mathbb{N}_+ \land A \text{ is finite} \land B \text{ is finite} \land |B| = \bar{n}$$

is true, which then implies with (4.540) that $A \cup B$ is finite.

Thus, $A \cup B$ is finite in any case, and since A and B were arbitrary, we may therefore conclude that (4.545) is true. □

Proposition 4.115. *For any natural number n, any finite set A with cardinality n and any proper subset S of A, it is true that S is a finite set with cardinality less than n, that is,*

$$\forall n, A, S\,([n \in \mathbb{N} \land A \text{ is finite} \land |A| = n \land S \subset A] \Rightarrow [S \text{ is finite} \land |S| < n]). \tag{4.546}$$

Proof. Let us first rewrite (4.546) equivalently as

$$\forall n\,(n \in \mathbb{N} \Rightarrow \forall A, S\,([A \text{ is finite} \land |A| = n \land S \subset A] \Rightarrow [S \text{ is finite} \land |S| < n])) \tag{4.547}$$

by means of (1.90). We now prove the universal sentence with respect to n by mathematical induction. Regarding the base case ($n = 0$), we prove

$$\forall A, S\,([A \text{ is finite} \land |A| = 0 \land S \subset A] \Rightarrow [S \text{ is finite} \land |S| < 0]), \tag{4.548}$$

letting A and S be arbitrary. Let us now prove by contradiction that the antecedent of the implication in (4.548) is false, i.e. that the negation of the antecedent is true. For this purpose, we assume

$$\neg\neg[A \text{ is finite} \land |A| = 0 \land S \subset A]$$

to be true, so that we obtain with the Double Negation Law in particular the true sentences $|A| = 0$ and $S \subset A$. The preceding equation yields $A = \emptyset$ by definition of a cardinality, so that $S \subset A$ is false due to (2.47), which finding is in contradiction to $S \subset A$. Thus, the implication in (4.548) has a false antecedent and is therefore true. Since A and S were arbitrary, we may infer from this the truth of the base case.

Regarding induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption

$$\forall A, S\,([A \text{ is finite} \wedge |A| = n \wedge S \subset A] \Rightarrow [S \text{ is finite} \wedge |S| < n]), \quad (4.549)$$

and show that this implies

$$\forall A, S\,([A \text{ is finite} \wedge |A| = n^+ \wedge S \subset A] \Rightarrow [S \text{ is finite} \wedge |S| < n^+]). \quad (4.550)$$

To prove the latter sentence, we let A and S be arbitrary and prove the implication directly, assuming that A is a finite set with cardinality $|A| = n^+$ and that S is a proper subset of A. Thus, there exists (by definition of a cardinality) a particular bijection

$$\bar{c} : \{1, \ldots, n^+\} \rightleftarrows A. \quad (4.551)$$

Let us observe that $n \in \mathbb{N}$ implies $n^+ \in \mathbb{N}_+$ with (4.42) and therefore $n^+ \in \{1, \ldots, n^+\}$ with (4.247). Since $\{1, \ldots, n^+\}$ is the domain of $\bar{c}$, there is an element in the codomain/range A, say $\bar{y}$, such that $(n^+, \bar{y}) \in \bar{c}$ holds. Then, we may apply Proposition 3.205 to obtain from (4.551) the bijection

$$\bar{c} \setminus \{(n^+, \bar{y})\} : \{1, \ldots, n^+\} \setminus \{n^+\} \rightleftarrows A \setminus \{\bar{y}\}. \quad (4.552)$$

We now prove by cases that S is a finite set with cardinality $|S| = n^+$, based on the disjunction $n = 0 \vee n \in \mathbb{N}_+$ implied by $n \in \mathbb{N}$ with (2.310).

If $n = 0$ holds, then $n^+ = 1$ is true according to (2.291), then we have the bijection $\bar{c} : \{1, \ldots, 1\} \rightleftarrows A$, which we may write as $\bar{c} : \{1\} \rightleftarrows A$ by applying the definition of an initial segment. This shows with Exercise 3.81 that A is the singleton $\{\bar{c}(1)\}$. Then, $A = \{\bar{c}(1)\}$ implies together with the assumption $S \subset A$ that $S \subset \{\bar{c}(1)\}$. This further implies $S = \emptyset$ with (2.187), so that S is a finite set by definition, and we obtain $|S| = 0$ with (4.527). Since $n \in \mathbb{N}$ implies the inequalities $0 \leq n < n^+$ with (4.187) and (4.153), so that $0 < n^+$ follows to be true with the Transitivity Formula for $\leq$ and $<$, we obtain the desired $|S| < n^+$ after substitution.

If $n \in \mathbb{N}_+$ holds, then this gives the equation $\{1, \ldots, n\} = \{1, \ldots, n^+\} \setminus \{n^+\}$ with (4.256), so that we may write (4.552) as

$$\bar{c} \setminus \{(n^+, \bar{y})\} : \{1, \ldots, n\} \rightleftarrows A \setminus \{\bar{y}\}.$$

This shows that $A \setminus \{\bar{y}\}$ is a finite set with cardinality $|A \setminus \{\bar{y}\}| = n$, so that the assumed $|A| = n^+$ yields via substitution

$$|A| = n^+ = |A \setminus \{\bar{y}\}|^+.$$

We now consider the two subcases bases on the disjunction $\bar{y} \notin S \vee \bar{y} \in S$, which evidently holds according to the Law of the Excluded Middle.

Regarding the first subcase $\bar{y} \notin S$, we note that $S \subset A$ implies in particular $S \subseteq A$ by definition of a proper subset. Then, the conjunction of this and the case assumption $\bar{y} \notin S$ implies $S \subseteq A \setminus \{\bar{y}\}$ with Proposition 2.63, so that the disjunction of $S \subset A \setminus \{\bar{y}\}$ and $S = A \setminus \{\bar{y}\}$ is true due to (2.26). We may use this true disjunction to prove by cases that S is a finite set with cardinality $|S| < n$. On the one hand, if $S \subset A \setminus \{\bar{y}\}$ holds, this implies – together with the previously established fact that $A \setminus \{\bar{y}\}$ is finite with $|A \setminus \{\bar{y}\}| = n$ – due to the induction assumption (4.549) that S is a finite set with cardinality $|S| < n$. On the other hand, if $S = A \setminus \{\bar{y}\}$ holds, then the previously mentioned fact that $A \setminus \{\bar{y}\}$ is finite with $|A \setminus \{\bar{y}\}| = n$ implies via substitution that S is finite with $|S| = n$, completing the current proof by cases. Recalling that $n \in \mathbb{N}$ implies $n < n^+$ due to (4.153), we then obtain the desired inequality $|S| < n^+$ with the transitivity of the linear ordering $<$ of $\mathbb{N}$.

The second subcase $\bar{y} \in S$ implies together with the assumption $S \subset A$

$$S \setminus \{\bar{y}\} \subset A \setminus \{\bar{y}\},$$

according to Proposition 2.64. Together with the fact that $A \setminus \{\bar{y}\}$ is finite with $|A \setminus \{\bar{y}\}| = n$, this implies with the induction assumption (4.549) that $S \setminus \{\bar{y}\}$ is a finite set with $|S \setminus \{\bar{y}\}| < n$. Consequently, there exists by definition of a finite set a natural number, say $\bar{m}$, and a bijection from $\{1, \ldots, \bar{m}\}$ to $S \setminus \{\bar{y}\}$, say $\bar{d}$, so that $|S \setminus \{\bar{y}\}| = \bar{m}$. holds by definition of a cardinality. It then follows from $|S \setminus \{\bar{y}\}| < n$ that $\bar{m} < n$ holds, which further implies $\bar{m}^+ \leq n$ $(< n^+)$ with (4.157) and therefore $m^+ < n^+$ with the Transitivity Formula for $\leq$ and $<$. Since $S \setminus \{\bar{y}\}$ is a finite set with $|S \setminus \{\bar{y}\}| = \bar{m}$ and as $\bar{y} \notin S \setminus \{\bar{y}\}$ also holds according to (2.179), it furthermore follows with (4.507) that $(S \setminus \{\bar{y}\}) \cup \{\bar{y}\}$ is a finite set with cardinality $\bar{m}^+$. Because the assumed $\bar{y} \in S$ gives $\{\bar{y}\} \subseteq S$ with (2.184), we see in light of (2.263) that $(S \setminus \{\bar{y}\}) \cup \{\bar{y}\}$ is identical with the set S, so that S is finite with $|S| = \bar{m}^+$, which successor we already showed to be less than n^+. Thus, S is finite and $|S| < n^+$ is also true, completing the two nested proofs by cases.

Since A and S were arbitrary, we may therefore conclude that the universal sentence (4.550) is true. As n was also arbitrary, we may then further conclude that the induction step holds, so that the proof by mathematical induction of (4.547) is complete; thus, the sentence (4.546) is also true. □

Corollary 4.116. *Any proper subset S of a finite set A is itself a finite set with cardinality less than the cardinality of A, that is,*

$$\forall A, S\,([A \text{ is finite} \wedge S \subset A] \Rightarrow [S \text{ is finite} \wedge |S| < |A|]). \tag{4.553}$$

Proof. We let A and S be arbitrary sets, assume that A is finite, and assume moreover that S is a proper subset of A. Since A is finite, there exist a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}$ to A, say $\bar{c}$. The existence of this bijection shows in light of the definition of a cardinality that $\bar{n} = |A|$ holds. Thus, the multiple conjunction

$$\bar{n} \in \mathbb{N} \,\wedge\, A \text{ is finite} \,\wedge\, |A| = \bar{n} \,\wedge\, S \subset A$$

is true, which then implies with (4.546) that S is finite and that $|S| < \bar{n}$ holds. Applying now substitution to this inequality based on the previously established equation $\bar{n} = |A|$ yiels $|S| < |A|$. These findings prove the implication in (4.553), and since A and S were arbitrary, we may therefore conclude that the corollary is true. □

Proposition 4.117. *For any positive natural number n and any finite subset A of $\mathbb{N}$ with cardinality n it is true that A is bounded from above, that is,*

$$\begin{aligned}&\forall n, A\,([n \in \mathbb{N}_+ \,\wedge\, A \text{ is finite} \,\wedge\, A \subseteq \mathbb{N} \,\wedge\, |A| = n] \\ &\quad \Rightarrow A \text{ is bounded from above}).\end{aligned} \tag{4.554}$$

Proof. We first apply (1.90) to rewrite (4.554) equivalently as

$$\begin{aligned}&\forall n\,(n \in \mathbb{N}_+ \Rightarrow \forall A\,([A \text{ is finite} \,\wedge\, A \subseteq \mathbb{N} \,\wedge\, |A| = n] \\ &\quad \Rightarrow A \text{ is bounded from above})),\end{aligned} \tag{4.555}$$

and we then prove this universal sentence via mathematical induction. Regarding the case $(n = 1)$, we let A be an arbitrary set and assume A to be a finite subset of $\mathbb{N}$ with cardinality $|A| = 1$. These assumptions imply with (4.529) that there exists a constant, say $\bar{y}$, such that $A = \{\bar{y}\}$ holds. Consequently, $\bar{y}$ is an upper bound for the singleton $A = \{\bar{y}\}$ according to Proposition 3.91 – applied to the totally ordered set $(\mathbb{N}, \leq)$. Thus, an upper bound for A exists, so that the set A is bounded from above. Since A is arbitrary, we may therefore conclude that the base case holds.

Regarding the induction step, we let $n \in \mathbb{N}_+$ be arbitrary, make the induction assumption

$$\forall A\,([A \text{ is finite} \wedge A \subseteq \mathbb{N} \wedge |A| = n] \Rightarrow A \text{ is bounded from above}), \tag{4.556}$$

and show that this implies

$$\forall A\,([A \text{ is finite} \,\wedge\, A \subseteq \mathbb{N} \,\wedge\, |A| = n^+] \Rightarrow A \text{ is bounded from above}). \tag{4.557}$$

To prove this universal sentence, we take an arbitrary set A and assume A to be a finite subset of $\mathbb{N}$ with cardinality $|A| = n^+$. Evidently, $n^+ \neq 0$ holds with (4.35), so that $|A| \neq 0$ is true, which then further implies $A \neq \emptyset$ with (4.527). Since A is nonempty, there clearly exists an element in A, say $\bar{y}$. Thus, the conjunction

$$n \in \mathbb{N}_+ \wedge A \text{ is finite } \wedge |A| = n^+ \wedge \bar{y} \in A$$

holds, which implies with (4.530) that $A \setminus \{\bar{y}\}$ is a finite set with $|A \setminus \{\bar{y}\}| = n$. Let us also observe that $A \setminus \{\bar{y}\} \subseteq A$ holds due to (2.125), which then implies together with the assumption $A \subseteq \mathbb{N}$ and the transitivity of $\subseteq$ that $A \setminus \{\bar{y}\} \subseteq \mathbb{N}$. These findings then imply with the induction assumption (4.556) that $A \setminus \{\bar{y}\}$ is bounded from above, so that there exists an element of $\mathbb{N}$, say $\bar{u}$, such that

$$\forall y \, (y \in A \setminus \{\bar{y}\} \Rightarrow y \leq \bar{u}) \tag{4.558}$$

holds. Let us notice that the fact $\bar{y} \in A$ implies $\{\bar{y}\} \subseteq A$ with (2.184), so that we obtain

$$(A \setminus \{\bar{y}\}) \cup \{\bar{y}\} = A \tag{4.559}$$

with (2.263). We now prove by cases that A is bounded from above, based on the true disjunction $\bar{y} \leq \bar{u} \vee \bar{y} \leq \bar{u} \leq \bar{y}$ (applying the totality of the standard total ordering $\leq$ of $\mathbb{N}$).

In the first case, we assume $\bar{y} \leq \bar{u}$ and demonstrate the truth of

$$\forall y \, (y \in A \Rightarrow y \leq \bar{u}). \tag{4.560}$$

Letting y be arbitrary in A, it follows with (4.559) and the definition of the union of a pair that the disjunction $y \in A \setminus \{\bar{y}\} \vee y \in \{\bar{y}\}$ holds, which we now use to prove $y \leq \bar{u}$ by cases. On the one hand, if $y \in A \setminus \{\bar{y}\}$ is true, then it follows with (4.558) that $y \leq \bar{u}$ holds, as desired. On the other hand, if $y \in \{\bar{y}\}$ is true, then (2.169) gives $y = \bar{y}$, so that the desired $y \leq \bar{u}$ follows from the current case assumption $\bar{y} \leq \bar{u}$. We thus completed the proof of $y \leq \bar{u}$ by cases, and since y was arbitrary, we may therefore conclude that the universal sentence (4.560) holds. Thus, $\bar{u}$ is an upper bound for A in the first case.

In the second case, we assume $\bar{u} \leq \bar{y}$ and verify now

$$\forall y \, (y \in A \Rightarrow y \leq \bar{y}), \tag{4.561}$$

assuming that y is an arbitrary element of A. As in the first case, this means that $y \in A \setminus \{\bar{y}\}$ or $y \in \{\bar{y}\}$ is true. On the one hand, if $y \in A \setminus \{\bar{y}\}$ holds, then (4.558) gives $y \leq \bar{u}$. The conjunction of this and the case assumption

$\bar{u} \leq \bar{y}$ then implies $y \leq \bar{y}$ with the transitivity of the standard total ordering $\leq$ of $\mathbb{N}$, which was to be shown. If, on the other hand, $y \in \{\bar{y}\}$ holds, which yields $y = \bar{y}$ as before, then the disjunction $y < \bar{y} \vee y = \bar{y}$ is also true (irrespective of the truth value of $y < \bar{y}$), which evidently means that the desired inequality $y \leq \bar{y}$ holds again. As y is arbitrary, we may therefore conclude that (4.561) is true, which shows that $\bar{y}$ is now an upper bound for A in the second case.

As there exists an upper bound for A in any case, it follows that A is bounded from above, so that the proof of the implication in (4.557) is complete. Since A is arbitrary, we may then further conclude that (4.557) holds. As n was also arbitrary, we may infer from this the truth of the induction step, which completes the proof of (4.555) via mathematical induction and thus the proof of the proposition. □

Corollary 4.118. *Any finite subset of* $\mathbb{N}$ *is bounded from above, that is,*

$$\forall A\,([A \text{ is finite } \wedge\ A \subseteq \mathbb{N}] \Rightarrow A \text{ is bounded from above}). \tag{4.562}$$

Proof. Letting A be an arbitrary set such that A is finite and a subset of $\mathbb{N}$, we have that there exists a particular bijection from $\{1, \ldots, \bar{n}\}$ to A, where $\bar{n}$ is a particular natural number and moreover the cardinality of A. Let us now observe the truth of $\bar{n} = 0 \vee \bar{n} \in \mathbb{N}_+$ in light of (2.310) and let us now use this disjunction to prove by cases that A is bounded from above.

In case of $\bar{n} = 0$, we obtain $|A| = 0$, which implies $A = \emptyset$ with (4.527), so that any natural number (say, 1) is an upper bound for $A = \emptyset$ according to Proposition 3.90 – applied to the totally ordered set $(\mathbb{N}, \leq)$. Thus, an upper bound for A exists, so that the set A is bounded from above if its cardinality is $\bar{n} = 0$.

In the other case of $\bar{n} \in \mathbb{N}_+$, we may apply (4.554) to obtain the desired result that A is bounded from above.

Since A was initially arbitrary, we may therefore conclude that the corollary holds. □

Corollary 4.119. *For any finite, nonempty subset A of* $\mathbb{N}$ *it is true that the maximum of A exists.*

Proof. We let A be an set and assume that A is a finite and nonempty subset of $\mathbb{N}$. It then follows with the preceding Corollary 4.118 that A is bounded from above. Since A is a nonempty and bounded-from-above subset of $\mathbb{N}$, it follows with Corollary 4.41b) that the greatest element of A exists. Since A is arbitrary, we may therefore conclude that the proposed universal sentence holds. □

Lemma 4.120. *For any positive natural number n, any finite set A and any finite set B with cardinality n, it is true that the Cartesian product of A and B is finite, that is,*

$$\forall n, A, B\,([n \in \mathbb{N}_+ \,\wedge\, A \text{ is finite} \,\wedge\, B \text{ is finite} \,\wedge\, |B| = n] \Rightarrow A \times B \text{ is finite}). \tag{4.563}$$

Proof. We first apply (1.90) to write (4.563) equivalently as

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \forall A, B\,([A \text{ is finite} \wedge B \text{ is finite} \wedge |B| = n] \Rightarrow A \times B \text{ is finite})) \tag{4.564}$$

and apply then a proof by mathematical induction.

Regarding the base case ($n = 1$), we let A and B be arbitrary finite sets with $|B| = 1$, and show that this implies the finiteness of $A \times B$. Here, the finiteness of B implies together with $|B| = 1$ that there exists an element, say $\bar{y}$, with $B = \{\bar{y}\}$ (see Proposition 4.111b)), so that substitution yields $A \times B = A \times \{\bar{y}\}$. In view of Proposition 4.109, the finiteness of A implies then that the preceding Cartesian product is itself finite, which proves the base case.

Regarding the induction step, we let n be arbitrary in $\mathbb{N}_+$, make the induction assumption

$$\forall A, B\,([A \text{ is finite} \,\wedge\, B \text{ is finite} \,\wedge\, |B| = n] \Rightarrow A \times B \text{ is finite}), \tag{4.565}$$

and show that this implies

$$\forall A, B\,([A \text{ is finite} \,\wedge\, B \text{ is finite} \,\wedge\, |B| = n^+] \Rightarrow A \times B \text{ is finite}). \tag{4.566}$$

To prove this universal sentence, we let A and B be arbitrary finite sets such that $|B| = n^+$ holds. The initial assumption $n \in \mathbb{N}_+$ clearly implies $n \in \mathbb{N}$ and then $n^+ \neq 0$ with Property 1 of a counting domain – applied to $(\mathbb{N}, s^+, 0)$. Then, the assumed $|B| = n^+$ gives with the preceding inequality after substitution $|B| \neq 0$, so that $B \neq \emptyset$ holds due to (4.527) in connection with the Law of Contraposition. Consequently, there exists an element in B, say $\bar{y}$, according to Proposition 2.11. The previous findings show that the multiple conjunction

$$n \in \mathbb{N}_+ \,\wedge\, B \text{ is finite} \,\wedge\, |B| = n^+ \,\wedge\, \bar{y} \in B$$

holds, which implies with (4.530) that $B \setminus \{\bar{y}\}$ is finite and that $|B \setminus \{\bar{y}\}| = n$. Together with the assumption that A is finite, this equation implies with the induction assumption (4.565) that the Cartesian product $A \times (B \setminus \{\bar{y}\})$ is finite. Let us now observe that $\bar{y} \in B$ implies $\{\bar{y}\} \subseteq B$ with (2.184), so that (2.263) gives the equation $(B \setminus \{\bar{y}\}) \cup \{\bar{y}\} = B$. With this and (3.62), we then obtain

$$A \times B = A \times [(B \setminus \{\bar{y}\}) \cup \{\bar{y}\}] = [A \times (B \setminus \{\bar{y}\})] \cup [A \times \{\bar{y}\}]. \quad (4.567)$$

It follows with Proposition 4.109 that $A \times \{\bar{y}\}$ is a finite set. Together with the previous finding that $A \times (B \setminus \{\bar{y}\})$ is finite, this implies with Theorem 4.114 that the union (4.567), i.e. $A \times B$, is itself finite, which proves the implication in (4.566). Since A and B are arbitrary, we therefore conclude that the universal sentence (4.566) is true, and as n is also arbitrary, we then further conclude that the induction step holds. Therefore, (4.564) is true, so that the proof of the lemma is complete. □

Theorem 4.121 (Finiteness of the Cartesian product of two finite sets). *The Cartesian product of any two finite sets is itself finite, that is,*

$$\forall A, B\,([A \text{ is finite } \wedge \ B \text{ is finite}] \Rightarrow A \times B \text{ is finite}). \quad (4.568)$$

Exercise 4.36. Prove Theorem 4.121.

(Hint: Use (2.310), (3.27) and (4.563).)

In the following, we establish the equivalence of two-fold Cartesian products $(A \times B) \times C$ and $A \times (B \times C)$ as well as of 'reversed' Cartesian products $A \times B$ and $B \times A$.

Proposition 4.122. *The following sentences are true for any finite sets A, B and C.*

a) There exists a unique set $\bar{f}$ such that an element z is in $\bar{f}$ iff z is in the Cartesian product of $(A \times B) \times C$ and $A \times (B \times C)$ and moreover if z is for some constants a, b and c the ordered pair formed by the ordered triples $((a, b), c)$ and $(a, (b, c))$, that is,

$$\exists! \bar{f}\, \forall z\,(z \in \bar{f} \Leftrightarrow [z \in [(A \times B) \times C] \times [A \times (B \times C)] \\ \wedge \exists a, b, c\,(z = (((a, b), c), (a, (b, c))))]), \quad (4.569)$$

and this set is a function from $(A \times B) \times C$ to $A \times (B \times C)$, that is,

$$\bar{f} : (A \times B) \times C \to A \times (B \times C). \quad (4.570)$$

b) The function $\bar{f}$ is a surjection from $A \times B$ to $B \times A$, that is,

$$\bar{f} : (A \times B) \times C \twoheadrightarrow A \times (B \times C). \quad (4.571)$$

c) *The surjection $\bar{f}$ is an injection from $A \times B$ to $B \times A$, that is,*

$$\bar{f} : (A \times B) \times C \hookrightarrow A \times (B \times C). \tag{4.572}$$

d) *The Cartesian products $(A\times B)\times C$ and $A\times(B\times C)$ are equinumerous, that is,*

$$|(A \times B) \times C| = |A \times (B \times C)|. \tag{4.573}$$

Proof. Letting A, B and C be arbitrary sets and assuming these sets to be finite, we establish in a) – d) a bijection $\bar{f}$ from $(A\times B)\times C$ to $A\times(B\times C)$. We will then also utilize that fact that the finiteness of A, B and C implies first the finiteness of the Cartesian products $A \times B$ and $B \times C$, and then also the finiteness of the Cartesian products $(A \times B) \times C$ and $A \times (B \times C)$ in view of Theorem 4.121.

Concerning a), we apply the Axiom of Specification and the Equality Criterion for sets (in analogy to the proof of Theorem 2.15) to obtain the true uniquely existential sentence (4.569). Thus, the unique set $\bar{f}$ satisfies

$$\begin{aligned} \forall z\,(z \in \bar{f} \Leftrightarrow [z \in [(A \times B) \times C] \times [A \times (B \times C)] \\ \wedge\ \exists a, b, c\,(z = (((a, b), c), (a, (b, c))))]). \end{aligned} \tag{4.574}$$

Thus, $z \in \bar{f}$ implies in particular $z \in [(A \times B) \times C] \times [A \times (B \times C)]$ for any z, so that $\bar{f}$ may be viewed as a binary relation included in $[(A\times B)\times C]\times[A\times(B\times C)]$ (applying the definitions of a binary relation and of a subset). We now prove that the binary relation $\bar{f}$ is a function from $(A \times B) \times C$ to $A \times (B \times C)$ by applying the Function Criterion, i.e. by verifying

$$\forall x\,(x \in (A \times B) \times C \Rightarrow \exists! y\,(y \in A \times (B \times C) \wedge (x, y) \in \bar{f})). \tag{4.575}$$

We let $\bar{x}$ be arbitrary and assume $\bar{x} \in (A \times B) \times C$ to be true, so that there exist by definition of the Cartesian product of two sets constants, say $\bar{u}$ and $\bar{c}$, such that $\bar{u} \in A \times B$, $\bar{c} \in C$ and $(\bar{u}, \bar{c}) = \bar{x}$ hold. Then, $\bar{u} \in A\times B$ implies (again by definition of the Cartesian product of two sets) that there are elements, say $\bar{a}$ and $\bar{b}$, with $\bar{a} \in A$, $\bar{b} \in B$ and $(\bar{a}, \bar{b}) = \bar{u}$; thus, $\bar{x} = ((\bar{a}, \bar{b}), \bar{c})$. We now establish the existential part of the uniquely existential sentence in (4.575). To begin with, $\bar{b} \in B$ and $\bar{c} \in C$ evidently imply that that the ordered pair $\bar{v} = (\bar{b}, \bar{c})$ is in the Cartesian product of B and C, that is, $\bar{v} \in B \times C$. Furthermore, the truth of $\bar{a} \in A$ and $\bar{v} \in B \times C$ clearly shows that the ordered pair $\bar{y} = (\bar{a}, \bar{v})$ is in the Cartesian product of A and $B \times C$, which means that $\bar{y} \in A \times (B \times C)$ holds. Then, since $\bar{x} \in (A \times B) \times C$ and $\bar{y} \in A \times (B \times C)$ are both true, it follows that the ordered pair

$$\bar{z} = (\bar{x}, \bar{y}) = (((\bar{a}, \bar{b}), \bar{c}), (\bar{a}, (\bar{b}, \bar{c})) \tag{4.576}$$

is in the Cartesian product of $(A \times B) \times C$ and $A \times (B \times C)$, that is,

$$\bar{z} \in [(A \times B) \times C] \times [A \times (B \times C)]. \tag{4.577}$$

The equations (4.576) show that there exist constants a, b and c such that $\bar{z} = (((a,b),c),(a,(b,c)))$ holds, which existential sentence implies now – together with (4.577) – in view of (4.574) that $[(\bar{x},\bar{y}) =]\ \bar{z} \in \bar{f}$ is true, so that $(\bar{x},\bar{y}) \in \bar{f}$ holds. Together with the previously obtained $\bar{y} \in A \times (B \times C)$, this finding proves the existential sentence

$$\exists y\,(y \in A \times (B \times C)\ \wedge\ (\bar{x},y) \in \bar{f})$$

and thus the existential part of the uniquely existential sentence in (4.575).

Regarding the uniqueness part, we prove

$$\forall y,y'\,([y \in A \times (B \times C)\ \wedge\ (\bar{x},y) \in \bar{f}\ \wedge\ y' \in A \times (B \times C)\ \wedge\ (\bar{x},y') \in \bar{f}] \\ \Rightarrow y = y'). \tag{4.578}$$

We take two arbitrary $\bar{y}$ and $\bar{y}'$ from the set $A \times (B \times C)$ such that $(\bar{x},\bar{y})$ and $(\bar{x},\bar{y}')$ are in $\bar{f}$. On the one hand, $(\bar{x},\bar{y}) \in \bar{f}$ implies with (4.574) in particular that there are constants, say $\bar{a}$, $\bar{b}$ and $\bar{c}$, with $(\bar{x},\bar{y}) = (((\bar{a},\bar{b}),\bar{c}),(\bar{a},(\bar{b},\bar{c})))$, which equation then yields $\bar{x} = ((\bar{a},\bar{b}),\bar{c})$ and $\bar{y} = (\bar{a},(\bar{b},\bar{c}))$ with the Equality Criterion for ordered pairs. On the other hand, $(\bar{x},\bar{y}') \in \bar{f}$ implies with (4.574) in particular that there exist constants, say $\bar{a}'$, $\bar{b}'$ and $\bar{c}'$, such that $(\bar{x},\bar{y}') = (((\bar{a}',\bar{b}'),\bar{c}'),(\bar{a}',(\bar{b}',\bar{c}')))$, with the consequence that

$$[((\bar{a},\bar{b}),\bar{c}) =]\quad \bar{x} = ((\bar{a}',\bar{b}'),\bar{c}') \tag{4.579}$$

and

$$\bar{y}' = (\bar{a}',(\bar{b}',\bar{c}')) \tag{4.580}$$

hold because of the Equality Criterion for ordered pairs. It follows from (4.579) that $((\bar{a},\bar{b}),\bar{c}) = ((\bar{a}',\bar{b}'),\bar{c}')$ is true, so that further applications of the Equality Criterion for ordered pairs give first $(\bar{a},\bar{b}) = (\bar{a}',\bar{b}')$ and $\bar{c} = \bar{c}'$, and subsequently $\bar{a} = \bar{a}'$ as well as $\bar{b} = \bar{b}'$. Therefore, (4.580) becomes after performing substitutions

$$\bar{y}' = (\bar{a},(\bar{b},\bar{c})) = \bar{y},$$

so that the desired $\bar{y} = \bar{y}'$ follows to be true. As $\bar{y}$ and $\bar{y}'$ are arbitrary, the universal sentence (4.578) follows to be true, completing the proof of the uniquely existential sentence in (4.575). Since $\bar{x}$ is also arbitrary, we may therefore conclude that (4.575) holds, so that $\bar{f}$ is a function from $(A \times B) \times C$ to $A \times (B \times C)$ because of the Function Criterion.

Concerning b), we now apply the Surjection Criterion to prove that $\bar{f}$: $(A \times B) \times C \to A \times (B \times C)$ is a surjection. For this purpose, we verify

$$\forall y \, (y \in A \times (B \times C) \Rightarrow \exists x \, (\bar{f}(x) = y)). \tag{4.581}$$

To do this, we let $\bar{y}$ be arbitrary and assume $\bar{y} \in A \times (B \times C)$ to hold, so that there exist (by definition of the Cartesian product of two sets) constants, say $\bar{a}$ and $\bar{v}$, with $\bar{a} \in A$, $\bar{v} \in B \times C$ and $(\bar{a}, \bar{v}) = \bar{y}$. Then, $\bar{v} \in B \times C$ implies (again by definition of the Cartesian product of two sets) that there are elements, say $\bar{b}$ and $\bar{c}$, satisfying $\bar{b} \in B$, $\bar{c} \in C$ and $(\bar{b}, \bar{c}) = \bar{v}$. We therefore obtain the identity $\bar{y} = (\bar{a}, (\bar{b}, \bar{c}))$. The ordered pair $\bar{u} = (\bar{a}, \bar{b})$ is then also specified, so that the conjunction of $\bar{a} \in A$ and $\bar{b} \in B$ evidently gives $\bar{u} \in A \times B$. With this, the ordered pair

$$\bar{x} = (\bar{u}, \bar{c}) = ((\bar{a}, \bar{b}), \bar{c})$$

exists also, and therefore the conjunction of $\bar{u} \in A \times B$ and $\bar{c} \in C$ yields $\bar{x} \in (A \times B) \times C$. This in turn implies with (4.575) the unique existence of the element $y \in A \times (B \times C)$ with $(\bar{x}, y) \in \bar{\bar{c}}$. It then follows with (4.574) in particular that there exist elements, say $\bar{\bar{a}}$, $\bar{\bar{b}}$ and $\bar{\bar{c}}$, such that $(\bar{x}, y) = (((\bar{\bar{a}}, \bar{\bar{b}}), \bar{\bar{c}}), (\bar{\bar{a}}, (\bar{\bar{b}}, \bar{\bar{c}})))$. Consequently, we obtain with the Equality Criterion for ordered pairs

$$[((\bar{a}, \bar{b}), \bar{c}) =] \quad \bar{x} = ((\bar{\bar{a}}, \bar{\bar{b}}), \bar{\bar{c}}) \tag{4.582}$$

and

$$y = (\bar{\bar{a}}, (\bar{\bar{b}}, \bar{\bar{c}})). \tag{4.583}$$

The equations in (4.582) yield $((\bar{a}, \bar{b}), \bar{c}) = ((\bar{\bar{a}}, \bar{\bar{b}}), \bar{\bar{c}})$ and therefore evidently first $(\bar{a}, \bar{b}) = (\bar{\bar{a}}, \bar{\bar{b}})$ as well as $\bar{c} = \bar{\bar{c}}$, and then $\bar{a} = \bar{\bar{a}}$ as well as $\bar{b} = \bar{\bar{b}}$. With these two equations, (4.583) can be written equivalently as

$$y = (\bar{a}, (\bar{b}, \bar{c})) \quad [= \bar{y}].$$

Thus, $y = \bar{y}$ holds, and therefore the previously found $(\bar{x}, y) \in \bar{c}$ yields $(\bar{x}, \bar{y}) \in \bar{f}$, which we may write also as $\bar{f}(\bar{x}) = \bar{y}$. This equation shows that the existential sentence in (4.581) is true, and since $\bar{y}$ was arbitrary, the universal sentence (4.581) follows to be true. This shows in light of the Surjection Criterion that the function $\bar{f} : (A \times B) \times C \to A \times (B \times C)$ is indeed a surjection.

Concerning c), the next task is to prove that $\bar{f} : (A \times B) \times C \to A \times (B \times C)$ is an injection. To do this, we demonstrate the truth of

$$\forall x, x' \, ([x, x' \in (A \times B) \times C \, \wedge \, \bar{f}(x) = \bar{f}(x')] \Rightarrow x = x'). \tag{4.584}$$

We let x and x' be arbitrary elements of $(A\times B)\times C$ such that $[y=]\ \bar{f}(x) = \bar{f}(x')$, which equations we may then also write as $(x,y)\in\bar{f}$ and $(x',y)\in\bar{f}$. On the one hand, $(x,y)\in\bar{f}$ implies with (4.574) in particular that there are elements, say $\bar{a}$, $\bar{b}$ and $\bar{c}$, such that $(x,y) = (((\bar{a},\bar{b}),\bar{c}),(\bar{a},(\bar{b},\bar{c})))$ is true, which equation then gives $x = ((\bar{a},\bar{b}),\bar{c})$ and $y = (\bar{a},(\bar{b},\bar{c}))$ with the Equality Criterion for ordered pairs. On the other hand, $(x',y)\in\bar{f}$ implies again with (4.574) that there exist elements, say $\bar{a}'$, $\bar{b}'$ and $\bar{c}'$, with $(x',y) = (((\bar{a}',\bar{b}'),\bar{c}'),(\bar{a}',(\bar{b}',\bar{c}')))$, and this equation yields

$$x' = ((\bar{a}',\bar{b}'),\bar{c}') \tag{4.585}$$

and

$$[(\bar{a},(\bar{b},\bar{c}))=]\quad y = (\bar{a}',(\bar{b}',\bar{c}')),$$

again (3.3) with the Equality Criterion for ordered pairs. The latter gives $(\bar{a},(\bar{b},\bar{c})) = (\bar{a}',(\bar{b}',\bar{c}'))$ and therefore first $\bar{a}=\bar{a}'$ as well as $(\bar{b},\bar{c}) = (\bar{b}',\bar{c}')$, and then $\bar{b}=\bar{b}'$ as well as $\bar{c}=\bar{c}'$. Carrying out substitutions in (4.585) based on the preceding equations, we obtain

$$x' = ((\bar{a},\bar{b}),\bar{c})\quad [=x]$$

and therefore the desired equality $x = x'$. As x and x' were arbitrary, we may therefore conclude that (4.584) holds, so that the surjection $\bar{f} : (A\times B)\times C \twoheadrightarrow A\times(B\times C)$ is also an injection from $(A\times B)\times C$ to $A\times(B\times C)$.

Concerning d), we observe that $\bar{f}$ is an injection as well as a surjection, and thus a bijection from $(A\times B)\times C$ to $A\times(B\times C)$. We thus established the existence of a bijection from the finite set $(A\times B)\times C$ to the finite set $A\times(B\times C)$, so that $|(A\times B)\times C| = |A\times(B\times C)|$ follows to be true with Proposition 4.107.

Then, since A, B and C were arbitrary, we may finally conclude that the proposition is true. □

Exercise 4.37. Show that the following sentences are true for any finite sets A and B.

a) There exists a unique set $\bar{g}$ such that an element z is in $\bar{g}$ iff z is in the Cartesian product of $A\times B$ and $B\times A$ and moreover if z is for some constants a and b the ordered pair formed by the ordered pairs (a,b) and (b,a), that is,

$$\exists!\bar{g}\,\forall z\,(z\in\bar{g}\Leftrightarrow[z\in(A\times B)\times(B\times A)\wedge\exists a,b\,(z=((a,b),(b,a)))]), \tag{4.586}$$

and this set is a function from $A\times B$ to $B\times A$, i.e.

$$\bar{g} : A\times B\to B\times A. \tag{4.587}$$

b) The function $\bar{g}$ is a surjection from $A \times B$ to $B \times A$, i.e.

$$\bar{g} : A \times B \twoheadrightarrow B \times A. \tag{4.588}$$

c) The surjection $\bar{g}$ is an injection from $A \times B$ to $B \times A$, i.e.

$$\bar{g} : A \times B \hookrightarrow B \times A. \tag{4.589}$$

d) The Cartesian product of A and B and the Cartesian product of B and A are equinumerous, that is,

$$|A \times B| = |B \times A|. \tag{4.590}$$

(Hint: Proceed in analogy to the proof of Proposition 4.122.)

Lemma 4.123. *For any set A it is true that,*

a) if A is finite, then there exist a natural number n and a surjection from the initial segment of $\mathbb{N}_+$ up to n to A, i.e.

$$A \text{ is finite } \Rightarrow \exists n, f\,(n \in \mathbb{N} \wedge f : \{1, \ldots, n\} \twoheadrightarrow A). \tag{4.591}$$

b) if there exist a natural number n and a surjection from the initial segment of $\mathbb{N}_+$ up to n to A, then there exist a natural number n and an injection from A to the initial segment of $\mathbb{N}_+$ up to n, i.e.

$$\begin{aligned} &\exists n, f\,(n \in \mathbb{N} \wedge f : \{1, \ldots, n\} \twoheadrightarrow A) \\ &\quad \Rightarrow \exists n, f\,(n \in \mathbb{N} \wedge f : A \hookrightarrow \{1, \ldots, n\}). \end{aligned} \tag{4.592}$$

Proof. We let A be an arbitrary set. Concerning a), we assume that A is finite. By definition of a finite set, there then exist a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to A, say $\bar{c}$. Thus, $\bar{c}$ is in particular a surjection from $\{1, \ldots, \bar{n}\}$ to A (by definition of a bijection), so that the existential sentence in (4.591) is true, completing the proof of the implication a).

Regarding b), we assume that there exist a natural number, say $\bar{n}$, and a surjection from $\{1, \ldots, \bar{n}\}$ to A, say $\bar{f}$. Thus, $\mathrm{ran}(\bar{f}) = A$ holds by definition of a surjection. We now prove the desired consequent by cases, based on the fact that the disjunction of $\bar{n} = 0$ and $\bar{n} \in \mathbb{N}_+$ holds according to (2.310).

The first case $\bar{n} = 0$ implies $\mathrm{dom}(\bar{f}) = \{1, \ldots, \bar{n}\} = \emptyset$ according to the notation for the empty initial segment of $\mathbb{N}_+$, and therefore $A = \mathrm{ran}(\bar{f}) = \emptyset$

with (3.119), so that $\bar{f}$ is an injection from $\emptyset$ to $\emptyset$ because of Exercise 3.76. We may write this injection via substitution also as $\bar{f} : A \hookrightarrow \{1, \ldots, \bar{n}\}$. Since $\bar{n}$ is a natural number we have that the consequent of the implication (4.601) holds (in case of $\bar{n} = 0$).

The second case $\bar{n} \in \mathbb{N}_+$ shows that the domain $\{1, \ldots, \bar{n}\}$ of $\bar{f}$ is now nonempty (by definition of an initial segment of $\mathbb{N}_+$), which implies with (3.119) that the range A of $\bar{f}$ is also nonempty. We now define the function

$$g : A \to \{1, \ldots, \bar{n}\}, \qquad a \mapsto g(a) = \min \bar{f}^{-1}[\{a\}]. \tag{4.593}$$

replacement. To do this, we verify

$$\forall a\, (a \in A \Rightarrow \exists! m\, (m = \min \bar{f}^{-1}[\{a\}])), \tag{4.594}$$

letting $a \in A$ be arbitrary. We first notice that, since $\bar{f}$ is a surjection, the inverse image $\bar{f}^{-1}[\{a\}]$ is nonempty according to Proposition 3.226; furthermore, as $\bar{f}^{-1}[\{a\}]$ is (by definition of an inverse image) a subset of the domain $\{1, \ldots, \bar{n}\}$ of $\bar{f}$, we see in light of (4.284) that the least element of the inverse image exists. Consequently, the uniquely existential sentence in (4.593) follows to be true with Proposition 4.594, and since a was arbitrary, we may therefore conclude that (4.594) holds. This universal sentence implies then that there exists a unique function g with domain A such that $g(a) = \min \bar{f}^{-1}[\{a\}]$ holds for any $a \in A$. As every inverse image $\bar{f}^{-1}[\{a\}]$ is a subset of $\{1, \ldots, \bar{n}\}$, it follows by definition of a least element for any $a \in A$ that the unique function value $g(a)$ is an element of $\{1, \ldots, \bar{n}\}$. Thus, g is according to the Function Criterion a function from A to $\{1, \ldots, \bar{n}\}$, which we may write as (4.594).

We now apply the Injection Criterion and verify that g is an injection, i.e. that g satisfies

$$\forall a, a'\, ([a, a' \in A \wedge a \neq a'] \Rightarrow g(a) \neq g(a')). \tag{4.595}$$

To do this, we let a and a' be arbitrary distinct elements of A and show that this implies $g(a) \neq g(a')$. Here, $a \neq a'$ implies $\{a\} \cap \{a'\} = \emptyset$ with (2.174). We therefore obtain the equations

$$\begin{aligned} \emptyset &= \bar{f}^{-1}[\emptyset] \\ &= \bar{f}^{-1}[\{a\} \cap \{a'\}] \\ &= \bar{f}^{-1}[\{a\}] \cap \bar{f}^{-1}[\{a'\}], \end{aligned}$$

by applying Exercise 3.90a), then substitution, and finally Exercise 3.106. Consequently,

$$\forall y\, (\neg y \in \bar{f}^{-1}[\{a\}] \cap \bar{f}^{-1}[\{a'\}]) \tag{4.596}$$

holds by definition of the empty set. We now demonstrate that this finding implies the truth of the universal sentence

$$\forall y\,(\neg y \in \bar{f}^{-1}[\{a\}] \,\vee\, \neg y \in \bar{f}^{-1}[\{a'\}]). \tag{4.597}$$

Taking an arbitrary y, the negation in (4.596) implies the disjunction in (4.597) with the definition of the intersection of two sets and De Morgan's Law for sentences (1.51); since y is arbitrary, we may therefore infer from this indeed the truth of (4.597). Now, by definition of a least element, we have the true sentence

$$\min \bar{f}^{-1}[\{a\}] \in \bar{f}^{-1}[\{a\}], \tag{4.598}$$

which in turn implies with (4.597) the truth of the negation

$$\neg \min \bar{f}^{-1}[\{a'\}] \in \bar{f}^{-1}[\{a\}]. \tag{4.599}$$

The conjunction of (4.598) and (4.599) gives the inequality

$$\min \bar{f}^{-1}[\{a\}] \neq \min \bar{f}^{-1}[\{a'\}]$$

with (2.4), which yields the desired $g(a) \neq g(a')$ with the definition of the function g in (4.593). As a and a' were arbitrary, we may therefore conclude that (4.595) is true, so that the function $g : A \to \{1, \ldots, \bar{n}\}$ is an injection. Since $\bar{n}$ is a natural number, the existential sentence on the right-hand side of the implication (4.592) holds therefore also in the second case, which completes the proof of b) by cases. □

Theorem 4.124 (Finiteness Criteria). *For any set A it is true that*

a) *A is finite iff there exists a natural number n and a surjection from the initial segment of $\mathbb{N}_+$ up to n to A, i.e.*

$$A \text{ is finite} \;\Leftrightarrow\; \exists n, f\,(n \in \mathbb{N} \,\wedge\, f : \{1, \ldots, n\} \twoheadrightarrow A). \tag{4.600}$$

b) *A is finite iff there exists a natural number n and an injection from A to the initial segment of $\mathbb{N}_+$ up to n, i.e.*

$$A \text{ is finite} \;\Leftrightarrow\; \exists n, f\,(n \in \mathbb{N} \,\wedge\, f : A \hookrightarrow \{1, \ldots, n\}). \tag{4.601}$$

Proof. We let A be an arbitrary set and observe that the first part ('$\Rightarrow$') of the equivalence a) holds in light of (4.591). Furthermore, because the conjunction of (4.591) and (4.592) is true, it then follows with the Law of the Hypothetical Syllogism that the first part ('$\Rightarrow$') of the equivalence (4.601) holds as well.

We now prove the second part ('$\Leftarrow$') of the equivalence (4.601), assuming that there exist a natural number, say $\bar{n}$, and an injection from A to $\{1,\ldots,\bar{n}\}$, say $\bar{f}: A \hookrightarrow \{1,\ldots,\bar{n}\}$. Here, the initial segment $\{1,\ldots,\bar{n}\}$ is a finite set due to Exercise 4.34. Moreover, it follows with Corollary 3.204 that $\bar{f}: A \to \mathrm{ran}(\bar{f})$ is a bijection, where $\mathrm{ran}(\bar{f}) \subseteq \{1,\ldots,\bar{n}\}$ holds by definition of a range. Consequently, the disjunction

$$\mathrm{ran}(\bar{f}) \subset \{1,\ldots,\bar{n}\} \vee \mathrm{ran}(\bar{f}) = \{1,\ldots,\bar{n}\} \tag{4.602}$$

holds with (2.26), which we now use prove by cases that A is a finite set.

The first case $\mathrm{ran}(\bar{f}) \subset \{1,\ldots,\bar{n}\}$ implies together with the finiteness of $\{1,\ldots,\bar{n}\}$ that $\mathrm{ran}(\bar{f})$ is a finite set, according to (4.553). This finding in turn implies (by definition of a finite set) that there exist a natural number, say $\bar{N}$, and a bijection from $\{1,\ldots,\bar{N}\}$ to $\mathrm{ran}(\bar{f})$, say

$$\bar{d}: \{1,\ldots,\bar{N}\} \rightleftarrows \mathrm{ran}(\bar{f}).$$

Then, we also have $\bar{N} = |\mathrm{ran}(\bar{f})|$ (by definition of a cardinality). The fact that $\bar{f}: A \to \mathrm{ran}(\bar{f})$ is a bijection implies with Theorem 3.212 that its inverse is the bijection

$$\bar{f}^{-1}: \mathrm{ran}(\bar{f}) \rightleftarrows A.$$

It then follows with Theorem 3.207 that the composition $\bar{f}^{-1} \circ \bar{d}$ is the bijection

$$(\bar{f}^{-1} \circ \bar{d}): \{1,\ldots,\bar{N}\} \rightleftarrows A.$$

Thus, there exist a natural number n and a bijection from $\{1,\ldots,n\}$ to A, so that A is a finite set (in the first case).

The second case $\mathrm{ran}(\bar{f}) = \{1,\ldots,\bar{n}\}$ allows us to apply substitution to the previously established bijection $\bar{f}$ from A to $\mathrm{ran}(\bar{f})$, which we may thus write as $\bar{f}: A \rightleftarrows \{1,\ldots,\bar{n}\}$. Then, we obtain with Theorem 3.212 the bijection

$$\bar{f}^{-1}: \{1,\ldots,\bar{n}\} \rightleftarrows A.$$

Thus, there exist also in this case a natural number n and a bijection from $\{1,\ldots,n\}$ to A, so that A is finite in any case.

This completes the proof of the second part ('$\Leftarrow$') of the equivalence (4.601), so that b) is true. It now remains for us to establish the second part ('$\Leftarrow$') of the equivalence (4.600). For this purpose, we observe that the conjunction of (4.592) and the second part ('$\Leftarrow$') of the equivalence (4.601) is true. We may then apply the Law of the Hypothetical Syllogism again to infer from this true conjunction indeed the truth of the desired second part ('$\Leftarrow$') of the equivalence (4.600), so that a) is also true. Since A was initially arbitrary, we may therefore conclude that the theorem holds, as claimed. $\square$

We demonstrate now the application of the Finiteness Criterion based on the construction of a surjection.

Corollary 4.125. *It is true for any set Y and any natural number n that the range of any sequence in $Y^{\{1,\ldots,n\}}$ is finite, that is,*

$$\forall Y, s\,([n \in \mathbb{N} \,\wedge\, s \in Y^{\{1,\ldots,n\}}] \Rightarrow \mathrm{ran}(s) \text{ is finite}). \tag{4.603}$$

Proof. We let Y be an arbitrary set, n an arbitrary natural number and s an arbitrary element of $Y^{\{1,\ldots,n\}}$. By definition of this set of functions, we then have $s : \{1,\ldots,n\} \to Y$, and consequently $s : \{1,\ldots,n\} \twoheadrightarrow \mathrm{ran}(s)$ by definition of a surjection. This shows that the existential sentence

$$\exists n, f\,(n \in \mathbb{N} \,\wedge\, f : \{1,\ldots,n\} \twoheadrightarrow Y)$$

is true, which finding implies with the Finiteness Criterion (4.600) that $\mathrm{ran}(s)$ is a finite set. Since Y, n and s were arbitrary, we may therefore conclude that the universal sentence (4.603) holds. $\square$

Recalling that every set of functions $Y^{\{1,\ldots,n\}}$ is identical with the Cartesian power Y^n, as shown by (4.385), we can immediately formulate the preceding corollary also in the following form.

Corollary 4.126. *It is true for any set Y and any natural number n that the range of any element of the n-th Cartesian power of Y is finite, that is,*

$$\forall Y, n, s\,([n \in \mathbb{N} \,\wedge\, s \in Y^n] \Rightarrow \mathrm{ran}(s) \text{ is finite}). \tag{4.604}$$

Corollary 4.127. *It is true for any set Y that the range of any sequence in $Y^{<\mathbb{N}_+}$ is finite, that is,*

$$\forall Y, s\,(s \in Y^{<\mathbb{N}_+} \Rightarrow \mathrm{ran}(s) \text{ is finite}). \tag{4.605}$$

Proof. We let Y be an arbitrary set and s an arbitrary element of $Y^{<\mathbb{N}_+}$. By definition of this set of function (see Exercise 4.32), there is then a particular $\bar{n} \in \mathbb{N}$ with $s \in Y^{\{1,\ldots,\bar{n}\}}$. Thus, $\mathrm{ran}(s)$ follows to be a finite set with (4.603). Since Y and s are arbitrary, we may therefore conclude that (4.605) holds. $\square$

Proposition 4.128. *The domain of any finite binary relation is finite.*

Proof. We let R be an arbitrary set, and we assume R to be both a finite set and a binary relation. The former assumption implies then with the definition of a finite set that there exist sets, say $\bar{n}$ and $\bar{c}$, such that $\bar{n} \in \mathbb{N}$ and

$\bar{c}: \{1, \ldots, \bar{n}\} \rightleftarrows R$. We may now apply Function definition by replacement to establish a unique function f with domain $\{1, \ldots, \bar{n}\}$ satisfying

$$\forall i\,(i \in \{1, \ldots, \bar{n}\} \Rightarrow \exists b\,(\,(i, (f(i), b)) \in \bar{c}\,)). \tag{4.606}$$

For this purpose, we prove the universal sentence

$$\forall i\,(i \in \{1, \ldots, \bar{n}\} \Rightarrow \exists! y\,(\exists b\,(\,(i, (y, b)) \in \bar{c}\,))), \tag{4.607}$$

letting i be arbitrary and assuming $i \in \{1, \ldots, \bar{n}\}$ $[= \mathrm{dom}(\bar{c})]$ to be true. By definition of a domain, there is then a constant, say $\bar{z}$, with $(i, \bar{z}) \in \bar{c}$. According to the definition of a range, we therefore have $\bar{z} \in \mathrm{ran}(\bar{c})$, which range is identical with the codomain R of $\bar{c}$ since the bijection $\bar{c}$ is in particular a surjection. Thus, substitution yields $\bar{z} \in R$, which implies with the definition of a binary relation that there are constants, say $\bar{a}$ and $\bar{b}$, such that $\bar{z} = (\bar{a}, \bar{b})$. With this equation, the previously established $(i, \bar{z}) \in \bar{c}$ gives us $(i, (\bar{a}, \bar{b})) \in \bar{c}$ via substitution. This finding demonstrates the truth of the existential sentence

$$\exists b\,(\,(i, (\bar{a}, b)) \in \bar{c}\,),$$

and this shows in turn that the existential part

$$\exists y\,(\exists b\,(\,(i, (y, b)) \in \bar{c}\,))$$

of the uniquely existential sentence in (4.607). To establish the uniqueness part, we prove

$$\forall y, y'\,([\exists b\,(\,(i, (y, b)) \in \bar{c}\,) \wedge \exists b'\,(\,(i, (y', b')) \in \bar{c}\,)] \Rightarrow y = y'), \tag{4.608}$$

letting y and y' be arbitrary and assuming the existence of particular constants $\bar{b}$ and $\bar{b}'$ satisfying $(i, (y, \bar{b})) \in \bar{c}$ as well as $(i, (y', \bar{b}'))$. Since $\bar{c}$ is a function, the conjunction of the latter two findings implies $(y, \bar{b}) = (y', \bar{b}')$, and this equation further implies $y = y'$ with the Equality Criterion for ordered pairs. As y and y' were arbitrary, we may now infer from the truth of this equation the truth of the (4.608) and consequently the truth of the uniquely existential sentence in (4.607). Here, i was arbitrary, so that the universal sentence (4.607) follows to be also true. This in turn implies the existence of a unique function f having the domain $\{1, \ldots, \bar{n}\}$ and the definite property (4.606).

Next, we prove that the domain of R is given by the range of f, by demonstrating the truth of the universal sentence

$$\forall y\,(y \in \mathrm{ran}(f) \Leftrightarrow y \in \mathrm{dom}(R)). \tag{4.609}$$

We take an arbitrary y and assume first $y \in \mathrm{ran}(f)$ to be true, so that the definition of a range gives us a particular constant $\bar{k}$ such that $(\bar{k}, y) \in f$ holds. Here, the definition of a domain shows that $\bar{k} \in \{1, \ldots, \bar{n}\}$ [$=$ $\mathrm{dom}(f)$] is true, which in turn implies with (4.606) the existence of a particular constant $\bar{b}$ such that $(\bar{k}, (f(\bar{k}), \bar{b})) \in \bar{c}$. Using again the definition of a range, we obtain then $(f(\bar{k}), \bar{b}) \in \mathrm{ran}(\bar{c})$ [$= R$], so that $f(\bar{k}) \in \mathrm{dom}(R)$ follows to be true by definition of a domain. Observing now that $(\bar{k}, y) \in f$ can be written in function notation as $y = f(\bar{k})$, we arrive at the desired consequent $y \in \mathrm{dom}(R)$ by means of substitution. We thus proved the implication '$\Rightarrow$' in (4.609).

To establish the converse implication '$\Leftarrow$', we now assume $y \in \mathrm{dom}(R)$ to be true, with the evident consequence that $(y, \bar{b}) \in R$ [$= \mathrm{ran}(\bar{c})$] holds for a particular constant $\bar{b}$. We therefore have also $(\bar{k}, (y, \bar{b})) \in \bar{c}$ for a particular constant $\bar{k}$, and this constant is thus in the domain $\{1, \ldots, \bar{n}\}$ of $\bar{c}$. According to (4.606), $\bar{k} \in \{1, \ldots, \bar{n}\}$ implies $(\bar{k}, (f(\bar{k}), \bar{b}')) \in \bar{c}$ for some particular constant $\bar{b}'$, which yields in conjunction with the preceding finding $(\bar{k}, (y, \bar{b})) \in \bar{c}$ the truth of $(f(\bar{k}), \bar{b}') = (y, \bar{b})$, because $\bar{c}$ is a function. Consequently, we obtain with the Equality Criterion for ordered pairs especially the equation $f(\bar{k}) = y$, which we may write in the form $(\bar{k}, y) \in f$. This shows that y is an element of the range of f, so that the implication '$\Leftarrow$' holds as well.

Having thus completed the proof of the equivalence in (4.609), we may now infer from this the truth of the universal sentence (4.609), since y was arbitrary, and subsequently the truth of the proposed equation $\mathrm{ran}(f) = \mathrm{dom}(R)$. This finding demonstrates that f is a surjection from $\{1, \ldots, \bar{n}\}$ to $\mathrm{dom}(R)$ and therefore that the existential sentence

$$\exists n, f\, (n \in \mathbb{N} \wedge f : \{1, \ldots, n\} \twoheadrightarrow \mathrm{dom}(R))$$

holds. It then follows with the Finiteness Criterion (4.600) that $\mathrm{dom}(R)$ is a finite set, and as R was arbitrary here, we may therefore conclude that the proposed universal sentence is true. □

Exercise 4.38. Prove that the range of any finite binary relation is finite.

(Hint: Proceed in analogy to the proof of Proposition 4.128.)

Exercise 4.39. Prove that the range of any function is finite if its domain is finite.

(Hint: Apply (4.600) in connection with Definition 3.48 and (3.649).)

Exercise 4.40. Apply Theorem 4.124b) to show that any subset of any finite set is itself finite, i.e.

$$\forall A, B\, (A \subseteq B \Rightarrow [B \text{ is finite } \Rightarrow A \text{ is finite}]). \tag{4.610}$$

(Hint: Use (3.624).)

We will also apply the following alternative formulations of the Finiteness Criteria.

Theorem 4.129 (Finiteness Criteria (variant)). *For any set A it is true that*

a) A is finite iff there exists a natural number n and a surjection from n to A, i.e.

$$A \text{ is finite} \;\Leftrightarrow\; \exists n, f\,(n \in \mathbb{N} \,\wedge\, f : n \twoheadrightarrow A). \tag{4.611}$$

b) A is finite iff there exists a natural number n and an injection from A to to n, i.e.

$$A \text{ is finite} \;\Leftrightarrow\; \exists n, f\,(n \in \mathbb{N} \,\wedge\, f : A \hookrightarrow n). \tag{4.612}$$

Proof. We let A be an arbitrary set. Concerning a), to prove the first part ('$\Rightarrow$') of the equivalence, we assume that A is finite, which implies with (4.600) that there exists a natural number, say $\bar{n}$, and a surjection from $\{1, \ldots, \bar{n}\}$ to A, say

$$\bar{f} : \{1, \ldots, \bar{n}\} \twoheadrightarrow A.$$

Then, we have the bijection $s^+ \restriction \bar{n}$ from $\bar{n}$ to $\{1, \ldots, \bar{n}\}$ according to (4.465), which is in particular a surjection, i.e.

$$s^+ \restriction \bar{n} : \bar{n} \twoheadrightarrow \{1, \ldots, \bar{n}\}.$$

It now follows with Theorem 3.199 that the composition of the surjections $\bar{f}$ and $s^+ \restriction \bar{n}$ is itself a surjection, that is,

$$\bar{f} \circ (s^+ \restriction \bar{n}) : \bar{n} \twoheadrightarrow A.$$

This proves the existence of a natural number n and of a surjection f from n to A, and thus the first part of the equivalence (4.611).

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume the existential sentence in (4.611) to be true, so that there is a natural number, say $\bar{m}$, and a surjection from $\bar{m}$ to A, say

$$\bar{g} : \bar{m} \twoheadrightarrow A.$$

We then have the bijection $(s^+ \restriction \bar{m})^{-1}$ from $\{1, \ldots, \bar{m}\}$ to $\bar{m}$ due to (4.466), which is thus a surjection, i.e.

$$(s^+ \restriction \bar{m})^{-1} : \{1, \ldots, \bar{m}\} \twoheadrightarrow \bar{m}.$$

Therefore, the composition of the surjections $\bar{g}$ and $(s^+ \restriction \bar{n})^{-1}$ is itself a surjection, that is,

$$\bar{g} \circ (s^+ \restriction \bar{n})^{-1} : \{1, \ldots, \bar{m}\} \twoheadrightarrow A.$$

This evidently proves the existential sentence in (4.600), which then implies that A is finite. Since A was arbitrary, we may therefore conclude that a) holds. □

Exercise 4.41. Establish Part b) of Theorem 4.129.

(Hint: Proceed in analogy to the proof of Part a) and use now Theorem 3.190.)

Exercise 4.42. Show for any set Y that the range of any sequence in $Y^{<\mathbb{N}}$ is finite, that is,

$$\forall Y, s\,(s \in Y^{<\mathbb{N}} \Rightarrow \mathrm{ran}(s) \text{ is finite}). \tag{4.613}$$

(Hint: Proceed similarly as in the proof of Corollary 4.125, using now Proposition 4.86) and (4.611).)

Note 4.23. The preceding Corollary shows, for any Y, that any sequence $s : n \to Y$ in $Y^{<\mathbb{N}}$ has a finite number of terms. We therefore call $Y^{<\mathbb{N}}$ also the *set of finite sequences* in Y.

4.7.2. Infinite sets

Exercise 4.43. Show that an infinite set is nonempty, that is,

$$\forall A\,(A \text{ is infinite } \Rightarrow A \neq \emptyset). \tag{4.614}$$

(Hint: Prove the implication by contradiction.)

Exercise 4.44. Show that any set that includes an infinite set is itself infinite, i.e.

$$\forall A, B\,(A \subseteq B \Rightarrow [A \text{ is infinite } \Rightarrow B \text{ is infinite}]). \tag{4.615}$$

(Hint: Use (4.610).)

Proposition 4.130. *The difference of an infinite set A and a finite subset of A is infinite, that is,*

$$\forall A, B\,([A \text{ is infinite } \wedge\ B \text{ is finite } \wedge\ B \subseteq A] \Rightarrow A \setminus B \text{ is infinite}). \tag{4.616}$$

Proof. We let A and B be arbitrary and prove the implication by contradiction, assuming that A is infinite, that B is a finite subset of A, and that $A \setminus B$ is finite. The finiteness of $A \setminus B$ and of B then implies with (4.545) that the union $(A \setminus B) \cup B$ is finite. As the assumption $B \subseteq A$ implies $(A \setminus B) \cup B = A$ with (2.263), it follows from the finiteness of $(A \setminus B) \cup B$ that A is finite, which contradicts the assumption that A is infinite. This proves the implication in (4.616), and since A and B were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

We now demonstrate that an infinite subset A of $\mathbb{N}$ can be 'sorted' in such a way that the first element of the sorted set is the least element of A, the second element the second lowest element of A, etc. This sorting will accordingly be expressed as an increasing function, where every natural number n is associated with the n-th lowest element of A. We first define the ranking of an arbitrary (finite or infinite) set.

Definition 4.15 (Ranking of a set, rank of an element). For any linearly ordered set $(A, <_A)$ we say that

(1) a set R is a *strict ranking* of A iff R is a strictly increasing bijective sequence in A.

(2) a set R is a *ranking* of A iff R is an increasing surjective sequence in A.

We then call any index i of R the *rank* of $R(i)$.

Lemma 4.131 (Ranking of an infinite subset of $\mathbb{N}$). *The following sentences are true for any infinite subset A of $\mathbb{N}$.*

a) There exists a unique function

$$F : A^{<\mathbb{N}} \to A, \qquad s \mapsto \min[A \setminus \operatorname{ran}(s)]. \tag{4.617}$$

b) Then, there exists a unique sequence

$$f : \mathbb{N} \to A, \qquad n \mapsto f_n = \min[A \setminus \operatorname{ran}(f \restriction n)]. \tag{4.618}$$

c) The sequence f is an injection, that is,

$$f : \mathbb{N} \hookrightarrow A. \tag{4.619}$$

d) The sequence f is strictly increasing.

e) Every term of the sequence f is greater than or equal to its index, i.e.

$$\forall n \, (n \in \mathbb{N} \Rightarrow n \leq f_n). \tag{4.620}$$

f) The sequence f is a surjection, that is,

$$f : \mathbb{N} \twoheadrightarrow A. \tag{4.621}$$

g) The sequence f is a strict ranking of A.

Proof. We let A be an arbitrary set, we assume that A is infinite, and we assume moreover that $A \subseteq \mathbb{N}$ holds.

Concerning a), we define the function F by replacement, letting $\varphi(s, m)$ be the formula

$$m = \min[A \setminus \operatorname{ran}(s)] \tag{4.622}$$

and verifying

$$\forall s \, (s \in A^{<\mathbb{N}} \Rightarrow \exists! m \, (\varphi(s, m))). \tag{4.623}$$

To prove this universal sentence, we let s be arbitrary and assume s to be an element of $A^{<\mathbb{N}}$ (so that s is a finite sequence in A). Then, $s \in A^{<\mathbb{N}}$ implies with (4.613) that $\operatorname{ran}(s)$ is a finite set. Furthermore, since A is codomain of s, the inclusion $\operatorname{ran}(s) \subseteq A$ holds. Now, as $\operatorname{ran}(s)$ a finite subset of the infinite set A, it follows with (4.616) that the set difference $A \setminus \operatorname{ran}(s)$ is an infinite set, and this further implies $A \setminus \operatorname{ran}(s) \neq \emptyset$ with (4.614). Observing that the inclusions

$$A \setminus \operatorname{ran}(s) \subseteq A \subseteq \mathbb{N} \tag{4.624}$$

hold with (2.125) and the initial assumption, we then see in view of the transitivity (2.13) of $\subseteq$ that the nonempty set difference $A \setminus \operatorname{ran}(s)$ is a subset of $\mathbb{N}$. Since $(\mathbb{N}, \leq)$ is a well-ordered set according to Corollary 4.45, it follows that the minimum of $A \setminus \operatorname{ran}(s)$ exists (see also Corollary 4.44). Thus, the existential part of the uniquely existential sentence in (4.623) holds. Now, the range of s is a uniquely specified set, and the set difference of A and this range is also uniquely specified. Moreover, the minimum of this set difference is a unique element of that set difference. Consequently, there exists a unique m such that m is identical with that minimum, which proves the uniqueness part. Let us also notice that this minimum is then by definition an element of $A \setminus \operatorname{ran}(s)$, which further implies

$$\min[A \setminus \operatorname{ran}(s)] \in A \tag{4.625}$$

with the first inclusion in (4.624), applying the definition of a subset. Since s is arbitrary, we may therefore conclude that (4.623) is true and furthermore that (4.625) holds for all $s \in A^{<\mathbb{N}}$. It then follows with Theorem 3.160 that there exists a unique function F with domain $A^{<\mathbb{N}}$ satisfying

$$\forall s \, (s \in A^{<\mathbb{N}} \Rightarrow F(s) = \min[A \setminus \operatorname{ran}(s)]).$$

Since all of the values of F are in A, as noted previously, it also follows with the Function Criterion that A is codomain of F, so that we obtained the desired mapping (4.617).

Concerning b), we observe in light of the Strong Recursion Theorem and Corollary 4.97 that the function (4.617) implies the unique existence of a sequence $f = (f_n)_{n\in\mathbb{N}}$ in A such that

$$f_n = F(f \upharpoonright n) = \min[A \setminus \operatorname{ran}(f \upharpoonright n)] \tag{4.626}$$

holds for all $n \in \mathbb{N}$, which sequence we may evidently write as (4.618). Let us observe here that A is a codomain of f, so that $\operatorname{ran}(f) \subseteq A$ holds. Together with initial assumption $A \subseteq \mathbb{N}$, this implies $\operatorname{ran}(f) \subseteq \mathbb{N}$ with the transitivity (2.13) of $\subseteq$, which inclusion shows that $\mathbb{N}$ is also a codomain of f.

Concerning c), we prove that $f : \mathbb{N} \to A$ is an injection by applying the Injection Criterion, i.e. by verifying

$$\forall m, n\,([m, n \in \mathbb{N} \wedge m \neq n] \Rightarrow f_m \neq f_n). \tag{4.627}$$

To do this, we let m and n be arbitrary in $\mathbb{N}$ such that $m \neq n$ holds. Since the standard linear ordering $<$ of $\mathbb{N}$ is connex, the disjunction of $m < n$, $n < m$ and $m = n$ is true. Because $m = n$ is by assumption false, we have that $m < n$ or $n < m$ is true, so that we may apply a proof by cases to establish the desired consequent $f_m \neq f_n$.

In the first case that $m < n$ is true, we see that $m \in n$ holds in view of (4.190). Since the restriction $f \upharpoonright n$ has the domain n according to Proposition 3.164, it follows from $m \in n$ that $m \in \operatorname{dom}(f \upharpoonright n)$ holds. Let us observe now that the assumption $m \in \mathbb{N}$ and the fact that $\mathbb{N}$ is the domain of f imply with the Function Criterion that there exists a unique element k in A with $(m, k) \in f$, which we may also write in function/sequence notation as $f_m = k$. Then, the conjunction of the previously established $m \in n$ and $(m, k) \in f$ implies with the definition of a restriction that $(m, k) \in f \upharpoonright n$ holds, which we may write as $(f \upharpoonright n)_m = k$. Combining the two equations for k, we obtain $f_m = (f \upharpoonright n)_m$. Furthermore, $(m, k) \in f \upharpoonright n$ implies (with the definition of a range) that $k \in \operatorname{ran}(f \upharpoonright n)$ holds, and therefore

$$f_m \in \operatorname{ran}(f \upharpoonright n) \tag{4.628}$$

after substitution based on the previously established equation $f_m = k$. Next, let us observe in view of (4.626) that f_n by definition of a minimum) is an element of $A \setminus \operatorname{ran}(f \upharpoonright n)$, so that (by definition of a set difference)

$$f_n \notin \operatorname{ran}(f \upharpoonright n) \tag{4.629}$$

is true in particular. Then, the conjunction of (4.628) and (4.629) implies the desired inequality $f_m \neq f_n$ with (2.4).

In the other case that $n < m$ is true, we may proceed by applying the same chain of arguments as in the first case. Thus, $n < m$ implies $n \in m$, and therefore $n \in \mathrm{dom}(f \upharpoonright m)$. Let us also note that the assumption $n \in \mathbb{N}$ $(= \mathrm{dom}(f))$ gives $n \in \mathrm{dom}(f)$. Thus, there exists a unique k with $(n, k) \in f$, so that $f_n = k$. Then, the conjunction of $n \in m$ and $(n, k) \in f$ implies $(n, k) \in f \upharpoonright m$, so that also $(f \upharpoonright m)_n = k$. The previous two equations for k may be combined to $f_n = (f \upharpoonright m)_n$. In addition, $(n, k) \in f \upharpoonright m$ implies the truth of $k \in \mathrm{ran}(f \upharpoonright m)$, and therefore also of

$$f_n \in \mathrm{ran}(f \upharpoonright m). \tag{4.630}$$

Now, as f_m is defined as the minimum of the set $A \setminus \mathrm{ran}(f \upharpoonright m)$, it is an element of that set difference, so that

$$f_m \notin \mathrm{ran}(f \upharpoonright m) \tag{4.631}$$

holds in particular. Then, the conjunction of (4.630) and (4.631) implies the inequality $f_n \neq f_m$, so that $f_m \neq f_n$ is true in any case. As m and n are arbitrary, we therefore conclude that the universal sentence (4.627) holds, which shows that f is an injection.

Concerning d), we now verify that the sequence $(f_n)_{n \in \mathbb{N}}$ is strictly increasing, by proving

$$\forall n\, (n \in \mathbb{N} \Rightarrow f_n < f_{n^+}) \tag{4.632}$$

according to the Monotony Criterion for strictly increasing sequences. To do this, we let n be arbitrary in $\mathbb{N}$ and recall that $n \in \mathbb{N}$ implies $n \subseteq n^+$ with (2.306). This inclusion further implies

$$f \upharpoonright n \subseteq f \upharpoonright n^+$$

with (3.89). This in turn implies

$$\mathrm{ran}(f \upharpoonright n) \subseteq \mathrm{ran}(f \upharpoonright n^+)$$

with (3.113), and then with (2.122) also

$$A \setminus \mathrm{ran}(f \upharpoonright n) \subseteq A \setminus \mathrm{ran}(f \upharpoonright n^+). \tag{4.633}$$

By definition of a minimum, the terms $f_n = \min[A \setminus \mathrm{ran}(f \upharpoonright n)]$ and $f_{n^+} = \min[A \setminus \mathrm{ran}(f \upharpoonright n^+)]$ defined in (4.626) are lower bounds contained in the corresponding set differences. In view of Exercise 3.46a), these lower bounds are infima, which thus exist. We may therefore apply Exercise 3.331 to infer from (4.633) the inequality

$$\inf[A \setminus \mathrm{ran}(f \restriction n)] \leq \inf[A \setminus \mathrm{ran}(f \restriction n^+)],$$

where the infima are minima (as noted previously). Consequently, we have the inequality

$$\min[A \setminus \mathrm{ran}(f \restriction n)] \leq \min[A \setminus \mathrm{ran}(f \restriction n^+)],$$

which gives $f_n \leq f_{n^+}$ after substitution based on (4.626). This inequality means that $f_n < f_{n^+}$ or $f_n = f_{n^+}$ is true. Now, the fact that $n, n^+ \in \mathbb{N}$ and $n \neq n^+$ (see Corollary 4.9) are both true implies $f_n \neq f_{n^+}$ with (4.627), so that $f_n = f_{n^+}$ is false. Therefore, the first part $f_n < f_{n^+}$ of the preceding disjunction is true. As n is arbitrary, we therefore conclude that (4.632) holds, so that the sequence $(f_n)_{n \in \mathbb{N}}$ is strictly increasing.

Concerning e), we apply a proof by mathematical induction. Regarding the base case ($n = 0$), we recall from b) that $\mathbb{N}$ is a codomain of f, so that f_0 is evidently a natural number, which fact implies $0 \leq f_0$ with (4.187), as desired. Regarding the induction step, we let n be arbitrary in $\mathbb{N}$, make the induction assumption $n \leq f_n$, and show that this implies $n^+ \leq f_{n^+}$. As f is strictly increasing, $f_n < f_{n^+}$ is true. Then, the conjunction of this and the induction assumption implies $n < f_{n^+}$ with the Transitivity Formula for $<$ and $\leq$, which inequality in turn implies the desired $n^+ \leq f_{n^+}$ with (4.157). Since n was arbitrary, we may therefore conclude that the induction also holds, which completes the proof of e) via mathematical induction.

Concerning f), we recall that f is a function with codomain A and prove the surjectivity condition $\mathrm{ran}(f) = A$ by contradiction, assuming that $\mathrm{ran}(f) \neq A$ holds. By definition of a codomain, we have $\mathrm{ran}(f) \subseteq A$, so that $\mathrm{ran}(f) \subset A$ or $\mathrm{ran}(f) = A$ is true according to (2.26). Since $\mathrm{ran}(f) = A$ is false by assumption, the first part $\mathrm{ran}(f) \subset A$ of the preceding disjunction is true. This proper inclusion implies $A \setminus \mathrm{ran}(f) \neq \emptyset$ with (2.127). Let us now observe that the inclusions

$$A \setminus \mathrm{ran}(f) \subseteq A \subseteq \mathbb{N} \tag{4.634}$$

hold with (2.125) and the initial assumption, so that the transitivity of $\subseteq$ yields $(\emptyset \neq)\ A \setminus \mathrm{ran}(f) \subseteq \mathbb{N}$. It then follows with the well-ordering of $\mathbb{N}$ that the minimum

$$m = \min A \setminus \mathrm{ran}(f) \tag{4.635}$$

exists. We now prove by contradiction the sentence

$$m \in \mathrm{ran}(f \restriction m^+), \tag{4.636}$$

assuming its negation

$$m \notin \operatorname{ran}(f \restriction m^+) \tag{4.637}$$

to be true. By definition of a minimum, we have due to (4.635) that m is an element of $A \setminus \operatorname{ran}(f)$, which implies in particular $m \in A$ (by definition of a set difference). The conjunction of this and (4.637) implies (again with the definition of a set difference)

$$m \in A \setminus \operatorname{ran}(f \restriction m^+). \tag{4.638}$$

Because of (4.626), we also have

$$f_{m^+} = \min\,[A \setminus \operatorname{ran}(f \restriction m^+)], \tag{4.639}$$

so that f_{m^+} is by definition of a minimum a lower bound for the set $A \setminus \operatorname{ran}(f \restriction m^+)$. Then, by definition of a lower bound, (4.638) implies $f_{m^+} \leq m$. Together with the fact that $f_m < f_{m^+}$ holds according d), these inequalities imply $f_m < m$ with the Transitivity Formula for $<$ and $\leq$, and therefore $\neg m \leq f_m$ with the Negation Formula for $\leq$. Since $m \leq f_m$ is also true because of e), we obtained a contradiction according to (1.11), which finding completes the proof of (4.636). It then follows with the definition of a range that there exists an element, say $\bar{k}$, such that $(\bar{k}, m) \in f \restriction m^+$ holds. By definition of a restriction, this implies in particular $(\bar{k}, m) \in f$, so that $m \in \operatorname{ran}(f)$ holds (again by definition of a range). As noted earlier, it is true that $m \in A \setminus \operatorname{ran}(f)$, which implies (by definition of a set difference) in particular that $m \notin \operatorname{ran}(f)$ holds. We thus showed that $m \in \operatorname{ran}(f)$ and $m \notin \operatorname{ran}(f)$ are both true, so that we evidently obtained a contradiction, which completes the proof of $\operatorname{ran}(f) = A$ by contradiction. Thus, the function $f : \mathbb{N} \to A$ is a surjection.

Concerning g), we notice that f is a bijection from $\mathbb{N}$ to A since f is both an injection and a surjection, according to c) and f). Because of d), f is therefore a strictly increasing bijective sequence in A. Furthermore, Since $(\mathbb{N}, <)$ is a linearly ordered set, it follows with Theorem 3.76 that the subset A of $\mathbb{N}$ is also linearly ordered (with respect to a unique subset $<_A$ of $<$). Thus, f is a strict ranking of A, by definition.

Since A was arbitrary in the proofs of a) – g), it follows that the lemma is true. □

Proposition 4.132. *The following equations hold for any infinite subset A of $\mathbb{N}$ and for the function f in (4.618).*

$$f_0 = \min A, \tag{4.640}$$

$$f_1 = \min[A \setminus \{\min A\}], \tag{4.641}$$

$$f_2 = \min[A \setminus \{\min A, \min[A \setminus \{\min A\}]\}]. \tag{4.642}$$

Proof. Letting A be an arbitrary set such that A is infinite and a subset of $\mathbb{N}$, we obtain the equations

$$\begin{aligned} f_0 &= \min[A \setminus \mathrm{ran}(f \restriction 0)] \\ &= \min[A \setminus \mathrm{ran}(f \restriction \emptyset)] \\ &= \min[A \setminus \mathrm{ran}(\emptyset)] \\ &= \min[A \setminus \emptyset] \\ &= \min A \end{aligned}$$

with (4.618), (2.49), (3.85), (3.121) and (2.102). Next, we observe the truth of the equations

$$\begin{aligned} f_1 &= \min[A \setminus \mathrm{ran}(f \restriction 1)] \\ &= \min[A \setminus \mathrm{ran}(f \restriction \{0\})] \\ &= \min[A \setminus \{f_0\}] \\ &= \min[A \setminus \{\min A\}] \end{aligned}$$

in light of (4.618), (2.154), (3.642) based on the facts $f \in A^{\mathbb{N}}$ and $0 \in \mathbb{N}$, and (4.640). Finally, we obtain

$$\begin{aligned} f_2 &= \min[A \setminus \mathrm{ran}(f \restriction 2)] \\ &= \min[A \setminus \mathrm{ran}(f \restriction \{0, 1\})] \\ &= \min[A \setminus \{f_0, f_1\}] \\ &= \min[A \setminus \{\min A, \min[A \setminus \{\min A\}]\}] \end{aligned}$$

by applying (4.618), (2.156), (3.576) based on the facts $f \in A^{\mathbb{N}}$ and $0, 1 \in \mathbb{N}$, and (4.641). Since A was arbitrary, we may therefore conclude that the proposition holds. □

Proposition 4.133. *For any natural number n it is true that there is no injection from the set of positive natural numbers to the initial segment of $\mathbb{N}_+$ up to n, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \neg \exists f\,(f : \mathbb{N}_+ \hookrightarrow \{1, \ldots, n\})). \tag{4.643}$$

Proof. We let n be arbitrary and prove the implication by contradiction, assuming that $n \in \mathbb{N}$ holds and assuming that there exists an injection from $\mathbb{N}_+$ to $\{1, \ldots, n\}$, say $\bar{f}$. Let us now observe that $n \in \mathbb{N}$ implies $n^+ \in \mathbb{N}$ with (2.302) and then also $n^+ \in \mathbb{N}_+$ with (2.308), so that $\{1, \ldots, n^+\}$ is a subset of $\mathbb{N}_+$ by definition of an initial segment of $\mathbb{N}_+$. In light of Proposition 3.187, we then see that the restriction of $\bar{f} : \mathbb{N}_+ \hookrightarrow \{1, \ldots, n\}$ to the subset

$\{1,\ldots,n^+\}$ of $\mathbb{N}_+$ is an injection with domain $\{1,\ldots,n^+\}$ and codomain $\{1,\ldots,n\}$. Thus, the existential sentence

$$\exists f\,(f:\{1,\ldots,n^+\}\hookrightarrow\{1,\ldots,n\}) \tag{4.644}$$

holds. Besides $n, n^+ \in \mathbb{N}$, the inequality $n < n^+$ is also true according to (4.153), and therefore Dirichlet's Drawer Principle implies that the negation of (4.644) is true as well, so that we evidently obtained a contradiction. This finding completes the proof of the implication in (4.643) via contradiction, and as n was arbitrary, we may therefore conclude that the proposition holds, as claimed. □

Exercise 4.45. Show for any natural number n that there is no injection from the set of natural numbers to the initial segment of $\mathbb{N}_+$ up to n, i.e.

$$\forall n\,(n\in\mathbb{N}\Rightarrow\neg\exists f\,(f:\mathbb{N}\hookrightarrow\{1,\ldots,n\})). \tag{4.645}$$

(Hint: Proceed in analogy to the proof of Proposition 4.133, observing that $\{1,\ldots,n^+\}$ is also a subset of $\mathbb{N}$.)

Proposition 4.134. *The set* $\mathbb{N}_+$ *is infinite.*

Proof. We prove the proposed sentence by contradiction, assuming $\mathbb{N}_+$ to be not infinite, so that $\mathbb{N}_+$ follows to be finite with the Double Negation Law. Thus, there exist a natural number, say $\bar{n}$, and a bijection from $\{1,\ldots,\bar{n}\}$ to $\mathbb{N}_+$, say $\bar{c}$. It then follows with Theorem 3.212 that the inverse function $\bar{c}^{-1}$ is a bijection from $\mathbb{N}_+$ to $\{1,\ldots,\bar{n}\}$, so that $\bar{c}^{-1}$ is especially an injection from $\mathbb{N}_+$ to $\{1,\ldots,\bar{n}\}$. Thus, the existential sentence

$$\exists f\,(f:\mathbb{N}_+\hookrightarrow\{1,\ldots,\bar{n}\}) \tag{4.646}$$

is true. Since $\bar{n}\in\mathbb{N}$ implies the negation of (4.646) with (4.643), we evidently have a contradiction, so that the proof of the proposed sentence is complete. □

Exercise 4.46. Prove that the set $\mathbb{N}$ is infinite.

(Hint: Proceed in analogy to the proof of Proposition 4.134, using Exercise 4.45.)

Theorem 4.135 (Characterization of infinite sets). *The following sentences are true.*

a) A set A is infinite if there exists a bijection from $\mathbb{N}_+$ to A, that is,

$$\forall A\,(\exists f\,(f:\mathbb{N}_+\rightleftarrows A)\Rightarrow A\text{ is infinite}). \tag{4.647}$$

b) A set A is infinite if there exists a bijection from $\mathbb{N}$ to A, that is,

$$\forall A\,(\exists f\,(f : \mathbb{N} \rightleftarrows A) \Rightarrow A \text{ is infinite}). \tag{4.648}$$

Proof. Concerning a), we let A be arbitrary and prove the implication by contradiction, assuming that there exists a bijection from $\mathbb{N}_+$ to A, say

$$\bar{f} : \mathbb{N}_+ \rightleftarrows A,$$

and assuming moreover that A is a finite set, so that there exist a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to A, say

$$\bar{c} : \{1, \ldots, \bar{n}\} \rightleftarrows A.$$

Then, the inverse function $\bar{c}^{-1}$ is a bijection from A to $\{1, \ldots, \bar{n}\}$ due to Theorem 3.212, i.e.

$$\bar{c}^{-1} : A \rightleftarrows \{1, \ldots, \bar{n}\}.$$

Consequently, the composition $\bar{c}^{-1} \circ \bar{f}$ is a bijection from $\mathbb{N}_+$ to $\{1, \ldots, \bar{n}\}$ in view of Theorem 3.207, so that $\bar{c}^{-1} \circ \bar{f}$ is in particular an injection. Thus, the existential sentence

$$\exists f\,(f : \mathbb{N}_+ \hookrightarrow \{1, \ldots, \bar{n}\})$$

is true. Since $\bar{n} \in \mathbb{N}$ implies with (4.643) the negation of the preceding existential sentence, we have a contradiction, which proves the implications in (4.648). Since A was arbitrary, we may therefore conclude that a) holds. □

Exercise 4.47. Establish Part b) of Theorem 4.135.

(Hint: Proceed in analogy to the proof of a), applying now (4.645).)

We now extend the concept of counting a finite set (which ends by producing a natural number n) to the unending counting of an infinite set.

Definition 4.16 (Infinite denumeration). For any set A we say that a set d is an *infinite denumeration* of A iff d is a bijection from the set of natural numbers to A, i.e. iff

$$d : \mathbb{N} \rightleftarrows A. \tag{4.649}$$

Note 4.24. If, for a given set A, we have a function c satisfying (4.649), then A and thus the range of d is infinite because of the Characterization of infinite sets; it is therefore indeed justified to speak of an 'infinite' denumeration.

4.7.3. Countable sets

Definition 4.17 (Countable set, countably infinite set). We say that a set A is *countable* iff

(1) there exists a denumeration of A of length n for some $n \in \mathbb{N}$, i.e.

$$\exists n, c\,(n \in \mathbb{N} \wedge c : \{1, \ldots, n\} \rightleftarrows A), \tag{4.650}$$

(i.e. A is a finite set) or

(2) there exists an infinite denumeration of A, i.e.

$$\exists d\,(d : \mathbb{N} \rightleftarrows A), \tag{4.651}$$

in which case we call A a *countably infinite set*.

Furthermore, we say that a set A is *uncountable* iff A is not countable, i.e. iff the negation of the disjunction of (1) and (2) holds.

Corollary 4.136. *A set A is uncountable iff A is infinite and there is no bijection from $\mathbb{N}$ to A.*

Proof. We let A be an arbitrary set. In view of De Morgan's Law (1.52) we see that A is uncountable iff the conjunction of the negations of (1) and (2) holds. Here, the negation of (1) means that A is infinite. □

Exercise 4.48. Show for any countable set A that either (4.650) or (4.651) holds, i.e. that (4.650) and (4.651) are not simultaneously true.

(Hint: Apply Method 1.12 to prove that the negation of the conjunction of (4.650) and (4.651) is true, and apply similar arguments as in the proof of (4.647).)

The set of natural numbers can be counted (without end).

Corollary 4.137. *The set $\mathbb{N}$ is countably infinite.*

Proof. The identity function on $\mathbb{N}$ is a bijection from $\mathbb{N}$ to $\mathbb{N}$ according to Corollary 3.203. Thus, the set $\mathbb{N}$ satisfies (4.651). □

Countability either of a finite or an infinite set A can now be verified by associating its elements with distinct elements of $\mathbb{N}$, either by means of an injection from the considered set A to the counting set $\mathbb{N}$ or via a surjection from the counting set $\mathbb{N}$ to A. The resulting criteria (which we state as the following theorem) may be viewed as generalizations of the previously established Finiteness Criteria.

Theorem 4.138 (Countability Criteria). *The following sentences are true.*

a) A set A is countable iff there exists an injection from A to the set of natural numbers, that is,

$$\forall A\,(A \text{ is countable } \Leftrightarrow \exists f\,(f : A \hookrightarrow \mathbb{N})). \tag{4.652}$$

b) A set A is countable iff A is empty or there exists a surjection from the set of natural numbers to A, that is,

$$\forall A\,(A \text{ is countable } \Leftrightarrow [A = \emptyset \vee \exists f\,(f : \mathbb{N} \twoheadrightarrow A)]). \tag{4.653}$$

Proof. Concerning a), we let A be an arbitrary set. To prove the first part ('$\Rightarrow$') of the stated equivalence, we assume that A is countable, which means that there (either) exists a denumeration $c : \{1, \ldots, n\} \rightleftarrows A$ for some $n \in \mathbb{N}$ or an infinite denumeration $c : \mathbb{N} \rightleftarrows A$ of A. We now use this disjunction to prove the desired consequent by cases.

In the first case, there is a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to A, say

$$\bar{c} : \{1, \ldots, \bar{n}\} \rightleftarrows A.$$

Then, we obtain the bijective inverse function

$$\bar{c}^{-1} : A \rightleftarrows \{1, \ldots, \bar{n}\}$$

with Theorem 3.212, which is especially an injection, that is,

$$\bar{c}^{-1} : A \hookrightarrow \{1, \ldots, \bar{n}\}.$$

Observing that $\bar{n} \in \mathbb{N}$ implies $\{1, \ldots, \bar{n}\} \subseteq \mathbb{N}$ with (4.240), we may now apply Exercise 3.78 to obtain the injection

$$\bar{c}^{-1} : A \hookrightarrow \mathbb{N},$$

so that the existential sentence in (4.652) holds for the first case.

In the second case, there is a bijection from $\mathbb{N}$ to A, say

$$\bar{d} : \mathbb{N} \rightleftarrows A,$$

which gives the bijection

$$\bar{d}^{-1} : A \rightleftarrows \mathbb{N}$$

(again with Theorem 3.212); this bijection is in particular an injection, i.e.

$$\bar{d}^{-1} : A \hookrightarrow \mathbb{N},$$

which shows that the existential sentence in (4.652) holds in any case. Thus, the the proof of the first part of the equivalence in (4.652) is complete.

To prove the second part ('$\Leftarrow$') of the proposed equivalence, we assume that there exists an injection from A to $\mathbb{N}$, say

$$\bar{f} : A \hookrightarrow \mathbb{N}.$$

We then obtain in view of (3.664) the bijection

$$\bar{f} : A \rightleftarrows \mathrm{ran}(\bar{f}),$$

so that the inverse function is (again in view of Theorem 3.212) the bijection

$$\bar{f}^{-1} : \mathrm{ran}(\bar{f}) \rightleftarrows A$$

Here, the Law of the Excluded Middle shows that the range $\mathrm{ran}(\bar{f})$ is a finite set or an infinite set. We may therefore carry out a proof by cases based on this disjunction.

On the one hand, if $\mathrm{ran}(\bar{f}$ is finite, then there is a particular natural number $\bar{m}$ and a particular bijection

$$\bar{\bar{c}} : \{1, \ldots, \bar{m}\} \rightleftarrows \mathrm{ran}(\bar{f}).$$

Consequently, we see in light of Theorem 3.207 that the composition of $\bar{f}^{-1}$ and $\bar{\bar{c}}$ is the bijection

$$\bar{f}^{-1} \circ \bar{\bar{c}} : \{1, \ldots, \bar{m}\} \rightleftarrows A.$$

This finding proves the existence of a denumeration of A of length n for some $n \in \mathbb{N}$, so that A is finite and therefore countable.

On the other hand, if $\mathrm{ran}(\bar{f}$ is infinite, then $\mathrm{ran}(\bar{f}$ is an infinite subset of $\mathbb{N}$, because this range is included in the codomain $\mathbb{N}$ of $\bar{f}$. It follows from this with Lemma 4.131 that there exists the (bijective) strict ranking of A

$$\bar{\bar{d}} : \mathbb{N} \rightleftarrows A,$$

so that we obtain the bijection

$$\bar{f}^{-1} \circ \bar{\bar{d}} : \mathbb{N} \rightleftarrows A$$

(using again Theorem 3.207). Thus, there exists an infinite denumeration of A, so that A is countable also in the second case. This completes the proof of the second part of the equivalence in (4.652).

Since A was initially arbitrary, we may therefore conclude that a) is true.

Concerning b), we let A be an arbitrary set, and we assume first that A is countable. Consequently, there exists in view of the Countability Criterion (4.652) an injection from A to $\mathbb{N}$, say

$$\bar{f} : A \hookrightarrow \mathbb{N}. \tag{4.654}$$

Observing now that the disjunction $A = \emptyset \lor A \neq \emptyset$ is true according to the Law of the Excluded Middle, we may now prove the disjunction in (4.653) by cases. In case of $A = \emptyset$, that disjunction is clearly true. The other case $A \neq \emptyset$ implies with (2.42) that there exists an element in A, say $\bar{a}$. Thus, the conjunction of (4.654) and $\bar{a} \in A$ is true, which implies with (3.692) that the union

$$\bar{f}^{-1} \cup [(\mathbb{N} \setminus \mathrm{ran}(\bar{f})) \times \{\bar{a}\}]$$

is a surjection from $\mathbb{N}$ to A. This proves $\exists f\,(\mathbb{N} \twoheadrightarrow A)$, and the disjunction in (4.653) is then also true. Thus, the proof of the first part ('$\Rightarrow$') of the equivalence in (4.653) is complete.

To prove the second part ('$\Leftarrow$'), we now assume the disjunction in (4.653) to be true, and we prove by cases that A is countable. On the one hand, if $A = \emptyset$ holds, then A is by definition a finite set and therefore countable. On the other hand, if there exists a surjection from $\mathbb{N}$ to A, say $\bar{f} : \mathbb{N} \twoheadrightarrow A$, then it follows with (3.700) that there exists an injection from A to $\mathbb{N}$, so that A follows to be countable with the Countability Criterion (4.652). Thus, the desired consequent holds in any case, so that the proof of the equivalence in (4.653) is complete. Since A was arbitrary, we may therefore conclude that b) is true. □

Corollary 4.139. *Any subset of any countable set is countable, that is,*

$$\forall A\,(A \text{ is countable} \Rightarrow \forall B\,(B \subseteq A \Rightarrow B \text{ is countable})). \tag{4.655}$$

Proof. Letting A be an arbitrary set and assuming A to be countable, it follows with the Countability Criterion (4.652) that there exists an injection from A to $\mathbb{N}$, say

$$\bar{f} : A \hookrightarrow \mathbb{N}.$$

Letting now B be an arbitrary set such that $B \subseteq A$ holds, it follows with Proposition 3.187 that the restriction $\bar{f} \upharpoonright B$ is an injection from B to $\mathbb{N}$, that is,

$$\bar{f} \upharpoonright B : B \hookrightarrow \mathbb{N}.$$

Thus, there exists an injection from B to $\mathbb{N}$, so that B follows to be countable with the Countability Criterion (4.652). Since A and B were arbitrary, we may therefore conclude that the corollary is true. □

Corollary 4.140. *It is true that the difference of any countable set B and any set A constitutes a countable set, that is,*

$$\forall A, B\,(B \text{ is countable} \Rightarrow\; B \setminus A \text{ is countable}). \tag{4.656}$$

Proof. We take arbitrary sets A and B such that B is countable and observe the truth of the inclusion $B \setminus A \subseteq B$ in light of (2.125), so that $B \setminus A$ follows to be countable with (4.655). Here, A and B are arbitrary, so that (4.656) holds indeed. □

Proposition 4.141. *It is true that the range of any function is countable if its domain is countable.*

Proof. Letting X and g be arbitrary sets such that g is a function with countable domain X, we prove the countability of $\operatorname{ran}(g)$ by cases, based on the true disjunction $X = \emptyset \vee X \neq \emptyset$. In the first case $X = \emptyset$, the domain of g is empty, so that the range of g is also empty because of (3.119). Then, the disjunction

$$\operatorname{ran}(g) = \emptyset \,\vee\, \exists f\,(f : \mathbb{N} \twoheadrightarrow \operatorname{ran}(g)) \tag{4.657}$$

is true as well, and this disjunction implies with the Countability Criterion (4.653) that $\operatorname{ran}(g)$ is countable.

In the second case $X \neq \emptyset$, it follows from the countability of X with the preceding Countability Criterion that there exists a set, say $\bar{f}$, such that $\bar{f} : \mathbb{N} \twoheadrightarrow X$. Noting that the given function g is a surjection from X to its range, i.e. $g : X \twoheadrightarrow \operatorname{ran}(g)$, we obtain the surjective composition $g \circ \bar{f} : \mathbb{N} \twoheadrightarrow \operatorname{ran}(g)$ with (3.649). We thus proved the existence of a surjection f from $\mathbb{N}$ to $\operatorname{ran}(g)$, so that the disjunction (4.657) is true again. Therefore, $\operatorname{ran}(g)$ is a countable set also in the second case.

Having completed the proof by cases, we may now infer from this the truth of the proposed universal sentence, because the sets X and g were initially arbitrary. □

Definition 4.18 (Equinumerous/equivalent infinite sets). We say that two infinite sets A and B are *equinumerous* or *equivalent* iff there exists a one-to-one correspondence between them, that is, iff

$$\exists f\,(f : A \rightleftarrows B). \tag{4.658}$$

Notation 4.8. In view of Proposition 4.107 and the previous definition, we may say that any two finite or infinite sets A and B are equinumerous iff there exists a bijection $f : A \rightleftarrows B$. We then also write

$$A \sim B. \tag{4.659}$$

Note 4.25. A set A is then countably infinite iff the set of natural numbers and the set A are equinumerous, i.e. iff

$$\mathbb{N} \sim A. \tag{4.660}$$

The fact that the successor function s^+ of the counting domain $(\mathbb{N}, s^+, 0)$ is a bijection from $\mathbb{N}$ to $\mathbb{N}_+$ according to (4.40) immediately gives the following result.

Corollary 4.142. *The set of natural numbers and the set of positive natural numbers are equinumerous, that is,*

$$\mathbb{N} \sim \mathbb{N}_+. \tag{4.661}$$

Note 4.26. $\mathbb{N}_+$ is countably infinite in view of (4.661) and Note 4.25.

Exercise 4.49. Show that a set A is countable iff

(1) A is equivalent to the initial segment of $\mathbb{N}_+$ up to some $n \in \mathbb{N}$, i.e.

$$\exists n\,(n \in \mathbb{N} \wedge A \sim \{1, \ldots, n\}), \tag{4.662}$$

or

(2) A is equivalent to the set of natural numbers, i.e.

$$A \sim \mathbb{N}. \tag{4.663}$$

(Hint: Apply Method 1.9 to establish both parts of the equivalence, using Theorem 3.212.)

We now justify the notion of *equivalent sets* by establishing a corresponding equivalence relation.

Exercise 4.50. Verify following sentences.

a) Any two identical sets are equinumerous, that is,

$$\forall A\,(A \sim A). \tag{4.664}$$

b) If two sets A and B are equinumerous, then B and A are also equinumerous, i.e.

$$\forall A, B\,(A \sim B \Rightarrow B \sim A). \tag{4.665}$$

c) If two sets A and B as well as B and a set C are equinumerous, then A and C are also equinumerous, that is,

$$\forall A, B, C\,([A \sim B \wedge B \sim C] \Rightarrow A \sim C). \tag{4.666}$$

(Hint: Apply Corollary 3.203, Theorem 3.212, and Theorem 3.207.)

We may apply (4.665) directly to (4.661) to obtain another example of equinumerous sets.

Corollary 4.143. *The set of positive natural numbers and the set of natural numbers are equinumerous, that is,*

$$\mathbb{N}_+ \sim \mathbb{N}. \tag{4.667}$$

Theorem 4.144 (Equivalence relation of equinumerosity). *The following sentences are true for any set system $\mathcal{K}$.*

a) There exists a unique set $R_\sim$ consisting of all the ordered pairs (A, B) such that A and B are equinumerous sets in $\mathcal{K}$, in the sense that

$$\exists! R_\sim \,\forall Z \,(Z \in R_\sim \Leftrightarrow [Z \in \mathcal{K} \times \mathcal{K} \,\wedge\, \exists A, B \,(A \sim B \,\wedge\, (A, B) = Z)]). \tag{4.668}$$

b) The set $R_\sim$ is a binary relation on $\mathcal{K}$ satisfying

$$\forall A, B \,(A, B \in \mathcal{K} \Rightarrow [A \, R_\sim \, B \Leftrightarrow A \sim B]). \tag{4.669}$$

c) Furthermore, the binary relation $R_\sim$ is an equivalence relation on $\mathcal{K}$.

Proof. Letting $\mathcal{K}$ be an arbitrary set system, we may apply the Axiom of Specification and the Equality Criterion for sets to obtain the true uniquely existential sentence (4.668). Thus, the set $R_\sim$ satisfies

$$\forall Z \,(Z \in R_\sim \Leftrightarrow [Z \in \mathcal{K} \times \mathcal{K} \,\wedge\, \exists A, B \,(A \sim B \,\wedge\, (A, B) = Z)]), \tag{4.670}$$

which shows that $Z \in R_\sim$ implies in particular $Z \in \mathcal{K} \times \mathcal{K}$ for any Z, so that the inclusion $R_\sim \subseteq \mathcal{K} \times \mathcal{K}$ follows to be true by definition of a subset. Thus, the set $R_\sim$ is a binary relation on $\mathcal{K}$, and every ordered pair in $R_\sim$ is (by definition of the Cartesian product of two sets) formed by two sets in $\mathcal{K}$.

Next, we establish (4.669), letting $\bar{A}$ and $\bar{B}$ be arbitrary and assuming $\bar{A}, \bar{B} \in \mathcal{K}$ to be true. Regarding the first part ('$\Rightarrow$') of the equivalence, we assume furthermore that $\bar{A} \, R_\sim \, \bar{B}$ holds, and we write this as $(\bar{A}, \bar{B}) \in R_\sim$. This implies with (4.670) in particular that there exist sets, say $\bar{\bar{A}}$ and $\bar{\bar{B}}$, such that the conjunction of $\bar{\bar{A}} \sim \bar{\bar{B}}$ and $(\bar{\bar{A}}, \bar{\bar{B}}) = (\bar{A}, \bar{B})$ holds. The latter equation gives $\bar{\bar{A}} = \bar{A}$ and $\bar{\bar{B}} = \bar{B}$ with the Equality Criterion for ordered pairs, so that $\bar{\bar{A}} \sim \bar{\bar{B}}$ yields $\bar{A} \sim \bar{B}$ via substitution. Thus, the first part of the equivalence in (4.669) holds. Regarding the second part ('$\Leftarrow$'), we now assume $\bar{A} \sim \bar{B}$ to be true, which shows in light of the basic fact $(\bar{A}, \bar{B}) = (\bar{A}, \bar{B})$ that the existential sentence

$$\exists A, B\,(A \sim B \,\wedge\, (A, B) = (\bar{A}, \bar{B})) \tag{4.671}$$

is true. Moreover, since $\bar{A}, \bar{B} \in \mathcal{K}$ means $\bar{A} \in \mathcal{K} \,\wedge\, \bar{B} \in \mathcal{K}$, we obtain with the definition of the Cartesian product of two sets

$$(\bar{A}, \bar{B}) \in \mathcal{K} \times \mathcal{K},$$

which implies together with (4.671) the truth of $(\bar{A}, \bar{B}) \in R_{\sim}$ with (4.670). As we may write this finding as $\bar{A}\, R_{\sim}\, \bar{B}$, the proof of the second part of the equivalence in (4.669) is complete. Since $\bar{A}$ and $\bar{B}$ are arbitrary sets, we may therefore conclude that the universal sentence (4.669) is true.

We now verify that the binary relation $R_{\sim}$ is reflexive, that is,

$$\forall A\,(A \in \mathcal{K} \Rightarrow A\, R_{\sim}\, A). \tag{4.672}$$

Letting $\bar{A}$ be arbitrary and assuming $\bar{A} \in \mathcal{K}$ to be true, it follows with the Idempotent Law for the conjunction that $\bar{A} \in \mathcal{K} \wedge \bar{A} \in \mathcal{K}$ also holds, which yields $\bar{A}, \bar{A} \in \mathcal{K}$. Now, since $\bar{A} \sim \bar{A}$ holds according to (4.664), we obtain the desired $\bar{A}\, R_{\sim}\, \bar{A}$ with (4.669). Because $\bar{A}$ is arbitrary, we may therefore conclude that (4.672) holds, which universal sentence shows that the binary relation $R_{\sim}$ on $\mathcal{K}$ is reflexive.

Next, we show that $R_{\sim}$ is symmetric and verify for this purpose

$$\forall A, B\,(A, B \in \mathcal{K} \Rightarrow [A\, R_{\sim}\, B \Rightarrow B\, R_{\sim}\, A]). \tag{4.673}$$

We take two arbitrary elements $\bar{A}, \bar{B} \in \mathcal{K}$ and assume $\bar{A}\, R_{\sim}\, \bar{B}$. This assumption yields $\bar{A} \sim \bar{B}$ in view of (4.669), and this further implies $\bar{B} \sim \bar{A}$ with (4.665), which in turn gives $\bar{B}\, R_{\sim}\, \bar{A}$ by applying (4.669) again. Since $\bar{A}$ and $\bar{B}$ were arbitrary, we may therefore conclude that (4.673) is true, which means that $R_{\sim}$ is a symmetric binary relation on $\mathcal{K}$.

Finally, we establish the transitivity of $R_{\sim}$ by verifying

$$\forall A, B, C\,(A, B, C \in \mathcal{K} \Rightarrow [(A\, R_{\sim}\, B \,\wedge\, B\, R_{\sim}\, C) \Rightarrow A\, R_{\sim}\, C]). \tag{4.674}$$

Letting $\bar{A}, \bar{B}, \bar{C} \in \mathcal{K}$ be arbitrary and assuming $\bar{A}\, R_{\sim}\, \bar{B}$ as well as $\bar{B}\, R_{\sim}\, \bar{C}$ to be true, we then obtain $\bar{A} \sim \bar{B}$ and $\bar{B} \sim \bar{C}$ with (4.669). These two findings in turn imply $\bar{A} \sim \bar{C}$ with (4.666), which then evidently further implies $\bar{A}\, R_{\sim}\, \bar{C}$, as desired. Since $\bar{A}, \bar{B}, \bar{C}$ are arbitrary, we may infer from this the truth of (4.674).

This completes the proof that the binary relation $R_{\sim}$ on $\mathcal{K}$ is reflexive, symmetric and transitive, so that $R_{\sim}$ constitutes an equivalence class. $\square$

Proposition 4.145. *If two sets A and B as well as two sets C and D are equinumerous, then the Cartesian products $A \times C$ and $B \times D$ are also equinumerous, that is,*

$$\forall A, B, C, D\,([A \sim B \wedge C \sim D] \Rightarrow A \times C \sim B \times D). \tag{4.675}$$

Proof. We let A, B, C and D be arbitrary sets and assume $A \sim B$ as well as $C \sim D$, so that there exist a bijection from A to B and a bijection from C to D, say $f_1 : A \rightleftarrows B$ and $f_2 : C \rightleftarrows D$, according to Notation 4.8. Let us now apply the Axiom of Specification in connection with the Equality Criterion for sets to establish the unique existence of a set F which satisfies

$$\begin{aligned}&\forall z\,(z \in F \Leftrightarrow [z \in (A \times C) \times (B \times D)\\ &\quad \wedge\ \exists a, c\,(a \in A \wedge c \in C \wedge z = ((a,c),(f_1(a), f_2(c))))]).\end{aligned} \tag{4.676}$$

Since $z \in F$ implies evidently in particular $z \in (A \times C) \times (B \times D)$ for any z, it follows with the definition of a subset that $F \subseteq (A \times C) \times (B \times D)$ holds, so that we may view F as a binary relation $F \subseteq X \times Y$ with $X = A \times C$ and $Y = B \times D$. Next, we apply the Function Criterion to prove that F is a function with domain $X = A \times C$ and codomain $Y = B \times D$. For this purpose, we verify

$$\forall x\,(x \in A \times C \Rightarrow \exists! y\,(y \in B \times D \wedge (x, y) \in F)). \tag{4.677}$$

Letting x be arbitrary and assuming $\bar{x} \in A \times C$ to be true, it follows by definition of the Cartesian product of two sets that there is an element in A, say $\bar{a}$, and an element in C, say $\bar{c}$, with $(\bar{a}, \bar{c}) = \bar{x}$. Therefore, the function values $f_1(\bar{a})$ and $f_2(\bar{c})$ are uniquely specified elements of B and D, respectively, according to the Function Criterion. Consequently, we may define first the ordered pair $\bar{y} = (f_1(\bar{a}), f_2(\bar{c}))$ and then the ordered pair

$$\bar{z} = (\bar{x}, \bar{y}) = ((\bar{a}, \bar{c}), (f_1(\bar{a}), f_2(\bar{c}))),$$

and we see in light of $\bar{a} \in A$ and $\bar{c} \in C$ as well as the preceding equations that $\bar{z}$ satisfies the existential sentence in (4.676). Furthermore, $f_1(\bar{a}) \in B$ and $f_2(\bar{c}) \in D$ imply $[\bar{y} =]\ (f_1(\bar{a}), f_2(\bar{c})) \in B \times D$ by definition of the Cartesian product of two sets. As $[\bar{x} =]\ (\bar{a}, \bar{c}) \in A \times C$ also holds, we obtain then (again by definition of the Cartesian product of two sets)

$$[\bar{z} = (\bar{x}, \bar{y}) =] \quad ((\bar{a}, \bar{c}), (f_1(\bar{a}), f_2(\bar{c}))) \in (A \times C) \times (B \times D).$$

The conjunction of $\bar{z} \in (A \times C) \times (B \times D)$ and the previously established existential sentence (which $\bar{z}$ satisfies) implies now $\bar{z} \in F$ with (4.676).

Thus, $\bar{y} \in B \times D$ and $(\bar{x}, \bar{y}) \in F$ are both true, so that the existential part of the uniquely existential sentence in (4.677) holds.

To establish the uniqueness part, we take arbitrary y and y' such that $y, y' \in B \times D$ and $(\bar{x}, y), (\bar{x}, y') \in F$ are true. It then follows with (4.676) that there constants, say $\bar{a}, \bar{c}$ as well as $\bar{a}', \bar{c}'$ satisfying $\bar{a}, \bar{a}' \in A$ and $\bar{c}, \bar{c}' \in C$ as well as the equations

$$(\bar{x}, y) = ((\bar{a}, \bar{c}), (f_1(\bar{a}), f_2(\bar{c}))),$$
$$(\bar{x}, y') = ((\bar{a}', \bar{c}'), (f_1(\bar{a}'), f_2(\bar{c}'))).$$

These equations imply with the Equality Criterion for ordered pairs $\bar{x} = (\bar{a}, \bar{c})$ and $y = (f_1(\bar{a}), f_2(\bar{c}))$ as well as $\bar{x} = (\bar{a}', \bar{c}')$ and $y' = (f_1(\bar{a}'), f_2(\bar{c}'))$. Combining now the two equations for $\bar{x}$ via substitution yields first $(\bar{a}, \bar{c}) = (\bar{a}', \bar{c}')$, then with the Equality Criterion for ordered pairs $\bar{a} = \bar{a}'$ and $\bar{c} = \bar{c}'$. Next, we apply substitutions based on these two equations to obtain $f_1(\bar{a}') = f_1(\bar{a})$ and $f_2(\bar{c}') = f_2(\bar{c})$, so that the Equality Criterion for ordered pairs gives now

$$[y' =] \quad (f_1(\bar{a}'), f_2(\bar{c}')) = (f_1(\bar{a}), f_2(\bar{c})) \quad [= y].$$

These equations yield $y = y'$, and since y and y' are arbitrary, we may therefore conclude that the uniqueness part of the uniquely existential sentence in (4.677) holds as well. Then, since $\bar{x}$ was also arbitrary, we may further conclude that the universal sentence (4.677) is true. Consequently, F is a function from $A \times C$ to $B \times D$ according to the Function Criterion, so that F is the mapping

$$F : A \times C \to B \times D, \qquad (a, c) \mapsto F((a, c)) = (f_1(a), f_2(c)). \tag{4.678}$$

We now verify that F is a bijection by demonstrating that F is both an injection and a surjection. Concerning injectivity, we take arbitrary x and x', assume $x, x' \in A \times C$ and $F(x) = F(x')$ to be true, and we show that this implies $x = x'$. The former assumption implies (by definition of the Cartesian product of two sets) on the one hand that there exist constants, say $\bar{a}$ and $\bar{c}$, with $\bar{a} \in A$, $\bar{c} \in C$ and $(\bar{a}, \bar{c}) = x$, and on the other hand that there are constants, say $\bar{a}'$ and $\bar{c}'$, with $\bar{a}' \in A$, $\bar{c}' \in C$ and $(\bar{a}', \bar{c}') = x'$. Thus, we may write the latter assumption $F(x) = F(x')$ equivalently as $F((\bar{a}, \bar{c})) = F((\bar{a}', \bar{c}'))$ by applying substitutions, and then also as $(f_1(\bar{a}), f_2(\bar{c})) = (f_1(\bar{a}'), f_2(\bar{c}'))$ according to (4.678). The preceding equation now implies $f_1(\bar{a}) = f_1(\bar{a}')$ and $f_2(\bar{c}) = f_2(\bar{c}')$ with the Equality Criterion for ordered pairs. As the bijections f_1 and f_2 are in particular injections, these equations imply $\bar{a} = \bar{a}'$ as well as $\bar{c} = \bar{c}'$, which further imply (again with the Equality Criterion for ordered pairs)

$$[x =] \quad (\bar{a}, \bar{c}) = (\bar{a}', \bar{c}') \quad [= x'],$$

so that $x = x'$ is indeed true. Since x and x' were arbitrary, we may infer from this finding that F is an injection.

Concerning the surjectivity of $F : A \times C \to B \times D$, we apply the Surjection Criterion and take for this purpose an arbitrary y, assume $y \in B \times D$ to be true, and establish the truth of $F(x) = y$ for some x. Let us first observe that the assumed $y \in B \times D$ implies (by definition of the Cartesian product of two sets) the existence of two particular elements $\bar{b} \in B$ and $\bar{d} \in D$ satisfying $(\bar{b}, \bar{d}) = y$. As the bijections f_1 and f_2 are in particular surjections $f_1 : A \twoheadrightarrow B$ and $f_2 : C \twoheadrightarrow D$, it follows with the Surjection Criterion from $\bar{b} \in B$ and from $\bar{d} \in D$ that there are particular constants $\bar{a}$ and $\bar{c}$ which satisfy $f_1(\bar{a}) = \bar{b}$ and $f_2(\bar{b}) = \bar{d}$. Consequently, the previously established $y = (\bar{b}, \bar{d})$ yields

$$y = (f_1(\bar{a}), f_2(\bar{b})) = F((\bar{a}, \bar{c}))$$

by applying substitutions and by using the equation in (4.678). Thus, $F(x) = y$ holds for some x, and since y was arbitrary, we may therefore conclude that (the injection) $F : A \times C \to B \times D$ is a surjection, according to the Surjection Criterion. This completes the proof that the function F in (4.678) is a bijection. In view of Notation 4.8, $A \times C$ and $B \times D$ are then equivalent sets, as claimed. Since A, B, C and D were initially arbitrary sets, we may now finally conclude that the proposition is true. □

Since $\mathbb{N}_+ \sim \mathbb{N}$ and $\mathbb{N} \sim \mathbb{N}_+$ are true according to (4.667) and (4.661), an application of the Idempotent Law for the conjunction yields in view of the preceding proposition the following set equivalences.

Corollary 4.146. *The Cartesian products* $\mathbb{N}_+ \times \mathbb{N}_+$ *and* $\mathbb{N} \times \mathbb{N}$ *are equinumerous, that is,*

$$\mathbb{N}_+ \times \mathbb{N}_+ \sim \mathbb{N} \times \mathbb{N}, \tag{4.679}$$

$$\mathbb{N} \times \mathbb{N} \sim \mathbb{N}_+ \times \mathbb{N}_+. \tag{4.680}$$

The following proposition is about a relationship between the Cartesian product of a family of sets and the Cartesian product of two sets.

Proposition 4.147. *It is true for any natural number n and for any sequence of sets $A = (A_i \,|\, i \in \{1, \ldots, n+1\})$ that the Cartesian product of the sequence A and the Cartesian product of the restricted sequence $A \restriction \{1, \ldots, n\} = (A_i \,|\, i \in \{1, \ldots, n\})$ and the term A_{n+1} are equinumerous, that is,*

$$\forall n, A\left([n \in \mathbb{N} \wedge A = (A_i \,|\, i \in \{1, \ldots, n+1\})] \Rightarrow \bigtimes_{i=1}^{n+1} A_i \sim \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}\right). \tag{4.681}$$

Proof. We take arbitrary sets n and A such that n is a natural number and such that A is a sequence of sets with index set $\{1,\ldots,n+1\}$. To prove the stated equivalence, we establish a bijection from the Cartesian product $\bigtimes_{i=1}^{n+1} A_i$ to the Cartesian product $\left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}$. To do this, we first verify

$$\forall x\,(x \in \bigtimes_{i=1}^{n+1} A_i \Rightarrow \exists! y\,(y = (x \upharpoonright \{1,\ldots,n\}, x_{n+1}))), \tag{4.682}$$

letting x be arbitrary and assuming $x \in \bigtimes_{i=1}^{n+1} A_i$ to be true. By definition of the Cartesian product of a family of sets, x is then a family with index set $\{1,\ldots,n+1\}$, so that the term x_{n+1} is clearly specified. Moreover, the assumption $n \in \mathbb{N}$ gives rise to the initial segment $\{1,\ldots,n\}$ of $\mathbb{N}_+$. We may therefore define the ordered pair $(x \upharpoonright \{1,\ldots,n\}, x_{n+1})$, which thus constitutes a constant. Consequently, the uniquely existential sentence in (4.682) follows to be true with (1.109). Since x is arbitrary, we may then conclude that the universal sentence (4.682) is true. According to Function definition by replacement, there is now a unique function f with domain $\bigtimes_{i=1}^{n+1} A_i$ such that

$$\forall x\,(x \in \bigtimes_{i=1}^{n+1} A_i \Rightarrow f(x) = (x \upharpoonright \{1,\ldots,n\}, x_{n+1})). \tag{4.683}$$

We can show here that $\left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}$ constitutes the range of the function f, i.e. that the range of the function f is included in the preceding Cartesian product. For this purpose, we demonstrate the truth of

$$\forall y\,(y \in \operatorname{ran}(f) \Leftrightarrow y \in \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}). \tag{4.684}$$

We take an arbitrary constant y and assume first $y \in \operatorname{ran}(f)$ to be true, so that the definition of a range gives us a particular constant $\bar{x}$ such that $(\bar{x}, y) \in f$ holds. Recalling that $\bigtimes_{i=1}^{n+1} A_i$ is the domain of f, we thus have that $\bar{x}$ is an element of that Cartesian product. This means that $\bar{x}$ is a family with index set $\{1,\ldots,n+1\}$ whose terms satisfy

$$\forall i\,(i \in \{1,\ldots,n+1\} \Leftrightarrow \bar{x}_i \in A_i). \tag{4.685}$$

As indicated by Notation 4.6, the restriction $\bar{x} \upharpoonright \{1,\ldots,n\}$ is therefore a family/sequence with index set $\{1,\ldots,n\}$ and terms satisfying

$$\forall i\,(i \in \{1,\ldots,n\} \Leftrightarrow [\bar{x} \upharpoonright \{1,\ldots,n\}]_i \in A_i),$$

so that

$$\bar{x} \restriction \{1, \ldots, n\} \in \bigtimes_{i=1}^{n} A_i \tag{4.686}$$

holds. Since (4.685) shows clearly that $\bar{x}_{n+1} \in A_{n+1}$ is also true, we obtain with (4.686) and the definition of the Cartesian product of two sets

$$(\bar{x} \restriction \{1, \ldots, n\}, \bar{x}_{n+1}) \in \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}. \tag{4.687}$$

Let us observe now that the previously established $(\bar{x}, y) \in f$ can be written in function notation as $y = f(\bar{x})$, and that the previous finding $\bar{x} \in \bigtimes_{i=1}^{n+1} A_i$ implies the truth of $f(\bar{x}) = (\bar{x} \restriction \{1, \ldots, n\}, \bar{x}_{n+1})$ with (4.683). Due to (4.687), substitutions give us then the desired consequent

$$y \in \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1} \tag{4.688}$$

of the first part ('$\Rightarrow$') of the equivalence in (4.684).

To establish the second part ('$\Leftarrow$'), we assume the antecedent (4.688) to be true. By definition of the Cartesian product of two sets, there are then particular elements $\bar{a} \in \bigtimes_{i=1}^{n} A_i$ and $\bar{b} \in A_{n+1}$ with $y = (\bar{a}, \bar{b})$. Thus, $\bar{a}$ is a family with index set $\{1, \ldots, n\}$ and terms satisfying

$$\forall i\, (i \in \{1, \ldots, n\} \Leftrightarrow \bar{a}_i \in A_i). \tag{4.689}$$

As $n+1$ is not an element of $\{1, \ldots, n\}$ in view of (4.250), we can form the function $g = \bar{a} \cup \{(n+1, \bar{b})\}$ by applying Proposition 3.177, whose domain is then given by $\{1, \ldots, n\} \cup \{n+1\} = \{1, \ldots, n+1\}$, recalling (4.241). Thus, g is a family with index set $\{1, \ldots, n+1\}$, and we show now that its terms satisfy

$$\forall i\, (i \in \{1, \ldots, n+1\} \Rightarrow g_i \in A_i). \tag{4.690}$$

Letting i be arbitrary and assuming $i \in \{1, \ldots, n+1\}$ $[= \{1, \ldots, n\} \cup \{n+1\}]$ to be true, we obtain with the definition of the union of two sets the true disjunction $i \in \{1, \ldots, n\} \vee i \in \{n+1\}$, which we use to prove $g_i \in A_i$ by cases. The case $i \in \{1, \ldots, n\}$ implies $\bar{a}_i \in A_i$ with (4.689), where we can write $\bar{a}_i = \bar{a}(i)$ and then also $(i, \bar{a}_i) \in \bar{a}$. Consequently, the ordered pair $(i, \bar{a}_i)$ is also an element of $g = \bar{a} \cup \{(n+1, \bar{b})\}$, by definition of the union of a set system. We can then write this finding $(i, \bar{a}_i) \in g$ in family notation as $\bar{a}_i = g_i$, as desired. The other case $i \in \{n+1\}$ gives us first $i = n+1$ with (2.169) and then $(n+1, \bar{b}) = (i, \bar{b})$ via substitution. This ordered pair is also an element of the union $g = \bar{a} \cup \{(n+1, \bar{b})\}$, that is, $(i, \bar{b}) \in g$, and we can write this in the form $\bar{b} = g_i$. Recalling the truth of $\bar{b} \in A_{n+1}$ and of $i = n+1$, we therefore obtain the desired $g_i \in A_i$ by means of substitutions, completing the proof by cases. Since i was arbitrary, we may infer from the truth of $g_i \in A_i$ the truth of the universal sentence (4.690), which demonstrates that the family g (with index set $\{1, \ldots, n+1\}$) is an element of the Cartesian product $\bigtimes_{i=1}^{n+1} A_i$, and thus of the domain of the function f. The value of f associated with g is then $f(g) = (g \restriction \{1, \ldots, n\}, g_{n+1})$. Within the preceding proof by cases, the first case gave $(i, \bar{a}_i) \in g$ and thus $\bar{a}_i = g_i$ for an arbitrary $i \in \{1, \ldots, n\}$, so that $\bar{a} = g \restriction \{1, \ldots, n\}$ follows to be true according to the Equality Criterion for functions. In addition, the second case gave $\bar{b} = g_{n+1}$, so that we find $f(g) = (\bar{a}, \bar{b})$ $[= y]$ to be true. Writing the resulting equation $y = f(g)$ in the form $(g, y) \in f$, we now see in light of the definition of a range that $y \in \mathrm{ran}(f)$ is true, which completes the proof of the equivalence in (4.684). As y was arbitrary, we can infer from the truth of that equivalence the truth of (4.684), which universal sentence in turn implies with the Equality Criterion for sets

$$\mathrm{ran}(f) = \left[\bigtimes_{i=1}^{n} A_i \right] \times A_{n+1}.$$

We thus proved that the function

$$f : \bigtimes_{i=1}^{n+1} A_i \to \left[\bigtimes_{i=1}^{n} A_i \right] \times A_{n+1} \tag{4.691}$$

constitutes a surjection.

Finally, we show that this surjection is also an injection, i.e. that f satisfies

$$\forall x, x' \left(\left[x, x' \in \bigtimes_{i=1}^{n+1} A_i \wedge f(x) = f(x') \right] \Rightarrow x = x' \right). \tag{4.692}$$

We take arbitrary x and x', assuming $x, x' \in \bigtimes_{i=1}^{n+1} A_i$ and $f(x) = f(x')$ to be both true. By definition of the function f, these two values are given by the ordered pairs

$$f(x) = (x \restriction \{1, \ldots, n\}, x_{n+1})$$
$$f(x') = (x' \restriction \{1, \ldots, n\}, x'_{n+1}),$$

so that their assumed equality can be expressed by

$$(x \restriction \{1, \ldots, n\}, x_{n+1}) = (x' \restriction \{1, \ldots, n\}, x'_{n+1}).$$

Consequently, the Equality Criterion for ordered pairs gives us the two equations

$$x \upharpoonright \{1, \ldots, n\} = x' \upharpoonright \{1, \ldots, n\} \tag{4.693}$$

and

$$x_{n+1} = x'_{n+1}, \tag{4.694}$$

which allow us in the following to prove $x = x'$ via the Equality Criterion for functions (noting that the assumption $x, x' \in \bigtimes_{i=1}^{n+1} A_i$ means that x and x' are both families with common domain $\{1, \ldots, n+1\}$). Thus, the task is to prove the universal sentence

$$\forall i \, (i \in \{1, \ldots, n+1\} \Rightarrow x_i = x'_i). \tag{4.695}$$

Letting $\bar{k}$ be arbitrary and assuming $\bar{k} \in \{1, \ldots, n+1\}$ to be true, we consider once again the two cases $\bar{k} \in \{1, \ldots, n\}$ and $\bar{k} \in \{n+1\}$. In the first case $\bar{k} \in \{1, \ldots, n\}$, we observe first that (4.693) yields with the Equality Criterion for functions

$$\forall i \, (i \in \{1, \ldots, n\} \Rightarrow [x \upharpoonright \{1, \ldots, n\}]_i = [x' \upharpoonright \{1, \ldots, n\}]_i). \tag{4.696}$$

We obtain the true equations

$$x_{\bar{k}} = [x \upharpoonright \{1, \ldots, n\}]_{\bar{k}} = [x' \upharpoonright \{1, \ldots, n\}]_{\bar{k}} = x'_{\bar{k}}$$

by using (3.567), (4.696), and then again (3.567). The second case $\bar{k} \in \{n+1\}$ yields $\bar{k} = n+1$ with (2.169) and then

$$x_{\bar{k}} = x_{n+1} = x'_{n+1} = x'_{\bar{k}}$$

by applying substitutions based on $\bar{k} = n+1$ and based on (4.694). Thus, we find $x_{\bar{k}} = x'_{\bar{k}}$ to be true in both cases, and since $\bar{k}$ is arbitrary, we may therefore conclude that the universal sentence (4.695) holds. This proves that the functions x and x' are indeed equal, so that the proof of the implication in (4.692) is now also complete. Here, x and x' were arbitrary, so that the universal sentence (4.692) is true. Consequently, the surjection (4.691) is also an injection and therefore a bijection. This finding demonstrates that there exists a bijection from the Cartesian product $\bigtimes_{i=1}^{n+1} A_i$ to the Cartesian $\left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}$, which sets are therefore equinumerous, by definition. Initially, the sets n and A were arbitrary, so that the proposed universal sentence follows finally to be true. □

Theorem 4.148 (Cantor-Schröder-Bernstein theorem). *It is true that any two sets X and Y are equinumerous if there are injections from X to Y and from Y to X, that is,*

$$\forall X, Y \, ([\exists f \, (f : X \hookrightarrow Y) \wedge \exists g \, (g : Y \hookrightarrow X)] \Rightarrow X \sim Y). \tag{4.697}$$

Proof. We take arbitrary sets X and Y, assuming that there are injections from X to Y and from Y to X, say $\bar{f} : X \hookrightarrow Y$ and $\bar{g} : Y \hookrightarrow X$. We obtain then the bijection $\bar{g} : Y \rightleftarrows \mathrm{ran}(\bar{g})$ with (3.664), and moreover the bijection $\bar{g}^{-1} : \mathrm{ran}(\bar{g}) \rightleftarrows Y$ with (3.683).

Next, we apply Function definition by replacement to establish the unique function F with domain $\mathbb{N} \times \mathcal{P}(X)$ such that

$$\forall z \, (z \in \mathbb{N} \times \mathcal{P}(X) \Rightarrow \exists n, U \, (z = (n, U) \, \wedge \, \bar{g}[\bar{f}[U]] = F(z))). \qquad (4.698)$$

To achieve this, we prove the universal sentence

$$\forall z \, (z \in \mathbb{N} \times \mathcal{P}(X) \Rightarrow \exists! Y \, (\exists n, U \, (z = (n, U) \, \wedge \, \bar{g}[\bar{f}[U]] = Y))), \qquad (4.699)$$

letting $\bar{z}$ be arbitrary and assuming $\bar{z} \in \mathbb{N} \times \mathcal{P}(X)$ to be true. By definition of the Cartesian product of two sets, there exist then particular elements $\bar{n} \in \mathbb{N}$ and $\bar{U} \in \mathcal{P}(X)$ with $(\bar{n}, \bar{U}) = \bar{z}$, which findings imply especially $\bar{U} \subseteq X$ with the definition of a power set. Therefore, the image $f[\bar{U}]$ under $\bar{f} : X \hookrightarrow Y$ is defined and constitutes a subset of the codomain Y of f, according to (3.720). Consequently, the image $\bar{Y} = \bar{g}[\bar{f}[\bar{U}]]$ under $\bar{g} : Y \hookrightarrow X$ is also a defined. These findings demonstrate the existence of constants n and U for which $\bar{z} = (n, U)$ and $\bar{g}[\bar{f}[U]] = \bar{Y}$ are both true. Having found the constant $\bar{Y}$ satisfying this existential sentence, we now see that the existential part

$$\exists! Y \, (\exists n, U \, (\bar{z} = (n, U) \, \wedge \, \bar{g}[\bar{f}[U]] = Y))$$

of the uniquely existential sentence to be proven holds (for the given element $\bar{z}$). Concerning the uniqueness part, we prove

$$\begin{aligned} \forall Y, Y' \, ([\exists n, U \, (\bar{z} = (n, U) \, \wedge \, \bar{g}[\bar{f}[U]] = Y) \\ \wedge \, \exists n, U \, (\bar{z} = (n, U) \, \wedge \, \bar{g}[\bar{f}[U]] = Y')] \Rightarrow Y = Y'), \end{aligned} \qquad (4.700)$$

taking arbitrary Y, Y and assuming the antecedent to be true. On the one hand, there exist then constants, say $\bar{n}$ and $\bar{U}$, such that $\bar{z} = (\bar{n}, \bar{U})$ and $\bar{g}[\bar{f}[U]] = Y$ holds. On the other hand, there are constants, say $\bar{n}'$ and $\bar{U}'$, satisfing both $\bar{z} = (\bar{n}', \bar{U}')$ and $\bar{g}[\bar{f}[\bar{U}']] = Y'$. Combining the two equations for $\bar{z}$ yields $(\bar{n}, \bar{U}) = (\bar{n}', \bar{U}')$, which equation in turn implies with the Equality Criterion for ordered pairs especially $\bar{U} = \bar{U}'$. Applying now substitution based on this equation, we obtain

$$Y = \bar{g}[\bar{f}[\bar{U}]] = \bar{g}[\bar{f}[\bar{U}']] = Y',$$

so that the resulting $Y = Y$ proves the implication in (4.700). Since Y and Y' are arbitrary, we may therefore conclude that the universal sentence

(4.700) is true, which completes the proof of the uniqueness part and thus the proof of the uniquely existential sentence in (4.699). Here, $\bar{z}$ was also arbitrary, so that the universal sentence (4.699) follows to be true as well. It then follows from this that there exists indeed a unique function F with domain $\mathbb{N} \times \mathcal{P}(X)$ such that (4.698) holds. Let us verify that its range is included in $\mathcal{P}(X)$, i.e. that F satisfies

$$\forall y\, (y \in \mathrm{ran}(F) \Rightarrow y \in \mathcal{P}(X)). \tag{4.701}$$

We let y be arbitrary and assume $y \in \mathrm{ran}(F)$ to be true, so that the definition of a range gives us a particular constant $\bar{z}$ such that $(\bar{z}, y) \in F$ holds. We therefore obtain $\bar{z} \in \mathbb{N} \times \mathcal{P}(X)$ $[= \mathrm{dom}(F)]$ with the definition of a domain. Due to (4.698), there are then particular constants $\bar{n}$ and $\bar{U}$ satisfying $\bar{z} = (\bar{n}, \bar{U})$ as well as $\bar{g}[\bar{f}[\bar{U}]] = F(\bar{z})$. Since we may write $(\bar{z}, y) \in F$ in function notation in the form $y = F(\bar{z})$, we may carry out substitution to obtain $\bar{g}[\bar{f}[\bar{U}]] = y$. As noted earlier, the image $\bar{f}[\bar{U}]$ is a defined subset of Y, so that the image $y = \bar{g}[\bar{f}[\bar{U}]]$ under $\bar{g} : Y \hookrightarrow X$ is also defined and furthermore a subset of X according to (3.720). The definition of a power set gives us then $y \in \mathcal{P}(X)$, as desired, where y was arbitrary, so that the universal sentence (4.701) follows to be true. As this implies the inclusion $\mathrm{ran}(F) \subseteq \mathcal{P}(X)$ with the definition of a subset, we see that $\mathcal{P}(X)$ is a codomain of F.

Based on this function $F : \mathbb{N} \times \mathcal{P}(X) \to \mathcal{P}(X)$, we may apply now Definition by recursion (for $\mathbb{N}$) to obtain the unique sequence $u : \mathbb{N} \to \mathcal{P}(X)$ with terms

$$(1) \quad u(0) \ = X \setminus \mathrm{ran}(\bar{g}), \tag{4.702}$$

$$(2) \quad u(n^+) = F((n, u(n))) \quad \text{for any } n \in \mathbb{N}, \tag{4.703}$$

noting that the inclusion $X \setminus \mathrm{ran}(\bar{g}) \subseteq X$ holds according to (2.125), so that $X \setminus \mathrm{ran}(\bar{g}) \in \mathcal{P}(X)$ is true by definition of a power set (as required). Thus, we may form the union $\bigcup_{n=0}^{\infty} u_n$ of the sequence u.

In the next step we apply once again Function definition by replacement to establish a new function h with domain X such that

$$\begin{aligned} &\forall x\, (x \in X \\ &\quad \Rightarrow ([x \in \bigcup_{n=0}^{\infty} u_n \Rightarrow h(x) = \bar{f}(x)] \wedge [x \notin \bigcup_{n=0}^{\infty} u_n \Rightarrow h(x) = \bar{g}^{-1}(x)])). \end{aligned} \tag{4.704}$$

To accomplish task, we prove accordingly

$$\forall x\, (x \in X \Rightarrow \exists! y\, ([x \in \bigcup_{n=0}^{\infty} u_n \Rightarrow y = \bar{f}(x)] \wedge [x \notin \bigcup_{n=0}^{\infty} u_n \Rightarrow y = \bar{g}^{-1}(x)])), \tag{4.705}$$

letting $\bar{x}$ be arbitrary and assuming $\bar{x} \in X$ to hold. Here, X is the domain of $\bar{f}$, so that the value $\bar{f}(\bar{x})$ is defined. Let us verify that the value $\bar{g}^{-1}(x)$ of the inverse function $\bar{g}^{-1} : \mathrm{ran}(\bar{g}) \to Y$ is defined under the additional assumption $\bar{x} \notin \bigcup_{n=0}^{\infty} u_n$. According to the Characterization of the union of a family of sets, the preceding negation implies the truth of the negation

$$\neg\exists n\,(n \in \mathbb{N} \wedge \bar{x} \in u_n),$$

which in turn implies with the Negation Law for existential conjunctions

$$\forall n\,(n \in \mathbb{N} \Rightarrow \neg\bar{x} \in u_n).$$

With this, the truth of $0 \in \mathbb{N}$ in (2.297) implies $\neg\bar{x} \in u_0$ [$= u(0)$], so that (4.702) yields $\neg\bar{x} \in X \setminus \mathrm{ran}(\bar{g})$ via substitution. According to the definition of a set difference, this means

$$\neg[\bar{x} \in X \wedge \bar{x} \notin \mathrm{ran}(\bar{g})],$$

so that the disjunction of the negations $\neg\bar{x} \in X$ and $\neg\bar{x} \notin \mathrm{ran}(\bar{g})$ follows to be true with De Morgan's Law for the conjunction. Here, the first part $\neg\bar{x} \in X$ of the disjunction is false in view of the initial assumption $\bar{x} \in X$. Consequently, the second part $\neg\bar{x} \notin \mathrm{ran}(\bar{g})$ must be true, so that $\bar{x} \in \mathrm{ran}(\bar{g})$ follows to be true with the Double Negation Law. Thus, $\bar{x}$ turns out to be indeed an element of the domain of $\bar{g}^{-1}$ if $\bar{x} \notin \bigcup_{n=0}^{\infty} u_n$ holds. We now make use of the fact that the Law of the Excluded Middle yields the true disjunction

$$\bar{x} \in \bigcup_{n=0}^{\infty} u_n \vee \bar{x} \notin \bigcup_{n=0}^{\infty} u_n, \tag{4.706}$$

which we use to prove the existential part by cases. In the first case $\bar{x} \in \bigcup_{n=0}^{\infty} u_n$, replacing the variable y by the constant $\bar{f}(\bar{x})$ gives the true implications

$$\left[\bar{x} \in \bigcup_{n=0}^{\infty} u_n \Rightarrow \bar{f}(\bar{x}) = \bar{f}(\bar{x})\right] \wedge \left[\bar{x} \notin \bigcup_{n=0}^{\infty} u_n \Rightarrow \bar{f}(\bar{x}) = \bar{g}^{-1}(\bar{x})\right],$$

because the antecedent and the consequent of the first implication are both true, and because the antecedent of the second implication is false. In the second case $\bar{x} \notin \bigcup_{n=0}^{\infty} u_n$, we may replace y by $\bar{g}^{-1}(\bar{x})$ to obtain the true implications

$$\left[\bar{x} \in \bigcup_{n=0}^{\infty} u_n \Rightarrow \bar{g}^{-1}(\bar{x}) = \bar{f}(\bar{x})\right] \wedge \left[\bar{x} \notin \bigcup_{n=0}^{\infty} u_n \Rightarrow \bar{g}^{-1}(\bar{x}) = \bar{g}^{-1}(\bar{x})\right],$$

since the antecedent of the first one is false and since the antecedent and the consequent of the second one are both true. Thus, the existential part of the uniquely existential sentence in (4.705) holds in any case. To prove the uniqueness part, we let y and y' be arbitrary, assume that the conjunctions

$$\left[x \in \bigcup_{n=0}^{\infty} u_n \Rightarrow y = \bar{f}(x)\right] \wedge \left[x \notin \bigcup_{n=0}^{\infty} u_n \Rightarrow y = \bar{g}^{-1}(x)\right]$$
$$\left[x \in \bigcup_{n=0}^{\infty} u_n \Rightarrow y' = \bar{f}(x)\right] \wedge \left[x \notin \bigcup_{n=0}^{\infty} u_n \Rightarrow y' = \bar{g}^{-1}(x)\right]$$

hold, and show that $y = y'$ is implied. We establish this equation by means of a proof by cases, based again on the previously established disjunction (4.706). Then, the first case $\bar{x} \in \bigcup_{n=0}^{\infty} u_n$ implies the equations $y = \bar{f}(x)$ and $y' = \bar{f}(x)$, whereas the second case implies the equations $y = \bar{g}^{-1}(x)$ and $y' = \bar{g}^{-1}(x)$, so that substitutions give us the desired equation $y = y'$ in both cases. Since y and y' are arbitrary, we may infer from the truth of this equation the truth of the uniqueness part and therefore the truth of the uniquely existential sentence in (4.705). Because $\bar{x}$ was also arbitrary, we may furthermore conclude that the universal sentence (4.705) is true, with the consequence that there exists a unique function h with domain X and values defined according to (4.704). We may now readily show that Y is a codomain of h, i.e. that the range of h is included in Y. According to the definition of a subset, we may show this by demonstrating the truth of the equivalent universal sentence

$$\forall y\,(y \in \mathrm{ran}(h) \Rightarrow y \in Y). \tag{4.707}$$

We let y be arbitrary and assume $y \in \mathrm{ran}(h)$ to be true, so that there exists – by definition of a range – a constant, say $\bar{\bar{x}}$, such that $(\bar{\bar{x}}, y) \in h$. On the one hand, we already established h as a function, so that we may write $y = h(\bar{\bar{x}})$. On the other hand, we see in light of the definition of a domain that $\bar{\bar{x}} \in X$ $[= \mathrm{dom}(h)]$ is true. Because we obtained the disjunction (4.706) for an arbitrary $\bar{x} \in X$, it holds also for the current constant $\bar{x}$, allowing us to prove $h(\bar{\bar{x}}) \in Y$ by corresponding cases. The first case $\bar{x} \in \bigcup_{n=0}^{\infty} u_n$ implies then with (4.704) $h(\bar{x}) = \bar{f}(\bar{x})$, which shows that $\bar{x}$ is in the domain of $\bar{f}$, so that the associated function value $h(\bar{x})$ is in the codomain Y of $\bar{f}$. Similarly, the second case $\bar{x} \in \bigcup_{n=0}^{\infty} u_n$ implies $h(\bar{x}) = \bar{g}^{-1}(\bar{x})$ by definition of the function h; here, $\bar{x}$ is in the domain of $\bar{g}^{-1}$, and therefore the associated function value $h(\bar{x})$ is in the codomain Y of $\bar{g}^{-1}$. We thus found $h(\bar{x}) \in Y$ to be true for both cases, which yields now after substitution based on the previously obtained equation $y = h(\bar{\bar{x}})$ the desired consequent $y \in Y$ of the implication in (4.707). Since y was arbitrary, we may infer from the truth of that implication the truth of the universal sentence (4.707), and consequently the truth of the inclusion $\mathrm{ran}(h) \subseteq Y$. Thus, Y is indeed a codomain of h, so that we may write $h : X \to Y$.

It remains for us to prove that h is a bijection from X to Y, i.e. that h is both an injection and a surjection from X to Y. We first check that h satisfies the definition of an injection, that is,

$$\forall x, x' \, ([x, x' \in X \, \wedge \, h(x) = h(x')] \Rightarrow x = x'). \tag{4.708}$$

For this purpose, we let x and x' be arbitrary, and we assume $x, x' \in X$ and $h(x) = h(x')$. Evidently, $x \in \bigcup_{n=0}^{\infty} u_n$ or $x \notin \bigcup_{n=0}^{\infty} u_n$ is true, which fact allows us in the following to prove $x = x'$ by cases.

In the first case $x \in \bigcup_{n=0}^{\infty} u_n$, which implies $x \in u_{\bar{n}}$ for some particular number $\bar{n} \in \mathbb{N}$ (according to the Characterization of the union of a family of sets), we obtain with (4.703) the equation $u(\bar{n}^+) = F((\bar{n}, u(\bar{n})))$. Clearly, $(\bar{n}, u(\bar{n}))$ is in the domain $\mathbb{N} \times \mathcal{P}(X)$ of the function F, so that there exist due to (4.698) particular constants $\bar{N}, \bar{U}$ satisfying both $(\bar{n}, u(\bar{n})) = (\bar{N}, \bar{U})$ and

$$\bar{g}[\bar{f}[\bar{U}]] = F((\bar{n}, u(\bar{n}))) \quad [= u(\bar{n}^+)].$$

Because the Equality Criterion for ordered pairs yields in particular $u(\bar{n}) = \bar{U}$, the two previously stated equations lead to $u(\bar{n}^+) = \bar{g}[\bar{f}[u(\bar{n})]]$ via substitutions. Now, as the previously found $x \in u_{\bar{n}}$ implies $\bar{g}(\bar{f}(x)) \in \bar{g}[\bar{f}[u(\bar{n})]]$ with (3.739), obtain after substitution based on the preceding equation

$$\bar{g}(\bar{f}(x)) \in u(\bar{n}^+). \tag{4.709}$$

Moreover, we may prove $x' \in \bigcup_{n=0}^{\infty} u_n$ by contradiction, assuming its negation $x' \notin \bigcup_{n=0}^{\infty} u_n$ to be true. Then, the preceding assumption imply with (4.704) $h(x) = \bar{f}(x)$ as well as $h(x') = \bar{g}^{-1}(x')$, so that $h(x) = h(x')$ yields $\bar{f}(x) = \bar{g}^{-1}(x')$ through substitutions. Here, $\bar{f}(x)$ is evidently an element of the codomain Y of $\bar{f}$, and thus an element of the domain of $\bar{g}$. Consequently, $\bar{f}(x)$ gives rise to the value $\bar{g}(\bar{f}(x))$, so that substitution based on the preceding equation gives us

$$\bar{g}(\bar{f}(x)) = \bar{g}(\bar{g}^{-1}(x')) = (\bar{g} \circ \bar{g}^{-1})(x') = \mathrm{id}_{\mathrm{ran}(\bar{g})}(x') = x',$$

using also the notation for compositions functions, (3.680) in connection with $\bar{g} : Y \rightleftarrows \mathrm{ran}(\bar{g})$, and the definition of the identity function. Combining the resulting $x' = \bar{g}(\bar{f}(x))$ with (4.709), we get $x' \in u(\bar{n}^+)$. Observing now that $\bar{n} \in \mathbb{N}$ implies $\bar{n}^+ \in \mathbb{N}$ with (2.297), we thus see that there exists a natural number n for which $x' \in u(n)$ $[= u_n]$ holds. Consequently, we have

$x' \in \bigcup_{n=0}^{\infty} u_n$ according to the Characterization of the union of a family of sets, in contradiction to the assumed negation $x' \notin \bigcup_{n=0}^{\infty} u_n$. Having completed the proof of $x' \in \bigcup_{n=0}^{\infty} u_n$, we recall the current case assumption $x \in \bigcup_{n=0}^{\infty} u_n$ and evaluate these element x, x' by means of (4.704), giving the values $h(x) = \bar{f}(x)$ as well as $h(x') = \bar{f}(x')$. Then, substitution yields $\bar{f}(x) = \bar{f}(x')$, which equation implies in conjunction with the assumed $x, x' \in X$ that $x = x'$ holds, because $\bar{f}$ is an injection with domain X.

In the second case $x \notin \bigcup_{n=0}^{\infty} u_n$, we may simply rearrange the arguments used in the proof of the first case. First, we carry out a proof by contradiction to establish $x' \notin \bigcup_{n=0}^{\infty} u_n$, assuming the negation's negation to be true, so that the Double Negation Law yields the true sentence $x' \in \bigcup_{n=0}^{\infty} u_n$ to be true. This gives us $x' \in u_{\bar{n}'}$ for some particular element $\bar{n}' \in \mathbb{N}$, giving rise to the term $u(\bar{n}'^{+}) = F((\bar{n}', u(\bar{n}')))$ of the recursively defined sequence u. Thus, the ordered pair $(\bar{n}', u(\bar{n}'))$ is in the domain of the function F, ensuring the existence of particular constants $\bar{N}', \bar{U}'$ such that $(\bar{n}', u(\bar{n}')) = (\bar{N}', \bar{U}')$ and

$$\bar{g}[\bar{f}[\bar{U}']] = F((\bar{n}', u(\bar{n}'))) \quad [= u(\bar{n}'^{+})].$$

hold. Here, the equation $(\bar{n}', u(\bar{n}')) = (\bar{N}', \bar{U}')$ yields especially $u(\bar{n}') = \bar{U}'$, which allows us to combine the previous equations to the single equation $u(\bar{n}'^{+}) = \bar{g}[\bar{f}[u(\bar{n}')]]$. Here, we note that $x' \in u_{\bar{n}'}$ implies $\bar{g}(\bar{f}(x')) \in \bar{g}[\bar{f}[u(\bar{n}')]]$, with the consequence that

$$\bar{g}(\bar{f}(x')) \in u(\bar{n}'^{+}). \tag{4.710}$$

In addition, $x \notin \bigcup_{n=0}^{\infty} u_n$ and $x' \in \bigcup_{n=0}^{\infty} u_n$ imply with the definition of the function h the equations $h(x) = \bar{g}^{-1}(x)$ and $h(x') = \bar{f}(x')$, so that the initial assumption $h(x) = h(x')$ yields $\bar{f}(x') = \bar{g}^{-1}(x)$. Here, the value of $\bar{f} : X \to Y$ at x' is in Y and thus in the domain of $\bar{g} : Y \to X$, so that the value $\bar{g}(\bar{f}(x'))$ is specified. Combining these findings and using the definition/property of the identity function, we obtain the equations

$$\bar{g}(\bar{f}(x')) = \bar{g}(\bar{g}^{-1}(x)) = (\bar{g} \circ \bar{g}^{-1})(x) = \mathrm{id}_{\mathrm{ran}(\bar{g})}(x) = x,$$

The resulting equation $x = \bar{g}(\bar{f}(x'))$ and (4.710) lead to $x \in u(\bar{n}'^{+})$, which proves the existence of some $n \in \mathbb{N}$ with $x \in u(n)$ $[= u_n]$, so that $x \in \bigcup_{n=0}^{\infty} u_n$ holds. This however contradicts the current case assumption, completing the proof of $x' \notin \bigcup_{n=0}^{\infty} u_n$. The definition of the function h gives us therefore the values $h(x) = \bar{g}^{-1}(x)$ and $h(x') = \bar{g}^{-1}(x')$, with the consequence that $\bar{g}^{-1}(x) = \bar{g}^{-1}(x')$. Because the bijection $\bar{g}^{-1} : \mathrm{ran}(\bar{g}) \rightleftarrows Y$ is an injection and since the preceding equation clearly shows that x and x' are both in the domain $\mathrm{ran}(\bar{g})$ of $\bar{g}^{-1}$, it follows from this and the previous equation that $x = x'$ is true.

We thus completed the proof by cases, and thus the proof of the implication in (4.708), in which x and x' were arbitrary, so that the universal sentence (4.708) follows to be true. This means that the function $h : X \to Y$ is an injection. Our final task is now to prove that this injection $h : X \hookrightarrow Y$ is a surjection from X to Y, i.e. that Y is the range of h. We already know that the range of h is included in Y, so that it suffices to prove that Y is included in the range of h, because the truth of these two inclusion will imply the desired equality $Y = \operatorname{ran}(h)$ by means of the Axiom of Extension. Now, to prove the required $Y \subseteq \operatorname{ran}(h)$, we apply once again the definition of a subset and establish the equivalent universal sentence

$$\forall y\, (y \in Y \Rightarrow y \in \operatorname{ran}(h)), \tag{4.711}$$

letting y be arbitrary and assuming that $y \in Y$ holds. Since Y is the domain of $\bar{g}$, it follows that the value $\bar{g}(y)$ is in the codomain X of $\bar{g}$. Because the disjunction $\bar{g}(y) \in \bigcup_{n=0}^{\infty} u_n \lor \bar{g}(y) \notin \bigcup_{n=0}^{\infty} u_n$ is true (according to the Law of the Excluded Middle), we may prove $y \in \operatorname{ran}(h)$ by cases.

The first case $\bar{g}(y) \in \bigcup_{n=0}^{\infty} u_n$ implies (according to the Characterization of the union of a family of sets) that $\bar{g}(y) \in u_{\bar{n}}$ holds for some particular $\bar{n} \in \mathbb{N}$. Clearly, the value $\bar{g}(y)$ is also in the range of $\bar{g}$, so that the negation $\neg \bar{g}(y) \in \operatorname{ran}(\bar{g})$ is false. Therefore, the conjunction $\bar{g}(y) \in X \land \bar{g}(y) \notin \operatorname{ran}(\bar{g})$ is false as well, which means by definition of a set difference that $\bar{g}(y) \in X \setminus \operatorname{ran}(\bar{g})$ is false. In view of (4.702), this means that $\bar{g}(y) \notin u(0)$ holds. We may now prove by contradiction that $\bar{n} \neq 0$ is then also true. Indeed, assuming $\neg \bar{n} \neq 0$ to be true, we obtain $\bar{n} = 0$ with the Double Negation Law, so that the previously found $\bar{g}(y) \in u_{\bar{n}}$ gives via substitution $\bar{g}(y) \in u_0$ $[= u(0)]$, in contradiction to the true sentence $\bar{g}(y) \notin u(0)$. Having thus proved $\bar{n} \neq 0$ (where $\bar{n} \in \mathbb{N}$), it follows with (4.39) that there exists a natural number, say $\bar{m}$, satisfying $\bar{m} \neq \bar{n}$ and $\bar{m}^+ = \bar{n}$. Here, $\bar{m} \in \mathbb{N}$ gives rise to the value $u(\bar{m}^+) = F((\bar{m}, u(\bar{m})))$ according to (4.703), which we may write also as $u(\bar{n}) = F((\bar{m}, u(\bar{m})))$ after substitution. This equation shows that the ordered pair $(\bar{m}, u(\bar{m}))$ is in the domain of F, so that we obtain with (4.698) particular constants $\bar{N}, \bar{U}$ satisfying $(\bar{m}, u(\bar{m})) = (\bar{N}, \bar{U})$ as well as $\bar{g}[\bar{f}[\bar{U}]] = F((\bar{m}, u(\bar{m})))$. We can apply here the Equality Criterion for ordered pairs to obtain first $u(\bar{m}) = \bar{U}$ and therefore

$$\bar{g}[\bar{f}[\bar{U}]] = F((\bar{m}, u(\bar{m}))) \quad [= u(\bar{n})]$$

via substitution, resulting in the equation $u(\bar{n}) = \bar{g}[\bar{f}[u(\bar{m})]]$. Recalling now the previous finding $\bar{g}(y) \in u_{\bar{n}}$, we obtain now (by means of substitution) also $\bar{g}(y) \in \bar{g}[\bar{f}[u(\bar{m})]]$. Noting the truth of the equations

$$\bar{g}[\bar{f}[u(\bar{m})]] = (\bar{g} \circ \bar{f})[u(\bar{m})] = \operatorname{ran}((\bar{g} \circ \bar{f}) \restriction u(\bar{m}))$$

in light of (3.724) and the definition of an image, we get

$$\bar{g}(y) \in \operatorname{ran}((\bar{g} \circ \bar{f}) \restriction u(\bar{m}))$$

via substitution. By definition of a range, there exists then a constant, say $\bar{x}$, for which

$$(\bar{x}, \bar{g}(y)) \in (\bar{g} \circ \bar{f}) \restriction u(\bar{m})$$

holds. This implies with the definition of a restriction that $(\bar{x}, \bar{g}(y)) \in \bar{g} \circ \bar{f}$ and $\bar{x} \in u(\bar{m})$ are true, where we may write the former finding also as $\bar{g}(y) = \bar{g}(\bar{f}(\bar{x}))$, using the notation for function compositions. Since we assumed $y \in Y$ and since the value $\bar{f}(\bar{x})$ is clearly an element of the codomain Y of $\bar{f}$, we thus have $y, \bar{f}(\bar{x}) \in Y$. In conjunction with the preceding equation, this implies now $y = \bar{f}(\bar{x})$ with the injectivity of $\bar{g}$. We now draw two conclusions from the previous finding $\bar{x} \in u(\bar{m})$. On the one, recalling that $\mathcal{P}(X)$ is a codomain of u, we clearly have $u(\bar{m}) \in \mathcal{P}(X)$ and therefore $u(\bar{m}) \subseteq X$ (by definition of a power set), so that $\bar{x} \in u(\bar{m})$ gives $\bar{x} \in X$ (by definition of a subset). On the other hand, $\bar{x} \in u(\bar{m})$ implies in conjunction with $\bar{m} \in \mathbb{N}$ the truth of $\bar{x} \in \bigcup_{n=0}^{\infty} u_n$ (according to the Characterization of the union of a family of sets). Because of $\bar{x} \in X$, the latter conclusion implies $h(\bar{x}) = \bar{f}(\bar{x})$ by definition of the function h in (4.704). Combining this with the previously found equation $y = \bar{f}(\bar{x})$, we obtain $y = h(\bar{x})$ by substitution. Writing this in the form $(\bar{x}, y) \in h$, it is now clear that $y \in \operatorname{ran}(h)$ holds (in view of the definition of a range). Thus, the desired consequent of the implication in (4.711) is true in the first case.

In the second case $\bar{g}(y) \notin \bigcup_{n=0}^{\infty} u_n$, we recall the truth of $\bar{g}(y) \in X$ and use the definition of the function h to obtain

$$h(\bar{g}(y)) = \bar{g}^{-1}(\bar{g}(y)) = (\bar{g}^{-1} \circ \bar{g})(y) = \mathrm{id}_Y(y) = y,$$

applying also (3.679) and the definition of the identity function based on $\bar{g} : Y \rightleftarrows \operatorname{ran}(\bar{g})$. We can write the resulting equation $y = h(\bar{g}(y))$ also in the form $(\bar{g}(y), y) \in h$, so that we see (in light of the definition of a range) that $y \in \operatorname{ran}(h)$ follows to be true also for the current second case.

Because y was arbitrary, we may therefore conclude that the universal sentence (4.711) holds, and this sentence gives us the equivalent inclusion $Y \subseteq \operatorname{ran}(h)$. In conjunction with the already established reversed inclusion $\operatorname{ran}(h) \subseteq Y$, this implies $Y = \operatorname{ran}(h)$, so that the injection $h : X \hookrightarrow Y$ is a surjection from X to Y, thus a bijection from X to Y. This proves the existential sentence $\exists f\,(f : X \rightleftarrows Y)$, which means that X and Y are equinumerous (by definition), symbolically $X \sim Y$. We thus completed the proof of the implication in (4.697), where the sets X and Y were initially arbitrary, so that the stated theorem is indeed true. $\square$

4.8. Matrices

Definition 4.19 (Matrix, dimensions of a matrix, number of rows, number of columns, entry, row, column, row vector, column vector, vector). For any positive natural numbers m, n and any nonempty set Y, we say that a set $\boldsymbol{A}$ is a *matrix* iff $\boldsymbol{A}$ is a function from the Cartesian product of the initial segment of $\mathbb{N}_+$ up to m and the initial segment of $\mathbb{N}_+$ up to n to Y, that is, iff

$$\boldsymbol{A} : \{1, \ldots, m\} \times \{1, \ldots, n\} \to Y. \tag{4.712}$$

Here, we call m and n the *dimensions of* $\boldsymbol{A}$, and we say that $\boldsymbol{A}$ is a matrix of dimensions m and n or an $(m \times n)$-matrix or an m-by-n matrix (with values in Y). Furthermore, we call m the *number of rows* and n the *number of columns* of $\boldsymbol{A}$.

Moreover, for any $i \in \{1, \ldots, m\}$ and any $j \in \{1, \ldots, n\}$, we call the function value

$$a_{i,j} = \boldsymbol{A}((i,j)) \tag{4.713}$$

an *entry* of $\boldsymbol{A}$, and we write

$$\boldsymbol{A} = \begin{bmatrix} a_{1,1} & \cdots & a_{1,n} \\ \vdots & \ddots & \vdots \\ a_{m,1} & \cdots & a_{m,n} \end{bmatrix}. \tag{4.714}$$

In addition, we call the restrictions

$$\boldsymbol{A}_i = \boldsymbol{A} \upharpoonright \{i\} \times \{1, \ldots, n\}, \tag{4.715}$$

$$\boldsymbol{A}^{(j)} = \boldsymbol{A} \upharpoonright \{1, \ldots, m\} \times \{j\}, \tag{4.716}$$

respectively, the ith *row* and the jth *column* of $\boldsymbol{A}$.

In case of $m = 1$, we symbolize a $(1 \times n)$-matrix $\boldsymbol{A}$ also by

$$\boldsymbol{a} = \begin{bmatrix} a_1 & \cdots & a_n \end{bmatrix} = \begin{bmatrix} a_{1,1} & \cdots & a_{1,n} \end{bmatrix} \tag{4.717}$$

and call $\boldsymbol{a}$ a (n-dimensional) *row vector*; similarly, in case of $n = 1$, we write for an $(m \times 1)$-matrix $\boldsymbol{A}$ also

$$\boldsymbol{a} = \begin{bmatrix} a_1 \\ \vdots \\ a_m \end{bmatrix} = \begin{bmatrix} a_{1,1} \\ \vdots \\ a_{m,1} \end{bmatrix} \tag{4.718}$$

and speak of a (m-dimensional) *column vector*. In both cases, we call $\boldsymbol{a}$ also simply a *vector*.

Note 4.27. The vector concept (4.718) differs from that of the n-vector (4.383) (here with $n = m$) both in structure and notation. Whereas the former is a function

$$\boldsymbol{a} : \{1, \ldots, m\} \times \{1\} \to Y, \tag{4.719}$$

the latter is a function

$$\boldsymbol{a} : \{1, \ldots, m\} \to Y. \tag{4.720}$$

Notation 4.9. In view of Proposition 3.164, the restrictions (4.715) and (4.716) are the functions $\boldsymbol{A}_i : \{i\} \times \{1, \ldots, n\} \to Y$ and $\boldsymbol{A}^{(j)} = \{1, \ldots, m\} \times \{j\} \to Y$, respectively, which we symbolize by

$$\boldsymbol{A}_i = \begin{bmatrix} a_{i,1} & \cdots & a_{i,n} \end{bmatrix} \tag{4.721}$$

$$\boldsymbol{A}^{(j)} = \begin{bmatrix} a_{1,j} \\ \vdots \\ a_{m,j} \end{bmatrix}. \tag{4.722}$$

Notation 4.10. Applying the notion of a set of functions to matrices, we now define the set of m-by-n matrices with values in Y and use the convenient abbreviation

$$Y^{m \times n} = Y^{\{1,\ldots,m\} \times \{1,\ldots,n\}}. \tag{4.723}$$

Proposition 4.149. *It is true for any m-by-n matrix $\boldsymbol{A}$ with values in any set Y that*

a) there exists a unique function $\boldsymbol{A}^T$ with domain $\{1, \ldots, n\} \times \{1, \ldots, m\}$ such that

$$\forall z \, (z \in \{1, \ldots, n\} \times \{1, \ldots, m\} \Rightarrow \exists i, j \, (i \in \{1, \ldots, n\} \wedge j \in \{1, \ldots, m\} \wedge (i, j) = z \wedge \boldsymbol{A}^T((i, j)) = a_{j,i}). \tag{4.724}$$

b) the function $\boldsymbol{A}^T$ is an n-by-m matrix with values in Y whose entries are given by

$$\forall i, j \, ([i \in \{1, \ldots, n\} \wedge j \in \{1, \ldots, m\}] \Rightarrow a^T_{i,j} = a_{j,i}). \tag{4.725}$$

Proof. Letting $\boldsymbol{A}$ be an arbitrary m-by-n matrix in an arbitrary set Y, we apply Function definition by replacement to establish the desired matrix. For this purpose, we prove

$$\forall z \, (z \in \{1, \ldots, n\} \times \{1, \ldots, m\} \Rightarrow \exists! y \, (\exists i, j \, (i \in \{1, \ldots, n\} \wedge j \in \{1, \ldots, m\} \wedge (i, j) = z \wedge y = a_{j,i})). \tag{4.726}$$

Letting $z \in \{1,\ldots,n\} \times \{1,\ldots,m\}$ be arbitrary, there are particular elements $I \in \{1,\ldots,n\}$ and $J \in \{1,\ldots,m\}$ such that $(I,J) = z$, according to Exercise 3.4. Therefore, the ordered pair (J,I) is an element of the Cartesian product $\{1,\ldots,m\} \times \{1,\ldots,n\}$, thus an element of the domain of the matrix $\boldsymbol{A}$. The associated entry is given by $\boldsymbol{A}((J,I)) = a_{J,I}$. These findings demonstrate the truth of the existential sentence

$$\exists i,j\,(i \in \{1,\ldots,n\} \wedge j \in \{1,\ldots,m\} \wedge (i,j) = z \wedge \boldsymbol{A}((J,I)) = a_{j,i}),$$

which in turn demonstrates the truth of the existential part of the uniquely existential sentence in (4.726). To establish the uniqueness part, we let y and y' be arbitrary, assuming $y = a_{j,i}$ and $y' = a_{j',i'}$ to be satisfied by some particular elements $i,i' \in \{1,\ldots,n\}$ and $j,j' \in \{1,\ldots,m\}$ with $(i,j) = z$ and $(i',j') = z$. The last two equations imply $(i,j) = (i',j')$ via substitution, so that the Equality Criterion for ordered pairs yields the true equations $i = i'$ and $j = j'$. Consequently, the previous equations for y and y' become $y = a_{j,i} = a_{j',i'} = y'$ after carrying out substitutions. Since y and y' are arbitrary, the resulting equation $y = y'$ implies the truth of the uniqueness part of the uniquely existential sentence in (4.726). As z was also arbitrary, we may therefore conclude that the universal sentence (4.726) holds, which in turn implies the unique existence of a function $\boldsymbol{A}^T$ on $\{1,\ldots,n\} \times \{1,\ldots,m\}$ such that (4.724). Next, we prove that Y is a codomain of that function, i.e., that the range of $\boldsymbol{A}^T$ is included in Y. To do this, we apply the definition of a subset and let accordingly $\bar{y} \in \mathrm{ran}(\boldsymbol{A}^T)$ be arbitrary. By definition of a range, there exists then a particular constant $\bar{z} \in \{1,\ldots,n\} \times \{1,\ldots,m\}$ such that $(\bar{z},\bar{y}) \in \boldsymbol{A}^T$. Since $\boldsymbol{A}^T$ constitutes a function, we may write this finding as $\bar{y} = \boldsymbol{A}^T(\bar{z})$. By definition of a domain, we also find $\bar{z} \in \{1,\ldots,n\} \times \{1,\ldots,m\}$, so that (4.724) yields $\boldsymbol{A}^T((i,j)) = a_{j,i}$ for some particular elements $i \in \{1,\ldots,n\}$ and $j \in \{1,\ldots,m\}$ satisfying $(i,j) = \bar{z}$. Substitution therefore gives us $[\bar{y} =\,]\ \boldsymbol{A}^T(\bar{z}) = a_{j,i}\ [= \boldsymbol{A}((j,i))]$. As $\boldsymbol{A}$ is a function from $\{1,\ldots,m\} \times \{1,\ldots,n\}$ to Y, the resulting equation $\bar{y} = \boldsymbol{A}((j,i))$ implies $\bar{y} \in Y$ with (3.517). Since $\bar{y}$ was arbitrary, we may therefore conclude that the inclusion $\mathrm{ran}(\boldsymbol{A}^T) \subseteq Y$ is true indeed, so that $\boldsymbol{A}^T$ is a function from $\{1,\ldots,n\} \times \{1,\ldots,m\}$ to Y. Thus, $\boldsymbol{A}^T$ constitutes an n-by-m matrix with values in Y.

It remains for us to establish (4.725). For this purpose, we let $i \in \{1,\ldots,n\}$ and $j \in \{1,\ldots,m\}$ be arbitrary, with the consequence that (i,j) is an element of the Cartesian product $\{1,\ldots,n\} \times \{1,\ldots,m\}$, thus of the domain of $\boldsymbol{A}^T$. By definition of that function, there exist then particular elements $I \in \{1,\ldots,n\}$ and $J \in \{1,\ldots,m\}$ satisfying $(I,J) = (i,j)$ and $\boldsymbol{A}^T((I,J)) = a_{J,I}$. Clearly, the former equation implies $I = i$ and $J = j$, so that the other equation can be re-expressed as $\boldsymbol{A}^T((i,j)) = a_{j,i}$. Writing $a^T_{i,j}$ for $\boldsymbol{A}^T((i,j))$ as in (4.713), we therefore obtain $a^T_{i,j} = a_{j,i}$, which proves the implication in (4.725). Since i and j are arbitrary, we may infer from the truth of that implication the truth of the universal sentence (4.725). Since $\boldsymbol{A}$ was initially an arbitrary m-by-n matrix in an arbitrary set Y, we may now further conclude that the proposed universal sentence is true. □

Definition 4.20 (Transpose of a matrix). For any m-by-n matrix $\boldsymbol{A}$ with values in any set Y, we call the n-by-m matrix

$$\boldsymbol{A}^T \tag{4.727}$$

with values in Y the *transpose of* $\boldsymbol{A}$.

Theorem 4.150 (Double Transposition Law). *Every m-by-n matrix $\boldsymbol{A}$ with values in any set Y is identical with the transpose of its transpose, that is,*

$$(\boldsymbol{A}^T)^T = \boldsymbol{A}. \tag{4.728}$$

Exercise 4.51. Prove the Double Transposition Law.

(Hint: Apply the Equality Criterion for functions and (4.725).)

Besides vectors, the following types of matrices also play a prominent role in real matrix calculus.

Definition 4.21 (Square matrix, main diagonal). We say that an $(m \times n)$-matrix $\boldsymbol{A}$ is a *square matrix* (*of order* n) iff its dimensions are identical, that is, iff

$$m = n. \tag{4.729}$$

Then, we call for any square matrix of order n

$$\boldsymbol{A} = \begin{bmatrix} a_{1,1} & \cdots & a_{1,n} \\ \vdots & \ddots & \vdots \\ a_{n,1} & \cdots & a_{n,n} \end{bmatrix} \tag{4.730}$$

the restriction

$$\boldsymbol{A} \upharpoonright \{(i,i) : i \in \{1,\ldots,n\}\} \tag{4.731}$$

the *main diagonal* of $\boldsymbol{A}$, and we call each value $a_{i,i}$ of the main diagonal a *main diagonal entry* of $\boldsymbol{A}$.

Definition 4.22 (Symmetric matrix). We say that a square matrix $\boldsymbol{A}$ of any order n is *symmetric* iff $\boldsymbol{A}$ and its transpose are identical, that is, iff

$$\boldsymbol{A}^T = \boldsymbol{A}. \tag{4.732}$$

Chapter 5.

The Ordered Elementary Domain of Natural Numbers

5.1. Binary Operations

In Part a) of the Strong Recursion Theorem we encountered a function f whose domain is given by a Cartesian product $N \times B^{<\mathbb{N}}$, which function we may therefore recognize as a ternary relation. In the current chapter, we will in particular define ternary relations for which the domain is a Cartesian product of two identical sets.

Definition 5.1 (Binary operation). For any set X we say that a set $*$ is a *binary operation* on X iff $*$ is a function from $X \times X$ to X, i.e. iff

$$* : X \times X \to X. \tag{5.1}$$

Notation 5.1. We then write $(a, b) \mapsto *(a, b) = a * b$. The symbol $*$ may be viewed as a placeholder for specific binary operations that typically arise in dealing with sets, numbers and functions. Instead of $*$ we will also use the symbol $\odot$ to denote a generic binary operation.

Definition 5.2 (Restricted binary operation). For any set X, any set $A \subseteq X$ and any binary operation $*$ on X, we say that the restriction of $*$ to $A \times A$ is a *restricted binary operation* iff it constitutes a binary operation on A, i.e., iff

$$* \restriction A \times A : A \times A \to A. \tag{5.2}$$

Note 5.1. The restriction of a binary operation on a set X to the Cartesian product of a subset $A \subseteq X$ with itself always constitutes a function

$$* \restriction A \times A : A \times A \to X. \tag{5.3}$$

in view of (3.566); however, A need not be a codomain of that restriction, so that the restriction is not necessarily a binary operation itself.

Proposition 5.1. *The following universal sentence holds for any set X, any set $A \subseteq X$ and any binary operation $*$ on X such that the restriction $*_A$ of $*$ to $A \times A$ is a binary operation on A:*

$$\forall a, b\,(a, b \in A \Rightarrow a * b = a *_A b). \tag{5.4}$$

Proof. We let $*$ be an arbitrary binary operation on an arbitrary set X and A an arbitrary subset of X such that the restriction $*_A = * \restriction A \times A$ is a binary operation on A. For arbitrary $a, b \in A$, we obtain

$$a *_A b = *_A(a, b) = * \restriction A \times A(a, b) = *(a, b) = a * b$$

by applying Notation 5.1, the definition of $*_A$, (3.567) with the evident fact that $a, b \in A$ implies $(a, b), (b, a)$ in $A \times A$ with the definition of the Cartesian product of two sets, and finally again Notation 5.1. Thus, $a *_A b = a * b$ follows to be true, and since X, A, $*$, a and b were initially all arbitrary, we may therefore conclude that the proposed universal sentence is true. □

We now give a first example of a binary operation.

Proposition 5.2. *For any lattice $(X, \leq_X)$ there exist the binary operations*

$$\sqcup : X \times X \to X, \quad (a, b) \mapsto a \sqcup b = \sup\{a, b\}, \tag{5.5}$$

$$\sqcap : X \times X \to X, \quad (a, b) \mapsto a \sqcap b = \inf\{a, b\}. \tag{5.6}$$

Proof. Letting X and $\leq_X$ be arbitrary such that $(X, \leq_X)$ is a lattice, we may apply Function definition by replacement to establish (5.5). For this purpose, we first verify the universal sentence

$$\forall Z\,(Z \in X \times X \Rightarrow \exists! y\,(\exists a, b\,(y = \sup\{a, b\} \,\wedge\, (a, b) = Z))). \tag{5.7}$$

Letting Z be arbitrary and assuming $Z \in X \times X$ to be true, it follows with the definition of the Cartesian product of two sets that there are constants, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in X$, $\bar{b} \in X$ and $(\bar{a}, \bar{b}) = Z$ hold. Then, regarding the existential part, we observe that $\bar{a}, \bar{b} \in X$ implies the existence of the supremum $\sup\{\bar{a}, b\}$, because $(X, <_X)$ is a lattice; together with the preceding equation, this shows that there are constants y, a and b which satisfy $y = \sup\{a, b\} \,\wedge\, (a, b) = Z$. Regarding the uniqueness part, we let y and y' be arbitrary such that the existential sentences

$$\exists a, b\,(y = \sup\{a, b\} \,\wedge\, (a, b) = Z)$$
$$\exists a, b\,(y' = \sup\{a, b\} \,\wedge\, (a, b) = Z)$$

are both true. Thus, there are particular constants $\bar{\bar{a}}, \bar{\bar{b}}$ satisfying $y = \sup\{\bar{\bar{a}}, \bar{\bar{b}}\}$ and

$$(\bar{\bar{a}}, \bar{\bar{b}}) = Z\ [= (\bar{a}, \bar{b})],$$

as well as particular constants $\bar{\bar{a}}', \bar{\bar{b}}'$ such that $y' = \sup\{\bar{\bar{a}}', \bar{\bar{b}}'\}$ and

$$(\bar{\bar{a}}', \bar{\bar{b}}') = Z \quad [= (\bar{a}, \bar{b})]$$

hold. The equations involving the ordered pairs imply now with the Equality Criterion for ordered pairs $\bar{\bar{a}} = \bar{a}$ and $\bar{\bar{b}} = \bar{b}$ as well as $\bar{\bar{a}}' = \bar{a}$ and $\bar{\bar{b}}' = \bar{b}$. Then, the preceding equations for y and y' become (after carrying out substitutions) $y = \sup\{\bar{a}, \bar{b}\}$ and $y' = \sup\{\bar{a}, \bar{b}\}$ $[= y]$, so that we obtain $y = y'$. Since y and y' are arbitrary, we may therefore conclude that the uniqueness part also holds, completing the proof of the uniquely existential sentence in (5.7). As Z was also arbitrary, we may further conclude that the universal sentence (5.7) holds. which in turn implies that there exists a unique function $\sqcup$ with domain $X \times X$ such that

$$\forall Z \,(Z \in X \times X \Rightarrow \exists a, b \,(\sqcup(Z) = \sup\{a, b\} \,\wedge\, (a, b) = Z)) \tag{5.8}$$

holds. Let us now verify that $\sqcup$ maps indeed every ordered pair $(a, b) \in X \times X$ to $\sup\{a, b\}$, in the sense of

$$\forall a, b \,((a, b) \in X \times X \Rightarrow \sqcup(a, b) = \sup\{a, b\}). \tag{5.9}$$

Letting a and b be arbitrary and assuming $(a, b) \in X \times X$ to be true, it follows with (5.8) that there are constants, say $\bar{a}$ and $\bar{b}$, with $\sqcup(a, b) = \sup\{\bar{a}, \bar{b}\}$ and $(\bar{a}, \bar{b}) = (a, b)$ are true. The latter equation yields $\bar{a} = a$ and $\bar{b} = b$ with the Equality Criterion for ordered pairs, so that the former equation yields $\sqcup(a, b) = \sup\{a, b\}$ via substitution. Since a and b are arbitrary, we may infer from this the truth of (5.9), which shows that the function $\sqcup$ is indeed characterized by the mapping $(a, b) \mapsto \sup\{a, b\}$. According to Notation 3.2, we may then write for this mapping by $\sqcup$ also $(a, b) \mapsto a \sqcup b$.

It now remains for us to show that X is a codomain of $\sqcup$, i.e. that the range of $\sqcup$ is included in X. To do this, we verify

$$\forall y \,(y \in \operatorname{ran}(\sqcup) \Rightarrow y \in X). \tag{5.10}$$

We take an arbitrary $\bar{y}$ and assume that $\bar{y} \in \operatorname{ran}(\sqcup)$ is true. It then follows with the definition of a range that there is a constant, say $\bar{Z}$, with $(\bar{Z}, \bar{y}) \in \sqcup$. Therefore, we obtain $\bar{Z} \in X \times X$ $[= \operatorname{dom}(\sqcup)]$ with the definition of a domain, so that there are (by definition of the Cartesian product of two sets) constants, say $\bar{a}$ and $\bar{b}$, such that $\bar{a} \in X$, $\bar{b} \in X$ and $(\bar{a}, \bar{b}) = \bar{Z}$ hold. With the latter equation, $(\bar{Z}, \bar{y}) \in \sqcup$ evidently yields $((\bar{a}, \bar{b}), \bar{y}) \in \sqcup$ via substitution, which we may also write as $\bar{y} = \bar{a} \sqcup \bar{b} = \sup\{\bar{a}, \bar{b}\}$. As this supremum is taken with respect to the partial ordering $\leq_X$, it is an element of X according to Note 3.12, so that we obtain the desired $\bar{y} \in X$ with the preceding equations. Since $\bar{y}$ is arbitrary, we may therefore conclude that the universal sentence (5.10) is true, so that $\mathrm{ran}(\sqcup) \subseteq X$ follows to be true by definition of a subset. Thus, $\sqcup$ is a function from $X \times X$ to X, and the proof of the existence of the function (5.5) is complete. As X and $\leq_X$ were arbitrary, we may further conclude that this binary operation exists for any X and any $\leq_X$. $\square$

Exercise 5.1. Establish the existence of the function (5.6).

Notation 5.2. We will also write for a lattice $(X, \leq)$

$$(X, \sqcup, \sqcap, \leq). \tag{5.11}$$

Here, we call $\sqcup$ the *join* and $\sqcap$ the *meet*.

We now apply the preceding proposition to the lattice established in Corollary 3.115.

Proposition 5.3. *For any x it is true that the join with respect to the lattice $(\{x\}, \{(x,x)\})$ is given by*

$$\sqcup = \{((x,x),x)\}. \tag{5.12}$$

Proof. Letting x be arbitrary, we denote the set $\{((x,x),x)\}$ by f and apply (3.39) to obtain the equations

$$f = \{((x,x),x)\} \tag{5.13}$$
$$= \{(x,x)\} \times \{x\} \tag{5.14}$$
$$= (\{x\} \times \{x\}) \times \{x\}. \tag{5.15}$$

Therefore, f is a function from $\{x\} \times \{x\}$ to $\{x\}$ according to Proposition 3.153. Since $\sqcup$ is also a function from $\{x\} \times \{x\}$ to $\{x\}$ according to (5.5), we may apply the Equality Criterion for functions to prove $\sqcup = f$. For this purpose, we verify

$$\forall Z\,(Z \in \{x\} \times \{x\} \Rightarrow \sqcup(Z) = f(Z)). \tag{5.16}$$

We let Z be arbitrary and assume $Z \in \{x\} \times \{x\}$ $[= \{(x,x)\}]$ to be true, which yields $Z = (x,x)$ with (2.169). Because $\sqcup$ is a function (which thus satisfies Corollary 3.150), the preceding equation implies

$$\sqcup(Z) = \sqcup((x,x)) = x \sqcup x = \sup\{x,x\}$$

where we used also (5.5). Now, since the equation $\{x,x\} = \{x\}$ holds by definition of a singleton, we obtain

$$\sqcup(Z) = \sup\{x\} = x \tag{5.17}$$

by applying substitution and then Corollary 3.106 (based on the fact that the lattice $(\{x\},\{(x,x)\})$ is partially ordered). Furthermore, since $((x,x),x) \in \{((x,x),x)\}$ holds because of (2.153), equation (5.13) gives $((x,x),x) \in f$ by substitution, and therefore the previously established equation $Z = (x,x)$ yields $(Z,x) \in f$ again via substitution. We may write this also as $x = f(Z)$, which we may now substitute into (5.17) to arrive at the desired equation $\sqcup(Z) = f(Z)$. As Z was arbitrary, we may infer from this finding the truth of (5.16), so that $\sqcup = \{((x,x),x)\}$ $[= f]$ follows to be true (with the Equality Criterion for functions). Since x was also arbitrary, we may further conclude that the proposition holds. □

Exercise 5.2. Show for any x that the meet with respect to the lattice $(\{x\},\{(x,x)\})$ is given by

$$\sqcap = \{((x,x),x)\}. \tag{5.18}$$

Note 5.2. In view of Notation 5.2 and the equations (5.12) & (5.18), we may write the lattice $(\{x\},\{(x,x)\})$ also as

$$(\{x\},\{((x,x),x)\},\{((x,x),x)\},\{(x,x)\}). \tag{5.19}$$

Proposition 5.4. *For any x, y it is true that the meet with respect to the lattice $(\{x,y\},\{(x,x),(x,y),(y,y)\})$ is given by the quadruple*

$$\sqcap = \{((x,x),x),((x,y),x),((y,x),x),((y,y),y)\}. \tag{5.20}$$

Proof. We let x and y be arbitrary and introduce the notation

$$f = \{((x,x),x),((x,y),x),((y,x),x),((y,y),y)\},$$

so that we obtain the true sentences

$$((x,x),x) \in f \tag{5.21}$$
$$((x,y),x) \in f \tag{5.22}$$
$$((y,x),x) \in f \tag{5.23}$$
$$((y,y),y) \in f \tag{5.24}$$

with (2.244). Let us now observe that

$$(x,x),(x,y),(y,y) \in \{(x,x),(x,y),(y,y)\}$$

holds according to (2.233), where the triple is the total ordering $\leq_X$ of $X = \{x,y\}$ in the given lattice. Therefore, the inequalities $x \leq_X x$, $x \leq_X y$

and $y \leq_Y y$ are true, which then further imply the three corresponding equations

$$\inf\{x, x\} = x, \tag{5.25}$$
$$\inf\{x, y\} = x, \tag{5.26}$$
$$\inf\{y, y\} = y \tag{5.27}$$

with Proposition 3.109. Moreover, since $\{x, y\} = \{y, x\}$ is true according to (2.161), we see that (5.26) yields

$$\inf\{y, x\} = x \tag{5.28}$$

via substitution. By definition of the meet $\sqcap$, we may now write the equations for the four infima as

$$x \sqcap x = x, \tag{5.29}$$
$$x \sqcap y = x, \tag{5.30}$$
$$y \sqcap x = x, \tag{5.31}$$
$$y \sqcap y = y, \tag{5.32}$$

and then in binary relation notation as

$$((x, x), x) \in \sqcap, \tag{5.33}$$
$$((x, y), x) \in \sqcap, \tag{5.34}$$
$$((y, x), x) \in \sqcap, \tag{5.35}$$
$$((y, y), y) \in \sqcap. \tag{5.36}$$

We now apply the Equality Criterion for sets to establish equation (5.20) and prove the universal sentence

$$\forall Z\, (Z \in \sqcap \Leftrightarrow Z \in f). \tag{5.37}$$

We take an arbitrary Z and assume first $Z \in \sqcap$ to be true. Being a function from $\{x, y\} \times \{x, y\}$ to $\{x, y\}$, the binary operation $\sqcap$ is included in $(\{x, y\} \times \{x, y\}) \times \{x, y\}$ according to (3.514), so that the preceding assumption yields $Z \in (\{x, y\} \times \{x, y\}) \times \{x, y\}$ with the definition of a subset. This finding further implies with Exercise 3.4 that there are particular elements $\bar{Y} \in \{x, y\} \times \{x, y\}$ and $\bar{c} \in \{x, y\}$ with $(\bar{Y}, \bar{c}) = Z$. Here, $\bar{Y} \in \{x, y\} \times \{x, y\}$ implies again with Exercise 3.4 that there are particular elements $\bar{a} \in \{x, y\}$ and $\bar{b} \in \{x, y\}$ with $(\bar{a}, \bar{b}) = \bar{Y}$. Applying now substitution based on this equation, the previously established $Z = (\bar{Y}, \bar{c})$ gives $Z = ((\bar{a}, \bar{b}), \bar{c})$, and therefore the assumed $Z \in \sqcap$ yields $((\bar{a}, \bar{b}), \bar{c}) \in \sqcap$, which we may also write in function notation as

$$\begin{aligned} \bar{c} &= \sqcap((\bar{a}, \bar{b})) = \bar{a} \sqcap \bar{b} \\ &= \inf\{\bar{a}, \bar{b}\}, \end{aligned} \tag{5.38}$$

because $\sqcap$ is a function/binary operation according to (5.6). As the previously obtained $\bar{a} \in \{x, y\}$ implies the disjunction $\bar{a} = x \lor \bar{a} = y$ with the definition of a pair, we may now apply a proof by cases to establish the desired sentence $Z \in f$.

In the first case $\bar{a} = x$, we observe that the previously found $\bar{b} \in \{x, y\}$ gives the additional disjunction $\bar{b} = x \lor \bar{b} = y$, which allows us to consider two subcases to prove $Z \in f$. On the one hand, if $\bar{b} = x$ is true, then the equation (5.38) gives in connection with (5.25) $\bar{c} = \inf\{x, x\} = x$ and therefore $\bar{c} = x$. Furthermore, $\bar{a} = x$ and $\bar{b} = x$ imply with the Equality Criterion for ordered pairs $[\bar{Y} =]$ $(\bar{a}, \bar{b}) = (x, x)$, so that $Y = (x, x)$ and $\bar{c} = x$ imply (again with the Equality Criterion for ordered pairs) $[Z =]$ $(\bar{Y}, \bar{c}) = ((x, x), x)$. In view of these equations, we now see that (5.21) implies the desired $Z \in f$ for the first subcase. On the other hand, if $\bar{b} = y$ holds, then (5.38) yields together with (5.26) $\bar{c} = \inf\{x, y\} = x$. Applying now substitutions based on the true equations $\bar{a} = x$, $\bar{b} = y$ and $\bar{c} = x$, we obtain first $[\bar{Y} =]$ $(\bar{a}, \bar{b}) = (x, y)$ and then $[Z =]$ $(\bar{Y}, \bar{c}) = ((x, y), x)$ with the Equality Criterion for ordered pairs. Therefore, (5.22) yields $Z \in f$ also for the second subcase, so that the proof for the first case $(\bar{a} = y)$ is complete.

In the second case $\bar{a} = y$, we may consider the same two subcases and apply essentially the same arguments as in the first case to prove $Z \in f$. On the one hand, if $\bar{b} = x$ holds, then (5.38) and (5.28) imply $\bar{c} = \inf\{y, x\} = x$, thus $\bar{c} = x$. Together with $\bar{a} = y$ and $\bar{b} = x$, this evidently yields $[\bar{Y} =]$ $(\bar{a}, \bar{b}) = (y, x)$ and subsequently $[Z =]$ $(\bar{Y}, \bar{c}) = ((y, x), x)$. Consequently, (5.23) gives $Z \in f$, as desired. On the other hand, if $\bar{b} = y$ is true, we obtain with (5.38) and (5.27) the equations $\bar{c} = \inf\{y, y\} = y$ and therefore $\bar{c} = y$. This finding in turn implies (together with the case/subcase assumptions) $[\bar{Y} =]$ $(\bar{a}, \bar{b}) = (y, y)$ as well as $[Z =]$ $(\bar{Y}, \bar{c}) = ((y, y), y)$. Finally, (5.24) shows that $Z \in f$ is true once again, so that the nested proofs by cases are complete. We therefore have that the first part of the equivalence in (5.37) holds.

Regarding the second part ('$\Leftarrow$') of that equivalence, we assume conversely that $Z \in f$ holds, so that the disjunction

$$[Z = ((x, x), x) \lor Z = ((x, y), x)] \lor [Z = ((y, x), x) \lor Z = ((y, y), y)] \tag{5.39}$$

follows to be true with (2.243), where rearranged the brackets according to the Associative Law for the disjunction. We now use this disjunction to prove $Z \in \sqcap$ by cases. In the first case that $Z \in ((x,x),x) \vee Z \in ((x,y),x)$ is true, we apply another proof by cases based on that disjunction to establish the desired $Z \in \sqcap$. If $Z = ((x,x),x)$ holds, then (5.33) immediately gives $Z \in \sqcap$ via substitution, and if $Z = ((x,y),x)$ holds, then the desired $Z \in \sqcap$ follows from (5.34). In the second case that $Z = ((y,x),x) \vee Z = ((y,y),y)$ is true, we consider two further subcases based on that disjunction. If $Z = ((y,x),x)$ is true, then we evidently obtain $Z \in \sqcap$ from (5.35), and if $Z = ((y,y),y)$ holds, then we obtain $Z \in \sqcap$ from (5.36). Thus, the proof by cases is complete based on (5.39) is complete, so that we found $Z \in \sqcap$ to be true, which in turn proves the second part of the equivalence in (5.37).

Since Z is arbitrary, we may therefore conclude that the universal sentence (5.37) holds, so that the equation (5.20) follows to be true with the Equality Criterion for sets. As x and y were also arbitrary, we may then further conclude that the proposed sentence holds, as claimed. □

Exercise 5.3. Show for any x, y that the join with respect to the lattice $(\{x,y\}, \{(x,x),(x,y),(y,y)\})$ is given by the quadruple

$$\sqcup = \{((x,x),x),((x,y),y),((y,x),y),((y,y),y)\}. \tag{5.40}$$

Note 5.3. In light of the preceding proposition and exercise, we may write for the lattice $(\{x,y\}, \{(x,x),(x,y),(y,y)\})$ also (including the join and the meet)

$$\begin{aligned}&(\{x,y\},\\ &\ \{((x,x),x),((x,y),y),((y,x),y),((y,y),y)\},\\ &\ \{((x,x),x),((x,y),x),((y,x),x),((y,y),y)\},\\ &\ \{(x,x),(x,y),(y,y)\}).\end{aligned} \tag{5.41}$$

When the set that underlies a given lattice is a set of functions Y^X, we will use 'curly' versions of the previously introduced join and meet symbol. The unique existence of the join and meet on such function sets and their 'pointwise' definitions in terms of the join and meet on the codomain Y are immediate consequences of Proposition 5.2 and of Theorem 3.254.

Corollary 5.5. *For any set X and any lattice $(Y, \sqcup, \sqcap, \leq)$ there exist the binary operations*

$$\curlyvee_{Y^X} : Y^X \times Y^X \to Y^X, \quad (f,g) \mapsto f \curlyvee g = \overset{\preceq}{\sup}\{f,g\}, \tag{5.42}$$

$$\curlywedge_{Y^X} : Y^X \times Y^X \to Y^X, \quad (f,g) \mapsto f \curlywedge g = \overset{\preceq}{\inf}\{f,g\}, \tag{5.43}$$

where the functions $f \curlyvee g : X \to Y$ *and* $f \curlywedge g : X \to Y$ *satisfy*

$$\forall x \, (x \in X \Rightarrow (f \curlyvee g)(x) = f(x) \sqcup g(x)), \tag{5.44}$$

$$\forall x \, (x \in X \Rightarrow (f \curlywedge g)(x) = f(x) \sqcap g(x)). \tag{5.45}$$

Notation 5.3. Thus, we write for a lattice $(Y^X, \preceq)$ also

$$(Y^X, \curlyvee, \curlywedge, \preceq). \tag{5.46}$$

Furthermore, we call $\sup^{\preceq}\{f, g\}$ $(= f \curlyvee g)$ the *pointwise supremum* of $\{f, g\}$, and we call $\inf^{\preceq}\{f, g\}$ $(= f \curlywedge g)$ the *pointwise infimum* of $\{f, g\}$, which we then symbolize also by, respectively,

$$\sup\{f, g\} \text{ pointwise} \tag{5.47}$$

and

$$\inf\{f, g\} \text{ pointwise.} \tag{5.48}$$

We now introduce notations for two more types of binary operations, which we will define explicitly later on.

Notation 5.4. We use for a binary operation on X in the form of an *addition* the symbol $+$, and we write for the function value at any $(a, b) \in X \times X$

$$a + b, \tag{5.49}$$

which we call the *sum* of a and b; here, we call a and b the *terms* or the *summands* of the sum. Similarly, we symbolize a binary operation on X in the form of a *multiplication* by $\cdot$, in which case we write the function value at each $(a, b) \in X \times X$ as

$$a \cdot b \quad \text{ or shorter } \quad ab, \tag{5.50}$$

which we then call the *product* of a and b.

Additions and multiplications (and in fact any kind of binary operation) on sets, in a certain sense, induce additions and multiplications on associated sets of functions.

Theorem 5.6 (Pointwise addition of functions). *The following sentences are true for any sets* X, Y *and for any addition* $+_Y$ *on* Y*.*

a) For any functions $f : X \to Y$ *and* $g : X \to Y$ *there exists a unique function* $h : X \to Y$ *satisfying*

$$\forall x \, (x \in X \Rightarrow h(x) = f(x) +_Y g(x)). \tag{5.51}$$

b) *There exists a unique set* $+_{Y^X}$ *such that an element* Z *is in* $+_{Y^X}$ *iff* Z *is in* $(Y^X \times Y^X) \times Y^X$ *and moreover if there are functions* f, g, h *from* X *to* Y *satisfying (5.51) and* $((f,g),h) = Z$*, i.e. such that*

$$\forall Z\,(Z \in +_{Y^X} \Leftrightarrow [Z \in (Y^X \times Y^X) \times Y^X \wedge \exists f, g, h\,(f, g, h \in Y^X \wedge \forall x\,(x \in X \Rightarrow h(x) = f(x) +_Y g(x)) \wedge ((f,g),h) = Z)]). \qquad (5.52)$$

The set $+_{Y^X}$ *is a binary operation on* Y^X *satisfying*

$$\forall f, g, h\,(f, g, h \in Y^X \Rightarrow [h = f +_{Y^X} g \Leftrightarrow \forall x\,(x \in X \Rightarrow h(x) = f(x) +_Y g(x))]). \qquad (5.53)$$

Proof. We let X, Y and $\cdot_Y$ be arbitrary sets and assume that $\cdot_Y$ is a multiplication on Y. Concerning a), letting f and g be arbitrary functions from X to Y, we apply Function definition by replacement and verify for this purpose

$$\forall x\,(x \in X \Rightarrow \exists! y\,(y = f(x) +_Y g(x))), \qquad (5.54)$$

letting x be arbitrary and assuming $x \in X$ to be true. Evidently then, the initial assumptions $f : X \to Y$ and $g : X \to Y$ yield $f(x) \in Y$ as well as $g(x) \in Y$, so that $(f(x), g(x)) \in Y \times Y$ [$= \mathrm{dom}(+_Y)$] holds by definition of the Cartesian product of two sets. Because of $+_Y : Y \times Y \to Y$, the function value $y = f(x) +_Y g(x)$ exists then uniquely (in Y). Since x was arbitrary, we may therefore conclude that the universal sentence (5.54) is true, which implies now the unique existence of a function h with domain X such that (5.51) is satisfied. We already showed that any function value $[h(x) =]\ y = f(x) +_Y g(x)$ is an element of Y, so that we may take Y as a codomain of h. As X, Y, f, g and $+_Y$ are arbitrary, we may then further conclude that the proposed universal sentence a) holds.

We evidently obtain the stated uniquely existential sentence in b) by means of the Axiom of Specification and the Equality Criterion for sets. Thus, the uniquely specified set $+_{Y^X}$ satisfies (5.52). This sentence shows for any Z that $Z \in +_{Y^X}$ implies in particular $Z \in (Y^X \times Y^X) \times Y^X$, so that the inclusion $Z \subseteq (Y^X \times Y^X) \times Y^X$ holds. To prove that $+_{Y^X}$ is a binary operation on Y^X, i.e. to establish $+_{Y^X} : Y^X \times Y^X \to Y^X$, we may therefore apply the Function Criterion and verify accordingly

$$\forall z\,(z \in Y^X \times Y^X \Rightarrow \exists! h\,(h \in Y^X \wedge (z, h) \in +_{Y^X})). \qquad (5.55)$$

For this purpose, we let z be arbitrary and assume $z \in Y^X \times Y^X$ to be true. Consequently, there are evidently particular elements $\bar{f} \in Y^X$ and

$\bar{g} \in Y^X$ with $(\bar{f}, \bar{g}) = z$. Because of a), there exists then a (unique) function $\bar{h} : X \to Y$ (i.e., a unique element $\bar{h} \in Y^X$) with

$$\forall x\,(x \in X \Rightarrow \bar{h}(x) = \bar{f}(x) +_Y \bar{g}(x)). \tag{5.56}$$

Defining now the ordered triple $\bar{Z} = ((\bar{f}, \bar{g}), \bar{h})$ $[= (z, \bar{h})]$, we thus see that $\bar{f}, \bar{g}, \bar{h} \in Y^X$ and $\bar{Z} \in (Y^X \times Y^X) \times Y^X$ hold; together with (5.56), these findings give $[(z, \bar{h}) =]$ $\bar{Z} \in +_{Y^X}$ with (5.52). Since $\bar{h}$ satisfies both $\bar{h} \in Y^X$ and $(z, \bar{h}) \in +_{Y^X}$, the existential part in (5.55) holds. To establish the uniqueness part, we take arbitrary sets h and h', assume $h, h' \in Y^X$ and $(z, h), (z, h') \in +_{Y^X}$ to be both true, and show that $h = h'$ is implied. Since the former assumption implies that h and h' are both functions from X to Y, we may prove the preceding equation by means of the Equality Criterion for functions, i.e. by verifying

$$\forall x\,(x \in X \Rightarrow h(x) = h'(x)). \tag{5.57}$$

The other assumption $(z, h), (z, h') \in +_{Y^X}$ implies with (5.52) the existence of particular elements $\bar{f}, \bar{g}, \bar{h}$ and $\bar{f}', \bar{g}', \bar{h}'$ in Y^X satisfying

$$\forall x\,(x \in X \Rightarrow \bar{h}(x) = \bar{f}(x) +_Y \bar{g}(x)) \tag{5.58}$$

and $((\bar{f}, \bar{g}), \bar{h}) = (z, h)$, as well as

$$\forall x\,(x \in X \Rightarrow \bar{h}'(x) = \bar{f}'(x) +_Y \bar{g}'(x)) \tag{5.59}$$

and $((\bar{f}', \bar{g}'), \bar{h}') = (z, h')$. Then, the Equality Criterion for ordered pairs yields first the conjunction of $(\bar{f}, \bar{g}) = z$ and $\bar{h} = h$ as well as the conjunction of $(\bar{f}', \bar{g}') = z$ and $\bar{h}' = h'$; thus, substitution gives $(\bar{f}, \bar{g}) = (\bar{f}', \bar{g}')$, so that we obtain (again with the Equality Criterion for ordered pairs) $\bar{f} = \bar{f}'$ as well as $\bar{g} = \bar{g}'$. We are now in a position to verify the universal sentence (5.57), letting x be arbitrary in X, so that the previous two equations, alongside the previously established equations $\bar{h} = h$ and $\bar{h}' = h'$, imply with the Equality Criterion for functions $\bar{f}(x) = \bar{f}'(x)$, $\bar{g}(x) = \bar{g}'(x)$, $\bar{h}(x) = h(x)$ and $\bar{h}'(x) = h'(x)$. We therefore obtain with (5.58) and (5.59) via substitutions the equations

$$h(x) = \bar{h}(x) = \bar{f}(x) +_Y \bar{g}(x) = \bar{f}'(x) +_Y \bar{g}'(x) = \bar{h}'(x) = h'(x).$$

Since x is arbitrary, we may now conclude that the universal sentence (5.57) is true, so that $h = h'$ holds indeed. We thus proved the uniquely existential sentence in (5.55), and as z was arbitrary, we may infer from this the truth also of the universal sentence (5.55). This finding in turn establishes $+_{Y^X}$ as a function from $Y^X \times Y^X$ to Y^X, and thus as a binary operation on Y^X.

It now remains for us to prove that $+_{Y^X}$ satisfies (5.53). To do this, we take arbitrary $f, g, h \in Y^X$ and assume first $h = f +_{Y^X} g$ to be true, which we may write as $((f, g), h) \in +_{Y^X}$. Consequently, the universal sentence

$$\forall x\,(x \in X \Rightarrow h(x) = f(x) +_Y g(x))$$

follows to be true with (5.52). We now conversely assume the preceding universal sentence to be true and define the ordered triple $Z = ((f, g), h)$. Furthermore, because of the assumption $f, g, h \in Y^X$, we evidently obtain $Z \in (Y^X \times Y^X) \times Y^X$ by applying (twice) the definition of the Cartesian product of two sets. Clearly, these findings imply $((f, g), h) \in +_{Y^X}$ with (5.52), which we may write as $h = f +_{Y^X} g$. Thus, the proof of the equivalence in (5.53) is complete, and since f, g, h were arbitrary, we may therefore conclude that $+_{Y^X}$ satisfies indeed (5.53). This completes the proof of b); as X, Y and $+_Y$ were initially arbitrary sets, we may now finally conclude that the theorem holds, as claimed. $\square$

As a first application of the preceding proposition, we consider the addition of matrices.

Exercise 5.4 (Addition of matrices). Show for any positive natural numbers m, n, any set Y and any addition $+_Y$ on Y that the addition $+_{Y^{m \times n}}$ in the sense of (5.52) exists uniquely and satisfies

$$\begin{aligned}&\forall \boldsymbol{A}, \boldsymbol{B}, \boldsymbol{C}\,(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{C} \in Y^{m \times n} \Rightarrow [\boldsymbol{C} = \boldsymbol{A} +_{Y^{m \times n}} \boldsymbol{B} \\ &\quad\Leftrightarrow \forall i, j\,([i \in \{1, \ldots, m\} \wedge j \in \{1, \ldots, n\}] \Rightarrow c_{i,j} = a_{i,j} +_Y b_{i,j})]).\end{aligned} \tag{5.60}$$

(Hint: Use Notation 4.10, Definition 3.4, Definition 4.19, and Exercise 3.4.)

Notation 5.5. The addition of two given matrices can be expressed conveniently by

$$\begin{aligned}\boldsymbol{A} +_{Y^{m \times n}} \boldsymbol{B} &= \begin{bmatrix} a_{1,1} & \cdots & a_{1,n} \\ \vdots & \ddots & \vdots \\ a_{m,1} & \cdots & a_{m,n} \end{bmatrix} +_{Y^{m \times n}} \begin{bmatrix} b_{1,1} & \cdots & b_{1,n} \\ \vdots & \ddots & \vdots \\ b_{m,1} & \cdots & b_{m,n} \end{bmatrix} \\ &= \begin{bmatrix} a_{1,1} +_Y b_{1,1} & \cdots & a_{1,n} +_Y b_{1,n} \\ \vdots & \ddots & \vdots \\ a_{m,1} +_Y b_{m,1} & \cdots & a_{m,n} +_Y b_{m,n} \end{bmatrix}.\end{aligned} \tag{5.61}$$

Multiplications on sets of functions can be established in analogy to additions.

Theorem 5.7 (Pointwise multiplication of functions). *following sentences for any sets X, Y and for any multiplication $\cdot_Y$ on Y.*

a) For any functions $f : X \to Y$ and $g : X \to Y$ there exists a unique function $h : X \to Y$ satisfying

$$\forall x\, (x \in X \Rightarrow h(x) = f(x) \cdot_Y g(x)). \tag{5.62}$$

b) There exists a unique set $\cdot_{Y^X}$ such that an element Z is in $\cdot_{Y^X}$ iff Z is in $(Y^X \times Y^X) \times Y^X$ and moreover if there are functions f, g, h from X to Y satisfying (5.62) and $((f, g), h) = Z$, i.e. such that

$$\forall Z\, (Z \in \cdot_{Y^X} \Leftrightarrow [Z \in (Y^X \times Y^X) \times Y^X \wedge \exists f, g, h\, (f, g, h \in Y^X \wedge \\ \forall x\, (x \in X \Rightarrow h(x) = f(x) \cdot_Y g(x)) \wedge ((f, g), h) = Z)]). \tag{5.63}$$

The set $\cdot_{Y^X}$ is a binary operation on Y^X satisfying

$$\forall f, g, h\, (f, g, h \in Y^X \\ \Rightarrow [h = f \cdot_{Y^X} g \Leftrightarrow \forall x\, (x \in X \Rightarrow h(x) = f(x) \cdot_Y g(x))]). \tag{5.64}$$

Exercise 5.5. Establish the Pointwise multiplication of functions.

Theorem 5.8 (Addition of sets). *The following sentences are true for any set X and for any addition $+$ on X:*

a) For any sets $A \subseteq X$ and $B \subseteq X$ there exists a unique set $A \oplus B$ satisfying

$$\forall s\, (s \in A \oplus B \Leftrightarrow \exists a, b\, (a \in A \wedge b \in B \wedge s = a + b)), \tag{5.65}$$

and this set is a subset of X.

b) There exists a unique function $\bigoplus$ on $\mathcal{P}(X) \times \mathcal{P}(X)$ such that

$$\forall x\, (x \in \mathcal{P}(X) \times \mathcal{P}(X) \Rightarrow \exists A, B\, (A \subseteq X \wedge B \subseteq X \wedge (A, B) = x \\ \wedge \bigoplus(x) = A \oplus B)), \tag{5.66}$$

and this function is a binary operation on $\mathcal{P}(X)$.

Proof. We take an arbitrary set X and an arbitrary addition $+$ on X. Concerning a), we may evidently apply the Axiom of Specification and the Equality Criterion for sets to prove the unique existence of a set $A \oplus B$ such that

$$\forall s\, (s \in A \oplus B \Leftrightarrow [s \in X \wedge \exists a, b\, (a \in A \wedge b \in B \wedge s = a + b)]). \tag{5.67}$$

Letting now s be arbitrary, we see that $s \in A \oplus B$ implies especially the truth of the existential sentence, so that the first part ('$\Rightarrow$') of the equivalence in (5.65) is satisfied. Conversely, that existential sentence implies the truth of $s = \bar{a} + \bar{b}$ for some particular elements $\bar{a} \in A$ and $\bar{b} \in B$. Since $+$ is a binary operation on X, the value s of that addition clearly constitutes an element of X. This finding $s \in X$ implies now in conjunction with the assumed existential sentence, by virtue of (5.67), that $y \in A \oplus B$ holds. This establishes the second part ('$\Leftarrow$') of the equivalence in (5.65), and since s is arbitrary, we may therefore conclude that $A \oplus B$ satisfies indeed (5.65). Since $s \in A \oplus B$ implies $s \in X$ for an arbitrary s, the inclusion $A \oplus B \subseteq X$ follows to be true by definition of a subset. As A and B were arbitrary, we may now conclude that Part a) of the stated theorem holds.

To establish b), we first apply Function definition by replacement and prove

$$\forall x\,(x \in \mathcal{P}(X) \times \mathcal{P}(X) \Rightarrow \exists! y\,(\exists A, B\,(A \subseteq X \;\wedge\; B \subseteq X \;\wedge\; (A,B) = x \\ \wedge\; y = A \oplus B))). \tag{5.68}$$

Letting $x \in \mathcal{P}(X) \times \mathcal{P}(X)$ be arbitrary, there exist then particular sets $\bar{A}, \bar{B} \in \mathcal{P}(X)$ with $(\bar{A}, \bar{B}) = x$ in view of Exercise 3.4. By definition of a power set, $\bar{A}$ and $\bar{B}$ are then both subsets of X. Consequently, the set $\bar{y} = \bar{A} \oplus \bar{B}$ is uniquely specified by a). These findings demonstrate the truth of the existential sentence

$$\exists A, B\,(A \subseteq X \;\wedge\; B \subseteq X \;\wedge\; \bar{y} = A \oplus B),$$

which is satisfied by the specific set $\bar{A} \oplus \bar{B}$, so that the existential sentence with respect to y in (5.68) also holds. Regarding the uniqueness part, we now take arbitrary sets y and y' satisfying the corresponding existential sentences

$$\exists A, B\,(A \subseteq X \;\wedge\; B \subseteq X \;\wedge\; (A,B) = x \;\wedge\; y = A \oplus B),$$
$$\exists A, B\,(A \subseteq X \;\wedge\; B \subseteq X \;\wedge\; (A,B) = x \;\wedge\; y' = A \oplus B).$$

We therefore find $y = \bar{A} \oplus \bar{B}$ and $y' = \bar{A}' \oplus \bar{B}'$ for some particular subsets $\bar{A}, \bar{A}', \bar{B}, \bar{B}'$ of X satisfying $(\bar{A}, \bar{B}) = x = (\bar{A}', \bar{B}')$. The latter equation yields with the Equality Criterion for ordered pairs $\bar{A} = \bar{A}'$ as well as $\bar{B} = \bar{B}'$, so that the previous equation for y becomes after substitutions $y = \bar{A}' \oplus \bar{B}'$ $[= y']$; thus, $y = y'$. Since y and y' were arbitrary, we may therefore conclude that the uniquely existential sentence in (5.66) holds. As x was also arbitrary, we may infer from this the truth of the universal sentence (5.66), and therefore the existence of a unique function $\bigoplus$ on $\mathcal{P}(X) \times \mathcal{P}(X)$ satisfying (5.66). To prove that this function constitutes a binary operation on $\mathcal{P}(X)$, we need to show that this power set is a codomain of the function, i.e., that the inclusion $\mathrm{ran}(\bigoplus) \subseteq \mathcal{P}(X)$ holds. Letting for this purpose $y \in \mathrm{ran}(\bigoplus)$ be arbitrary, it follows by definition of a range that there exists a particular set x with $(x, y) \in \mathrm{ran}(\bigoplus)$. Since $\bigoplus$ is a function, we may write this finding also as $y = \bigoplus(x)$, and we also see in light of the definition of a domain that $x \in \mathcal{P}(X) \times \mathcal{P}(X)$ $[= \mathrm{dom}(\bigoplus)]$ is true. By virtue of (5.66), we then have $(\bar{A}, \bar{B}) = x$ and $[y =]$ $\bigoplus(x) = \bar{A} \oplus \bar{B}$ for particular subsets $\bar{A}$ and $\bar{B}$ of X. Since $\bar{A} \oplus \bar{B}$ is a subset of X, as shown in a), we find $y \subseteq X$ through substitution, and this clearly means that y is an element of the power set of X. As y was arbitrary, we may therefore conclude that the inclusion $\mathrm{ran}(\bigoplus) \subseteq \mathcal{P}(X)$ holds indeed. We thus showed that $\bigoplus$ is a binary operation on $\mathcal{P}(X)$, so that the proof of Part b) is now complete.

As X and $+$ were initially arbitrary, we conclude that the stated theorem is true. □

Exercise 5.6. Establish the truth of the following universal sentence for any set X and any addition $+$ on X:

$$\forall A, B\,([A \subseteq X \;\wedge\; B \subseteq X] \Rightarrow \bigoplus((A, B)) = A \oplus B). \tag{5.69}$$

(Hint: Use (5.66) in connection with the Equality Criterion for ordered pairs.)

Notation 5.6. On the one hand, since $\bigoplus$ is a binary operation, we may write $\bigoplus((A, B)) = A \bigoplus B$. In view of the preceding exercise, we may therefore also write $A \oplus B$ instead of $A \bigoplus B$ for the value of that binary operation.

Exercise 5.7. Show for any set X that there exists a unique function $\circ_X$ on the set X^X of transformations on X such that

$$\forall z\,(z \in X^X \times X^X \Rightarrow \exists g, h\,(g, h \in X^X \wedge (g, h) = x \wedge \circ_X(z) = g \circ h)) \tag{5.70}$$

and that this function constitutes a binary operation on X^X. Establish in addition the truth of

$$\forall g, h\,(g, h \in X^X \Rightarrow g \circ_X h = g \circ h). \tag{5.71}$$

(Hint: Use the fact (3.604).)

Proposition 5.9. *It is true for any set $T(X)$ of invertible transformations on any set X that the restriction*

$$\circ_{T(X)} = \circ_X \restriction T(X) \times T(X) \tag{5.72}$$

of the composition on the set X^X of transformations on X constitutes a restricted binary operation.

Proof. We let X be an arbitrary set and $T(X)$ an arbitrary set of invertible transformations on X. Thus, $T(X)$ is a subset of the set X^X of transformations on X (see Note 3.27). Consequently, the Cartesian product $T(X) \times T(X)$ is a subset of the Cartesian product $X^X \times X^X$ because of Proposition 3.8. Therefore, the restriction (5.72) of $\circ_X : X^X \times X^X \to X^X$ to $T(X) \times T(X)$ is a function from $T(X) \times T(X)$ to X^X due to (3.566). It remains for us to prove that $T(X)$ is also a codomain of that restriction, i.e., that the range of $\circ_{T(X)}$ is a subset of $T(X)$. For this purpose, we apply the definition of a subset and let accordingly $y \in \mathrm{ran}(\circ_{T(X)})$ be arbitrary. By definition of a range, there exists then a particular constant z such that $(z, y) \in \circ_{T(X)}$. Since $\circ_{T(X)}$ is a function with domain $T(X) \times T(X)$, we may on the one hand write $y = \circ_{T(X)}(z)$; on the other hand, we find that z is an element of that domain (by definition). These findings imply now on the one hand $[\circ_{T(X)}(z) =]\ y = \circ_X(z)$ with (3.567). On the other hand, $z \in T(X) \times T(X)$ implies by virtue of Exercise 3.4 that there exist particular elements $g, h \in T(X)$ with $(g, h) = z$. This allows us to write $y = \circ_X((g, h)) = g \circ_X h = g \circ h$ by using the fact that $\circ_X$ is a binary operation satisfying (5.71). Furthermore, $g, h \in T(X)$ yields $g : X \rightleftarrows X$ and $h : X \rightleftarrows X$ by means of (3.685). Due to the Bijectivity of the composition of two bijections (3.672), we obtain now $[y =]\ g \circ h : X \rightleftarrows X$, so that $y \in T(X)$ is clearly true. As y was arbitrary, we may therefore conclude that the range of $\circ_{T(X)}$ is indeed a subset of $T(X)$, i.e., that $T(X)$ is a codomain of the restriction (5.72). This means that this restriction, being a function on $T(X) \times T(X)$, is a binary operation on $T(X)$. Thus, $\circ_{T(X)}$ constitutes a restricted binary operation on $T(X)$, by definition. Since X and $T(X)$ were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Corollary 5.10. *It is true for any finite set X that the restriction*

$$\circ_{\Pi(X)} = \circ_X \restriction \Pi(X) \times \Pi(X) \tag{5.73}$$

of the composition on the set X^X of transformations on X constitutes a restricted binary operation on the set $\Pi(X)$ of permutations of X.

Corollary 5.11. *The composition of two invertible transformations g and h in any set $T(X)$ of invertible transformations on any set X is identical with the value of the binary composition operation on $T(X)$ associated with g and h, that is,*

$$\forall g, h\, (g, h \in T(X) \Rightarrow g \circ_{T(X)} h = g \circ h). \tag{5.74}$$

Proof. We let X be an arbitrary set, $T(X)$ an arbitrary set of invertible transformations on X, g, h arbitrary invertible transformations on X, and

x an arbitrary element of X. We first observe that $g \circ_{T(X)} h$ is an element of $T(X)$ since $\circ_{T(X)}$ is a binary operation on $T(X)$ (see Proposition 5.9). This means that $g \circ_{T(X)} h$ is an invertible transformation on X and thus a (bijective) function on X by definition. Furthermore, $g \circ h$ is also a function on X due to Proposition 3.178, using the fact that the invertible transformations g and h on X are themselves (bijective) functions on X. We now let $x \in X$ be arbitrary and observe the truth of the equations

$$\begin{aligned} g \circ_{T(X)} h(x) &= g \circ_X h \restriction T(X) \times T(X)(x) \\ &= g \circ_X h(x) \\ &= g \circ h(x) \end{aligned}$$

in light of (5.72), (3.567) and (5.71). Since x was arbitrary, we may now infer from the truth of the resulting equation $g \circ_{T(X)} h(x) = g \circ h(x)$ the truth of $g \circ_{T(X)} h = g \circ h$ by virtue of the Equality Criterion for functions. As X, $T(X)$, g and h were also arbitrary, we may therefore conclude that the stated universal sentence holds. □

Note 5.4. Since the set of permutations of a (finite) set X constitutes a set of invertible transformations, we may write in particular

$$\forall g, h \, (g, h \in \Pi(X) \Rightarrow g \circ_{\Pi(X)} h = g \circ h). \tag{5.75}$$

Exercise 5.8. Show for any function $f : X \to Y$ and any set $T_{fi}(X)$ under which f is invariant that the restriction

$$\circ_{T_{fi}(X)} = \circ_X \restriction T_{fi}(X) \times T_{fi}(X) \tag{5.76}$$

of the composition on the set X^X of transformations on X constitutes a restricted binary operation on $T_{fi}(X)$. Establish then the truth of

$$\forall g, h \, (g, h \in T_{fi}(X) \Rightarrow g \circ_{T_{fi}(X)} h = g \circ h). \tag{5.77}$$

(Hint: Proceed in analogy to the proofs of Proposition 5.9 and Corollary 5.11, using Proposition 3.183.)

Definition 5.3 (Translation, scaling). We say for any set X, any element $a \in X$ and

a) any addition $+$ on X that a transformation on X is a *translation* (*on X by a*), symbolically

$$g_{La} : X \to X, \tag{5.78}$$

iff every element of its domain is associated with the sum of x and a, i.e.

$$\forall x \, (x \in X \Rightarrow f(x) = x + a). \tag{5.79}$$

b) any multiplication $\cdot$ on X that a transformation on X is a *scaling* (*on X by a*), symbolically
$$g_{Sa} : X \to X, \tag{5.80}$$
iff every element of its domain is associated with the product of a and x, i.e.
$$\forall x\, (x \in X \Rightarrow f(x) = a \cdot x). \tag{5.81}$$

Exercise 5.9. Show for any set X, any element $a \in X$ and

a) any addition $+$ on X that there exists a unique function g_{La} on X with the definite property (5.79), and that this function is a translation on X by a.

b) any multiplication $\cdot$ on X that there exists a unique function g_{Sa} on X with the definite property (5.81), and that this function is a scaling on X by a.

(Hint: Apply Function definition by replacement and show then that the defined functions constitute transformations on X.)

Note 5.5. For any set X, any addition $+$ and any multiplication $\cdot$ on X, we may evidently apply the Axiom of Specification and the Equality Criterion for sets to prove the unique existence of sets $G_L(X)$ and $G_S(X)$ consisting, respectively, of all translations and all scalings on X, in the sense that
$$\forall f\, (f \in G_L(X) \Leftrightarrow [f \in X^X \wedge \exists a\, (a \in X \wedge \forall x\, (x \in X \Rightarrow f(x) = x + a))]), \tag{5.82}$$
$$\forall f\, (f \in G_S(X) \Leftrightarrow [f \in X^X \wedge \exists a\, (a \in X \wedge \forall x\, (x \in X \Rightarrow f(x) = a \cdot x))]). \tag{5.83}$$

Since $f \in G_L(X)$ and $f \in G_S(X)$ both imply $f \in X^X$ for an arbitrary f, we see in light of the definition of subset that the inclusions $G_L(X) \subseteq X^X$ and $G_S(X) \subseteq X^X$ hold.

Definition 5.4 (Set of translations, set of scalings). For any set X

a) and any addition $+$ on X, we call
$$G_L(X) \tag{5.84}$$
the *set of translations* on X.

b) and any multiplication $\cdot$ on X, we call
$$G_S(X) \tag{5.85}$$
the *set of scalings* on X.

Proposition 5.12. *For any set X and any binary operation $*$ on X it is true that, if there exists an element e in X such that $e*a=a$ and $a*e=a$ hold for any $a\in X$, then e is unique, that is,*

$$\forall X,*\,([*\in X^{X\times X}\ \wedge\ \exists e\,(e\in X\ \wedge\ \forall a\,(a\in X\Rightarrow[e*a=a\ \wedge\ a*e=a]))]$$
$$\Rightarrow\exists!e\,(e\in X\ \wedge\ \forall a\,(a\in X\Rightarrow[e*a=a\ \wedge\ a*e=a]))). \tag{5.86}$$

Proof. We let X and $*$ be arbitrary sets, assume that $*$ is a binary operation on X, and assume moreover that there is a constant, say $\bar{e}$, such that the conjunction of $\bar{e}\in X$ and

$$\forall a\,(a\in X\Rightarrow[\bar{e}*a=a\ \wedge\ a*\bar{e}=a]) \tag{5.87}$$

is true. Let us now apply Method 1.18 to establish the uniquely existential sentence. Since $\bar{e}$ is a particular constant which satisfies the conjunction within the uniquely existential sentence, it only remains for us to verify

$$\forall e'\,([e'\in X\ \wedge\ \forall a\,(a\in X\Rightarrow[e'*a=a\ \wedge\ a*e'=a])]\Rightarrow\bar{e}=e'). \tag{5.88}$$

To prove this universal sentence, we let e' be arbitrary, assume the conjunction of $e'\in X$ and

$$\forall a\,(a\in X\Rightarrow[e'*a=a\ \wedge\ a*e'=a]), \tag{5.89}$$

to be true, and show that $\bar{e}=e'$ is implied. On the one hand, the previously established $\bar{e}\in X$ implies with (5.89)

$$e'*\bar{e}=\bar{e}\ \wedge\ \bar{e}*e'=\bar{e}.$$

On the other hand, the assumed $e'\in X$ implies with (5.87)

$$\bar{e}*e'=e'\ \wedge\ e'*\bar{e}=e'.$$

Thus, the two equations

$$\bar{e}=e'*\bar{e}=e'$$

hold in particular, so that $\bar{e}=e'$ follows indeed to be true. Since e' is arbitrary, we may therefore conclude that the universal sentence (5.88) holds, completing the proof of the uniquely existential sentence in (5.86). This in turn proves the implication in (5.86), and as X and $*$ were initially arbitrary sets, we may finally conclude that the proposed universal sentence is true. □

Definition 5.5 (Identity element, neutral element). For any set X and any binary operation $*$ on X we call the unique element $e\in X$ that satisfies

$$\forall a\,(a\in X\Rightarrow[e*a=a\ \wedge\ a*e=a]) \tag{5.90}$$

the *identity element* or the *neutral element* of X with respect to $*$.

Note 5.6. In view of the Neutrality of identity functions under composition in connection with (5.71), we obtain for any set X from (3.610) the universal sentence

$$\forall f\,(f \in X^X \Rightarrow [\mathrm{id}_X \circ_X f = f \,\wedge\, f \circ_X \mathrm{id}_X = f]), \tag{5.91}$$

which demonstrates that the identity function on X constitutes the identity element of the set of transformations on X with respect to $\circ_X$.

Proposition 5.13. *It is true for any set X, any binary operation $*$ on X and any set $A \subseteq X$ such that the restriction $*_A$ of $*$ to $A \times A$ is a binary operation (on A) that a constant $e \in A$ is the identity element of A with respect to $*_A$ if e is the identity element of X with respect to $*$.*

Proof. We let X be an arbitrary set, $*$ an arbitrary binary operation on X, A an arbitrary subset of X, and e an arbitrary element of A. We now assume that the restriction $*_A = * \restriction A \times A$ is a binary operation on A, and furthermore that e is the identity element of X with respect to $*$. To prove that e is the identity element of A with respect to $*_A$, we establish

$$\forall a\,(a \in A \Rightarrow [e *_A a \,\wedge\, a *_A e = a]). \tag{5.92}$$

Letting $a \in A$ be arbitrary, we find

$$\begin{aligned} e *_A a &= e * a = a, \\ a *_A e &= a * e = a \end{aligned}$$

by means of (5.4) and the assumption that e is the identity element of X with respect to $*$. We thus obtained $e *_A a = a$ and $a *_A e = a$. As a was arbitrary, we may infer from these findings the truth of the universal sentence (5.92), so that e is by definition the identity element of A with respect to $*_A$. As X, $*$, e were initially arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Note 5.7. The facts

- that the set $\mathcal{T}(X)$ of invertible transformations on a set X is a subset of the set X^X of transformations on X (see Note 3.27),
- that the identity function id_X on any set X is an invertible transformation on that set (see Note 3.26) and thus an element of $\mathcal{T}(X)$, and
- that id_X is the identity element of X^X with respect to the binary composition operation $\circ_X$ on X^X (see Note 5.6)

immediately imply with Proposition 5.13 that id_X is also the identity element of $\mathcal{T}(X)$ with respect to the restricted binary composition operation $\circ_{\mathcal{T}(X)}$ on $\mathcal{T}(X)$ established in Proposition 5.9. In view of Proposition 5.13, id_X is then also the identity element of any subset $T(X) \subseteq \mathcal{T}(X)$ containing id_X with respect to the restricted binary operation $\circ_{T(X)}$.

Note 5.8. In particular, when X is any finite set, then id_X is the identity element of the set $\Pi(X)$ of permutations of X with respect to the restricted binary composition operation $\circ_{\Pi(X)}$ on $\Pi(X)$.

Note 5.9. In analogy to Note 5.7, the facts

- that the set $\mathcal{T}_{fi}(X)$ (of invertible transformations on a set X under which a function $f : X \to Y$ is invariant) is included in the set X^X of transformations on X (see Note 3.28),
- that such a function $f : X \to Y$ is invariant under the identity function id_X (see Note 3.22) and thus an element of $\mathcal{T}_{fi}(X)$, and
- that id_X is the identity element of X^X with respect to the binary composition operation $\circ_X$ on X^X

immediately imply with Proposition 5.13 that id_X is also the identity element of $\mathcal{T}_{fi}(X)$ with respect to the restricted binary composition operation $\circ_{\mathcal{T}_{fi}(X)}$ on $\mathcal{T}_{fi}(X)$ established in Exercise 5.8. Consequently, id_X is also the identity element of any subset $T_{fi}(X) \subseteq \mathcal{T}_{fi}(X)$ containing id_X with respect to the restricted binary operation $\circ_{T_{fi}(X)}$ (by Proposition 5.13).

Proposition 5.14. *For any lattice* $(X, \sqcup, \sqcap, \leq)$ *such that the bottom element* $\bot$ *of* X *exists, it is true that* $\bot$ *is the neutral element of* X *with respect to the join* $\sqcup$.

Proof. We let X, $\sqcup$, $\sqcap$ and $\leq$ be arbitrary sets, assume that $(X, \sqcup, \sqcap, \leq)$ is a lattice, and assume also that the least element $\bot$ of X exists. To prove that $\bot$ is the neutral element of X with respect to $\sqcup$, we verify

$$\forall a\,(a \in X \Rightarrow [\bot \sqcup\ a = a \ \wedge\ a \sqcup \bot = a]). \tag{5.93}$$

For this purpose, we take an arbitrary a in X and verify first

$$[\bot \sqcup\ a =]\quad \sup\{\bot, a\} = a \tag{5.94}$$

(where we used (5.5)). Since the least element $\bot$ of X is in particular a lower bound for X, it is true that

$$\forall b\,(b \in X \Rightarrow \bot \leq b).$$

Thus, the assumed $a \in X$ implies $\bot \leq a$, which inequality further implies with Proposition 3.109 that (5.94) is true. We thus proved the first part of the conjunction in (5.93). Regarding the second part, we observe that $\{a, \bot\} = \{\bot, a\}$ holds according to (2.161), so that (5.94) yields via substitution

$$[a \sqcup \bot =] \quad \sup\{a, \bot\} = a,$$

which equations give the desired $a \sqcup \bot = a$. Since a is arbitrary, we may therefore conclude that (5.93) is true, which shows that $\bot$ is indeed the neutral element of X with respect to $\sqcup$. As X, $\sqcup$, $\sqcap$ and $\leq$ were arbitrary, the proposed universal sentence follows to be true. □

Exercise 5.10. Show for any lattice $(X, \sqcup, \sqcap, \leq)$ for which the top element $\top$ of X exists that $\top$ is the neutral element of X with respect to the meet $\sqcap$.

The preceding proposition and exercise apply immediately to the lattice (5.19) because the bottom and the top element of the singleton underlying this lattice exist according to (3.289).

Corollary 5.15. *For any x it is true that x is the neutral element of $\{x\}$ with respect to both the join and the meet of the lattice $(\{x\}, \{(x,x)\})$.*

We may apply Proposition 5.14 also to the lattice (5.41).

Corollary 5.16. *For any x and any y satisfying $x \neq y$ it is true that*

a) x is the neutral element of $\{x, y\}$ with respect to the join and

b) y is the neutral element of $\{x, y\}$ with respect to the meet

of the lattice $(\{x, y\}, \{(x, x), (x, y), (y, y)\})$.

Proof. Letting x and y be arbitrary, (5.26) and the corresponding equation in Exercise 5.3 show that $\inf\{x, y\} = x$ and $\sup\{x, y\} = y$ hold. Then, Exercise 3.52 and Proposition 3.113 yield $\min\{x, y\} = \inf\{x, y\}$ $[= x]$ and $\max\{x, y\} = \sup\{x, y\}$ $[= y]$, so that x is the bottom element and y the top element of $\{x, y\}$. Consequently, x is the neutral element of $\{x, y\}$ with respect to the join and y the neutral element of $\{x, y\}$ with respect to the meet of the given lattice, according to Proposition 5.14 and Exercise 5.10. Since x and y were arbitrary, we may therefore conclude that the corollary is true. □

Proposition 5.17. *For any counting domain $(C, s, 0_C)$ it is true that 0_C is the neutral element for the join $\sqcup_C$ with respect to the lattice $(C, <_C)$.*

Proof. Letting C, s and 0_C be arbitrary such that $(C, s, 0_C)$ is a counting domain, we have in view of Proposition 4.28 that C – together with the standard linear ordering $<_C$ of C – forms the lattice $(C, <_C)$, including the join $\sqcup_C$. Since 0_C is the least element of C due to Proposition 4.36a), it follows with Proposition 5.14 that 0_C is the neutral element of C with respect to $\sqcup_C$. As C, s and 0_C are arbitrary, we may therefore conclude that the proposition holds. □

Corollary 5.18. *It is true that* 0 *is the neutral element for the join* $\sqcup_{\mathbb{N}}$ *with respect to the lattice* $(\mathbb{N}, <_{\mathbb{N}})$.

We now fix common notations for neutral elements with respect to addition and multiplication.

Notation 5.7. We write for the identity element of a set X with respect to an addition $+$ on X also

$$0_X, \tag{5.95}$$

in which case we speak of the *neutral element for addition* or of the *zero element* of X. Similarly, we write for the identity element of a set X with respect to a multiplication $\cdot$ on X

$$1_X, \tag{5.96}$$

and we call this the *neutral element for multiplication* or the *unity element* of X.

Proposition 5.19. *For any sets* X, Y *and any addition* $+_Y$ *such that the zero element* 0_Y *of* Y *exists, it is true that the set* $X \times \{0_Y\}$ *is*

a) a constant function from X *to* Y *with value* 0_Y

b) and furthermore the zero element of Y^X *with respect to the pointwise addition* $+_{Y^X}$ *of functions.*

Proof. Letting X, Y and $+_Y$, assuming the latter set to be an addition on Y, and assuming the zero element 0_Y to exist, we see that the Cartesian product $g_{0_Y} = X \times \{0_Y\}$ is the constant function on X with value 0_Y. Since $0_Y \in Y$ holds by definition of a neutral element, so that $\{0_Y\} \subseteq Y$ follows to be true with (2.184), we may choose Y as a codomain of the constant function g_{0_Y}. We thus proved a). Furthermore, we see that g_{0_Y} is an element of the set Y^X of functions from X to Y. To prove that g_{0_Y} is the zero element of Y^X, we verify

$$\forall f\,(f \in Y^X \Rightarrow [g_{0_Y} +_{Y^X} f = f \,\wedge\, f +_{Y^X} g_{0_Y} = f]), \tag{5.97}$$

letting f be arbitrary and assuming $f \in Y^X$ to hold. Let us observe here in light of (5.53) that the first of the two equations in (5.97) is equivalent to the universal sentence

$$\forall x\,(x \in X \Rightarrow g_{0_Y}(x) +_Y f(x) = f(x)), \tag{5.98}$$

which we now prove by letting x be arbitrary in X. Since $g_{0_Y}(x) = 0_Y$ holds according to (3.534), where 0_Y is the zero element of Y, we obtain the true equation $[g_{0_Y}(x) =]\ 0_Y +_Y f(x) = f(x)$. As x is arbitrary, we may therefore conclude that the universal sentence (5.98) is true, so that the first part $g_{0_Y} +_{Y^X} f = f$ of the conjunction in (5.97) holds. We may now apply exactly the same arguments to establish the second part $f +_{Y^X} g_{0_Y} = f$, by proving the equivalent universal sentence.

$$\forall x\,(x \in X \Rightarrow f(x) +_Y g_{0_Y}(x) = f(x)). \tag{5.99}$$

Letting $x \in X$ be arbitrary, we obtain $f(x) +_Y g_{0_Y}(x) = f(x) +_Y 0_Y = f(x)$, as desired, which is evidently true for any x. Because f is arbitrary, we may therefore infer from these findings the truth of (5.97), which shows that the set $g_{0_Y} = X \times \{0_Y\}$ is the zero element of Y^X. As X, Y and $+_{Y^X}$ were initially arbitrary, we may finally conclude that the proposition is true. □

As a first example, we may use the preceding proposition to obtain the neutral element with respect to the addition of matrices.

Corollary 5.20. *For any positive natural numbers m, n, any set Y and any addition $+_Y$ such that the zero element 0_Y exists, it is true that the Cartesian product*

$$0_{Y^{m\times n}} = (\{1,\ldots,m\} \times \{1,\ldots,n\}) \times \{0_Y\} \tag{5.100}$$

is the zero element of $Y^{m\times n}$ (with respect to the addition of matrices).

Notation 5.8. We symbolize the zero element (5.100) also by

$$\mathbf{0} = \mathbf{0}_{[m\times n]} = \begin{bmatrix} 0_Y & \cdots & 0_Y \\ \vdots & \ddots & \vdots \\ 0_Y & \cdots & 0_Y \end{bmatrix} \tag{5.101}$$

and call it the *zero matrix* (of $Y^{m\times n}$).

Definition 5.6 (Diagonal matrix). We say for any positive natural number n, any set Y and any addition $+_Y$ such that the zero element 0_Y exists that a square $(n \times n)$-matrix $\boldsymbol{A}$ with values in Y is a *diagonal matrix* iff

$$\forall i, j\,([i, j \in \{1,\ldots,n\} \wedge i \neq j] \Rightarrow a_{i,j} = 0_Y). \tag{5.102}$$

Notation 5.9. Any diagonal matrix $\boldsymbol{A}$ of order n evidently takes the form

$$\boldsymbol{A} = \begin{bmatrix} a_{1,1} & \cdots & 0_Y \\ \vdots & \ddots & \vdots \\ 0_Y & \cdots & a_{n,n} \end{bmatrix}. \tag{5.103}$$

Exercise 5.11. Show for any sets X, Y and any multiplication $\cdot_Y$ such that the unity element 1_Y of Y exists that the set $X \times \{1_Y\}$ is

a) a constant function from X to Y with value 1_Y

b) and furthermore the unity element of Y^X with respect to the pointwise multiplication $\cdot_{Y^X}$ of functions.

We will occasionally inspect relationships between two binary operations (on possibly distinct sets) that behave similarly in the following sense.

Definition 5.7 (Isomorphism). For any sets X and Y, for any binary operations $*$ on X and $\odot$ on Y, and for any bijection $f : X \rightleftarrows Y$, we say that f is an *isomorphism* from $(X, *)$ to $(Y, \odot)$, symbolically

$$f : (X, *) \rightleftarrows (Y, \odot), \tag{5.104}$$

if, and only if,

$$\forall a, b\, (a, b \in X \Rightarrow f(a * b) = f(a) \odot f(b)). \tag{5.105}$$

We then say also that $(X, *)$ and $(Y, \odot)$ are *isomorphic* under f.

Proposition 5.21. *It is true for any sets X and Y, any binary operations $*$ on X and $\odot$ on Y, and any isomorphism $f : (X, *) \rightleftarrows (Y, \odot)$ that*

$$\forall u, v\, (u, v \in Y \Rightarrow u \odot v = f(f^{-1}(u) * f^{-1}(v))). \tag{5.106}$$

Proof. We let X, Y, $*$, $\odot$, f, u and v be arbitrary such that $*$ is a binary operation on X, such that $\odot$ is a binary operation on Y, such that f is an isomorphism from $(X, *)$ to $(Y, \odot)$, and such that u, v are elements of Y. This means in particular that f is a bijection from X to Y, which has the bijective inverse $f^{-1} : Y \rightleftarrows X$ (see Theorem 3.212). Consequently, the values $f^{-1}(u)$ and $f^{-1}(v)$ are elements of X, which fact implies

$$\begin{aligned} f(f^{-1}(u) * f^{-1}(v)) &= f(f^{-1}(u)) \odot f(f^{-1}(v)) \\ &= [f \circ f^{-1}](u) \odot [f \circ f^{-1}](v) \\ &= \mathrm{id}_Y(u) \odot \mathrm{id}_Y(v) \\ &= u \odot v \end{aligned}$$

with (5.105), the notation for function compositions, (3.680) and the definition of the identity function. Because X, Y, $*$, $\odot$, f, a and b are all arbitrary, we may infer from the resulting equation $u \odot v = f(f^{-1}(u) * f^{-1}(v))$ the truth of the proposed sentence. $\square$

Exercise 5.12. Show for any sets X and Y, any binary operations $*$ on X and $\odot$ on Y, and any isomorphism $f : (X, *) \rightleftarrows (Y, \odot)$ that

$$\forall a, b\,(a, b \in X \Rightarrow a * b = f^{-1}(f(a) \odot f(b))). \tag{5.107}$$

(Hint: Apply (5.105) and (3.678).)

Note 5.10. According to (5.107), we can operate on the elements of a set X through an operation on an 'isomorphic' set Y. The existence of an isomorphism and its inverse allows one to transform the elements from one of these sets into corresponding elements within the other set.

5.2. Semigroups $(X, *)$ and Semirings $(X, +, \cdot)$

Definition 5.8 (Idempotent binary operation). We say that a binary operation $*$ on a set X is *idempotent* iff

$$\forall a\,(a \in X \Rightarrow a * a = a). \tag{5.108}$$

Proposition 5.22. *It is true for any set X, any binary operation $*$ on X and any set $A \subseteq X$ such that the restriction of $*$ to $A \times A$ is a binary operation (on A) that this restricted binary operation is idempotent if $*$ is idempotent.*

Proof. We let X be an arbitrary set, $*$ an arbitrary binary operation on X, and A an arbitrary subset of X. We now assume that the restriction $*_A = * \upharpoonright A \times A$ is a restricted binary operation (on A), and moreover that $*$ is idempotent. To demonstrate that $*_A$ is idempotent itself, we establish the truth of the universal sentence

$$\forall a\,(a \in A \Rightarrow a *_A a = a). \tag{5.109}$$

Letting a be an arbitrary element of A, we obtain

$$a *_A a = a * a = a$$

by using (5.4) and the assumption that $*$ is idempotent. Thus, we obtain $a *_A a = a$, and since a was arbitrary, we therefore conclude that the universal sentence (5.109) holds. This means by definition that the restricted binary operation $* \upharpoonright A \times A$ is idempotent. As X, $*$ and A were initially arbitrary, we may therefore conclude that the proposition is true. $\square$

Proposition 5.23. *For any lattice $(X, \sqcup, \sqcap, \leq)$ the join $\sqcup$ is an idempotent binary operation.*

Proof. Letting X, $\sqcup$, $\sqcap$ and $\leq$ be arbitrary sets and assuming $(X, \sqcup, \sqcap, \leq)$ to be a lattice, we obtain for an arbitrary $a \in X$ the equation

$$a \sqcup a = \sup\{a, a\}. \tag{5.110}$$

with the definition of the join in $(X, \sqcup, \sqcap, <)$. Since $\{a, a\} = \{a\}$ holds by definition of a singleton, we may now apply substitution to (5.110), with the consequence that

$$a \sqcup a = \sup\{a\} = a, \tag{5.111}$$

where the second equation holds because of Corollary 3.106. The preceding equations give $a \sqcup a = a$, and since a is arbitrary, we may therefore conclude that the binary operation $\sqcup$ satisfies (5.108). As X, $\sqcup$, $\sqcap$ and $\leq$ were also arbitrary, the proposition follows to be true. $\square$

Exercise 5.13. Show for any lattice $(X, \sqcup, \sqcap, \leq)$ that the meet $\sqcap$ is an idempotent binary operation.

Definition 5.9 (Commutative binary operation). We say that a binary operation $*$ on a set X is *commutative* iff

$$\forall a, b\,(a, b \in X \Rightarrow a * b = b * a). \tag{5.112}$$

Exercise 5.14. Show for any set X, any binary operation $*$ on X and any set $A \subseteq X$ such that the restriction of $*$ to $A \times A$ is a binary operation (on A) that this restricted binary operation is commutative if $*$ is commutative. (Hint: Proceed similarly as in the proof of Proposition 5.22.)

Proposition 5.24. *For any lattice $(X, \sqcup, \sqcap, \leq)$ the join $\sqcup$ is a commutative binary operation.*

Proof. Letting X, $\sqcup$, $\sqcap$ and $\leq$ be arbitrary sets and assuming $(X, \sqcup, \sqcap, \leq)$ to be a lattice, we have for arbitrary $a, b \in X$ by definition of $\sqcup$ that

$$a \sqcup b = \sup\{a, b\} \tag{5.113}$$

holds. Then, substitution based on the fact that $\{a, b\}$ and $\{b, a\}$ are identical sets according to (2.161) yields

$$a \sqcup b = \sup\{b, a\} = b \sqcup a, \tag{5.114}$$

where the second equation holds according to the definition of $\sqcup$. These equations give $a \sqcup b = b \sqcup a$, and because a and b are arbitrary, we may infer from this that $\sqcup$ satisfies (5.112). Since X, $\sqcup$, $\sqcap$ and $\leq$ were initially arbitrary sets, we may then further conclude that the proposition holds, as claimed. □

Exercise 5.15. Show for any lattice $(X, \sqcup, \sqcap, \leq)$ that the meet $\sqcap$ is a commutative binary operation.

Proposition 5.25. *For any sets X, Y and any commutative addition $+_Y$ on Y, it is true that the pointwise addition $+_{Y^X}$ of functions in Y^X is also commutative.*

Proof. We take arbitrary sets X, Y and $+_Y$ such that $+_Y$ is a commutative addition on Y; thus, the addition $+_Y$ satisfies

$$\forall y, z\,(y, z \in Y \Rightarrow y +_Y z = z +_Y y). \tag{5.115}$$

To prove that the addition $+_{Y^X}$ is commutative, we show that this addition satisfies

$$\forall f, g\,(f, g \in Y^X \Rightarrow f +_{Y^X} g = g +_{Y^X} f). \tag{5.116}$$

We take arbitrary sets f and g, assuming $f, g \in Y^X$ to be true, and we use the notations $h = f +_{Y^X} g$ as well as $h' = g +_{Y^X} f$, so that the equation in (5.116) to be proven may evidently be written equivalently as $h = h'$. As elements of Y^X, the sums h and h' are both functions from X to Y. Therefore, we may apply the Equality Criterion for functions to establish $h = h'$. For this purpose, we verify

$$\forall x\,(x \in X \Rightarrow h(x) = h'(x)), \tag{5.117}$$

letting $x \in X$ be arbitrary. We then obtain the true equations

$$h(x) = f(x) +_Y g(x) = g(x) +_Y f(x) = h'(x)$$

by applying (5.53) to $h = f +_{Y^X} g$, then the property of commutativity (5.115), and finally (5.53) to $h' = g +_{Y^X} f$. Since x is arbitrary, we may infer from the resulting equation $h(x) = h'(x)$ the truth of the universal sentence (5.117), which gives $h = h'$ and thus $f +_{Y^X} g = g +_{Y^X} f$. As f and g are also arbitrary, we may now further conclude that the universal sentence (5.116) holds, which means that $+_{Y^X}$ is commutative, by definition. Because the sets X, Y and $+_{Y^X}$ were initially arbitrary, we may finally conclude that the proposed sentence is true. □

We can directly apply Proposition 5.25 to matrices.

Corollary 5.26. *It is true for any positive natural numbers* m, n*, any set* Y *and any commutative addition on* Y *that the corresponding addition* $+_{Y^{m \times n}}$ *of matrices is commutative.*

Exercise 5.16. Verify for any sets X, Y and any commutative multiplication $\cdot_Y$ on Y that the pointwise multiplication $\cdot_{Y^X}$ of functions in Y^X is also commutative.

Proposition 5.27. *For any set* X *and any commutative addition* $+$ *on* X*, it is true that the addition* $\bigoplus$ *of sets in* $\mathcal{P}(X)$ *is also commutative.*

Proof. Letting X and $+$ be arbitrary such that $+$ is a commutative addition on X, and letting moreover A and B be arbitrary elements of $\mathcal{P}(X)$, we prove the required equation $A \oplus B = B \oplus A$ by means of the Equality Criterion for sets. Letting for this purpose s be arbitrary and assuming first $s \in A \oplus B$ to be true, it follows by definition of the addition of sets according to (5.65) that there are constants, say $\bar{a}$ and $\bar{b}$, such that

$$\bar{a} \in A \wedge \bar{b} \in B \wedge s = \bar{a} + \bar{b}. \tag{5.118}$$

Since the conjunction of sentences and the addition on X are commutative, we obtain

$$\bar{b} \in B \wedge \bar{a} \in A \wedge s = \bar{b} + \bar{a}, \tag{5.119}$$

which evidently implies $s \in B \oplus A$. Assuming now conversely $s \in B \oplus A$ to be true, we obtain (5.119) and therefore also (5.118), so that $s \in A \oplus B$ follows to be true as well. We thus demonstrated the truth of the equivalence of $s \in A \oplus B$ and $s \in B \oplus A$, in which s is arbitrary, so that the sets $A \oplus B$ and $B \oplus A$ are indeed identical. As A and B were arbitrary elements of X, we may therefore conclude that the binary operation $\bigoplus$ is commutative. Since X and $+$ were initially also arbitrary, we may further conclude that the proposed universal sentence holds. $\square$

Definition 5.10 (Left-distributive & right-distributive & distributive binary operation). We say for any set X and any binary operations $*$ and $\odot$ on X that

(1) $*$ is *left-distributive* over $\odot$ iff

$$\forall a, b, c\, (a, b, c \in X \Rightarrow a * (b \odot c) = (a * b) \odot (a * c)). \tag{5.120}$$

(2) $*$ is *right-distributive* over $\odot$ iff

$$\forall a, b, c\, (a, b, c \in X \Rightarrow (b \odot c) * a = (b * a) \odot (c * a)). \tag{5.121}$$

(3) $*$ is *distributive* over $\odot$ iff $*$ is left- and right-distributive over $\odot$.

Proposition 5.28. *It is true for any set X and any binary operations $*$ and $\odot$ that $*$ is distributive over $\odot$ if $*$ is commutative and left-distributive over $\odot$.*

Proof. Letting X, $*$ and $\odot$ be arbitrary sets such that $*$ and $\odot$ are binary operations on X, and assuming $*$ to be commutative and left-distributive over $\odot$, so that $*$ and $\odot$ satisfy (5.120), we may show that these binary operations satisfy also (5.121). Letting for this purpose a, b and c be arbitrary, we obtain the equations

$$(b \odot c) * a = a * (b \odot c) = (a * b) \odot (a * c) = (b * a) \odot (c * a)$$

using the assumed commutativity of $*$, (5.120), and again the commutativity of $*$ (twice). Since a, b and c are arbitrary, we may therefore conclude that $*$ and $\odot$ satisfy indeed the universal sentence (5.121). Thus, $*$ is not only left-distributive but also right-distributive over $\odot$, and consequently by definition distributive over $\odot$. Here, X, $*$ and $\odot$ were initially arbitrary sets, so that the proposed universal sentence follows to be true. $\square$

Exercise 5.17. Show for any set X and any binary operations $*$ and $\odot$ that $*$ is distributive over $\odot$ if $*$ is commutative and right-distributive over $\odot$.

(Hint: Proceed in analogy to the proof of Proposition 5.28.)

Exercise 5.18. Prove for any set X, any binary operations $*$ and $\odot$ on X and any set $A \subseteq X$ such that the restrictions of $*$ and $\odot$ to $A \times A$ are binary operations (on A) that the restricted binary operation $*_A = * \restriction A \times A$ is left-distributive/right-distributive/distributive over the restricted binary operation $\odot_A = \odot \restriction A \times A$ if $*$ is correspondingly left-distributive/right-distributive/distributive over $\odot$.

(Hint: Proceed in analogy to Exercise 5.14.)

Proposition 5.29. *For any totally ordered lattice $(X, \sqcup, \sqcap, \leq)$ the meet $\sqcap$ is distributive over the join $\sqcup$.*

Proof. We let X, $\sqcup$, $\sqcap$ and $\leq$ be arbitrary such that $\leq$ is a total ordering of X and such that $(X, \sqcup, \sqcap, <)$ is a lattice. We begin with the verification that $\sqcap$ is left-distributive over $\sqcup$. For this purpose, we let $a, b, c \in X$ be arbitrary and show that this implies

$$a \sqcap (b \sqcup c) = (a \sqcap b) \sqcup (a \sqcap c), \tag{5.122}$$

which we may also write as

$$\inf\{a, \sup\{b, c\}\} = \sup\{\inf\{a, b\}, \inf\{a, c\}\} \tag{5.123}$$

by definition of the join and of the meet. Since $\leq$ is total, the three disjunctions

$$a \leq b \vee b \leq a \tag{5.124}$$
$$a \leq c \vee c \leq a \tag{5.125}$$
$$b \leq c \vee c \leq b \tag{5.126}$$

are true, which we now use to establish the preceding equation via nested proofs by cases.

We first consider the disjunction (5.124) and begin with first the case $a \leq b$, which implies

$$\inf\{a, b\} = a \tag{5.127}$$

with Proposition 3.109. We now consider the second disjunction (5.125), assuming first $a \leq c$ to be true, which yields (again with Proposition 3.109)

$$\inf\{a, c\} = a. \tag{5.128}$$

Let us now observe the truth of the equations

$$\sup\{a, a\} = \sup\{a\} = a \tag{5.129}$$

in light of the equations (5.110) and (5.111). Due to (5.127) and (5.128), we may apply substitutions and rewrite (5.129) as

$$\sup\{\inf\{a,b\},\inf\{a,c\}\} = a. \tag{5.130}$$

Next, we use the third true disjunction (5.126) to prove the proposed equation. On the one hand, if $b \leq c$ holds, then we evidently obtain

$$\sup\{b,c\} = c, \tag{5.131}$$

so that (5.128) becomes after substitution

$$\inf\{a,\sup\{b,c\}\} = a. \tag{5.132}$$

Because of the true equation (5.130), we may now apply substitution and write the preceding equation (5.132) as (5.123), which thus holds in the cases of $a \leq b$, $a \leq c$ and $b \leq c$. On the other hand, if the second part $c \leq b$ of the disjunction (5.126) holds, then

$$\sup\{b,c\} = b, \tag{5.133}$$

evidently follows to be true so that we may now rewrite (5.127) as (5.132). Consequently, the true equations (5.132) and (5.130) give the desired equation (5.123) also for the cases $a \leq b$, $a \leq c$ and $c \leq b$. We now consider the case that the second part $c \leq a$ of the disjunction (5.125) is true, which evidently implies

$$\inf\{a,c\} = c \tag{5.134}$$

and

$$\sup\{a,c\} = a. \tag{5.135}$$

Applying now substitutions based on (5.127) and (5.134), we may write (5.135) as

$$\sup\{\inf\{a,b\},\inf\{a,c\}\} = a. \tag{5.136}$$

Now, since $c \leq a$ and $a \leq b$ are currently both true, it follows with the transitivity of the total ordering $\leq$ that $c \leq b$ also holds. Then, we obtain again (5.133), so that (5.127) becomes (5.132). Thus, the latter implies together with (5.136) the desired equation for $c \leq a$, so that the proof of (5.123) for the first case $a \leq b$ is complete.

In the second case $b \leq a$, we evidently obtain

$$\inf\{a,b\} = b \tag{5.137}$$

instead of (5.127). Considering now the second true disjunction (5.125) again, we first assume that $a \leq c$ holds, so that (5.128) follows to be true.

Furthermore, the transitivity of $\leq$ allows to infer from the truth of $b \leq a$ and $a \leq c$ the truth of $b \leq c$, which inequality in turn implies (5.131). Substitution based on (5.131) allows us then to write (5.128) as (5.132). Moreover, the case assumption $b \leq a$ clearly implies

$$\sup\{b, a\} = a, \tag{5.138}$$

which equation we may write in view of the true (5.137) and (5.128) as (5.136). Therefore, we may combine by means of substitution (5.132) and (5.136) to obtain (5.123), as desired.

We now assume that the second part $c \leq a$ of the disjunction (5.125) holds, which gives (5.134). To complete the proof, we use once again the third true disjunction (5.126) and assume first $b \leq c$ to be true, which yields (5.131). We may now write the latter as

$$\sup\{\inf\{a, b\}, \inf\{a, c\}\} = c \tag{5.139}$$

using (5.137) and (5.134). In addition, we may write (5.134) as

$$\inf\{a, \sup\{b, c\}\} = c \tag{5.140}$$

by means of (5.131). Then, the preceding equation yields the desired (5.123) via substitution based on (5.139). Finally, we assume that $c \leq b$ holds, which implies (5.133), so that we may write (5.137) as

$$\inf\{a, \sup\{b, c\}\} = b. \tag{5.141}$$

Performing now substitutions based on (5.137) and (5.134), we may write instead of (5.133)

$$\sup\{\inf\{a, b\}, \inf\{a, c\}\} = b, \tag{5.142}$$

and therefore (5.141) may be written as (5.123), which equation thus holds both for $b \leq c$ and for $c \leq b$. This completes the proof for the second (sub)case $c \leq a$ and thus the proof for the second case $b \leq a$. Consequently, we may infer from these findings that $\sqcup$ and $\sqcap$ satisfy the implication in (5.120). Since a, b and c are arbitrary, we may therefore conclude that the universal sentence (5.120) holds, so that $\sqcap$ is indeed left-distributive over $\sqcup$. By virtue of Proposition 5.28, $\sqcap$ is then also distributive over $\sqcup$. As X, $\sqcup$, $\sqcap$ and $<$ were initially arbitrary sets, we may then further conclude that the proposition holds, as claimed. □

Exercise 5.19. Show for any totally ordered lattice $(X, \sqcup, \sqcap, \leq)$ that the join $\sqcup$ is distributive over the meet $\sqcap$.

(Hint: Apply (1.37) to switch the two parts in each of the disjunctions (5.124) – (5.126).)

Proposition 5.30. *For any sets X, Y, for any addition $+_Y$ on Y and for any multiplication $\cdot_Y$ on Y which is left-distributive over $+_Y$, it is true that the pointwise multiplication $\cdot_{Y^X}$ of functions in Y^X is left-distributive over the pointwise addition $+_{Y^X}$.*

Proof. We let X, Y, $+_Y$ and $\cdot_Y$ be arbitrary such that $+_Y$ is an addition on Y and such that $\cdot_Y$ is a multiplication on Y which is left-distributive over $+_Y$. To prove that the multiplication $\cdot_{Y^X}$ on Y^X is left-distributive over the addition $+_{Y^X}$ on Y^X, we verify

$$\forall e, f, g\,(e, f, g \in Y^X \Rightarrow e \cdot_{Y^X} (f +_{Y^X} g) = (e \cdot_{Y^X} f) +_{Y^X} (e \cdot_{Y^X} g)). \quad (5.143)$$

Letting e, f, g be arbitrary in Y^X and x be arbitrary in X, we prove the stated equation via the Equality Criterion for functions. To do this, we take an arbitrary x and assume $x \in X$ to be true. We then obtain the equations

$$\begin{aligned}
[e \cdot_{Y^X} (f +_{Y^X} g)](x) &= e(x) \cdot_Y (f +_{Y^X} g)(x) \\
&= e(x) \cdot_Y (f(x) +_Y g(x)) \\
&= (e(x) \cdot_Y f(x)) +_Y (e(x) \cdot_Y g(x)) \\
&= (e \cdot_{Y^X} f)(x) +_Y (e \cdot_{Y^X} g)(x) \\
&= [(e \cdot_{Y^X} f) +_{Y^X} (e \cdot_{Y^X} g)](x)
\end{aligned}$$

by applying (5.64), (5.53), the left-distributivity of $\cdot_Y$ over $+_Y$, again (5.64), and finally again (5.53). Because x is arbitrary, we may therefore conclude that the functions $[e \cdot_{Y^X} (f +_{Y^X} g)]$ and $[(e \cdot_{Y^X} f) +_{Y^X} (e \cdot_{Y^X} g)]$ are identical. Since e, f and g are arbitrary, we may further conclude that (5.143) holds, so that $\cdot_{Y^X}$ is indeed left-distributive over $+_{Y^X}$. Finally, as X, Y, $+_Y$ and $\cdot_Y$ were also arbitrary, the proposed universal sentence follows to be true. □

Exercise 5.20. Prove for any sets X, Y, for any addition $+_Y$ on Y and for any multiplication $\cdot_Y$ on Y which is right-distributive over $+_Y$ that the pointwise multiplication $\cdot_{Y^X}$ of functions in Y^X is right-distributive over the pointwise addition $+_{Y^X}$.

The following property allows us to change the order of evaluating the operation for three elements successively.

Definition 5.11 (Associative binary operation, semigroup, commutative/Abelian semigroup). We say for any set X and any binary operation $*$ on X that

1. $*$ is *associative* iff

$$\forall a,b,c\,(a,b,c\in X\Rightarrow (a*b)*c=a*(b*c)). \tag{5.144}$$

2. the ordered pair

$$(X,*) \tag{5.145}$$

is a *semigroup* iff $*$ is associative.

Furthermore, we say that a semigroup $(X,*)$ is *commutative* or *Abelian* iff $*$ is commutative.

Proposition 5.31. *It is true for any semigroup* $(X,+)$ *that the restriction*

$$\circ_{G_L(X)}=\circ_X\restriction G_L(X)\times G_L(X) \tag{5.146}$$

of the composition on the set X^X *of transformations on* X *constitutes a restricted binary operation on the set* $G_L(X)$ *of translations on* X.

Proof. We let X be an arbitrary and $+$ an arbitrary addition on X such that $(X,+)$ is a semigroup. As mentioned in Note 5.5, the set $G_L(X)$ of translations on X is a subset of the set X^X of transformations on X. Therefore, the Cartesian product $X^X\times X^X$ is included in the Cartesian product $G_L(X)\times G_L(X)$ due to Proposition 3.8. Consequently, the restriction (5.146) of $\circ_X : X^X\times X^X\to X^X$ to $G_L(X)\times G_L(X)$ is a function from $G_L(X)\times G_L(X)$ to X^X due to (3.566). It remains for us to prove that $G_L(X)$ is also a codomain of that restriction, i.e., that the range of $\circ_{G_L(X)}$ is a subset of $G_L(X)$. For this purpose, we apply the definition of a subset and let accordingly $y\in\operatorname{ran}(\circ_{G_L(X)})$ be arbitrary. By definition of a range, there exists then a particular constant z such that $(z,y)\in\circ_{G_L(X)}$. Since $\circ_{G_L(X)}$ is a function with domain $G_L(X)\times G_L(X)$, we may on the one hand write $y=\circ_{G_L(X)}(z)$; on the other hand, we find that z is an element of that domain (by definition). These findings imply now on the one hand $[\circ_{G_L(X)}(z)\ =]\ y=\circ_X(z)$ with (3.567). On the other hand, $z\in G_L(X)\times G_L(X)$ implies by virtue of Exercise 3.4 that there exist particular elements $g,h\in G_L(X)$ with $(g,h)=z$. This allows us to write

$$y=\circ_X((g,h))=g\circ_X h=g\circ h \tag{5.147}$$

by using the fact that $\circ_X$ is a binary operation satisfying (5.71). Furthermore, the translations $g,h\in G_L(X)$ satisfy

$$\forall x\,(x\in X\Rightarrow g(x)=x+\bar{a}), \tag{5.148}$$
$$\forall x\,(x\in X\Rightarrow h(x)=x+\bar{b}) \tag{5.149}$$

for some particular elements $\bar{a}, \bar{b} \in X$. We now prove

$$\forall x \, (x \in X \Rightarrow (g \circ h)(x) = x + (\bar{a} + \bar{b})). \tag{5.150}$$

Letting $x \in X$ be arbitrary, we obtain

$$(g \circ h)(x) = g(h(x)) = g(x + \bar{b}) = (x + \bar{b}) + \bar{a} = x + (\bar{b} + \bar{a})$$

using the notation for the composition of functions, (5.149), (5.148) with the fact that $x + \bar{b} \in X$ since $+$ is a binary operation on X, and finally the associativity of the addition $+$ on X. Since x is an arbitrary element of X, we may therefore conclude that the universal sentence (5.150) is indeed true. Denoting $\bar{c} = \bar{b} + \bar{a}$, which sum is evidently in X, we now see that the existential sentence

$$\exists c \, (c \in X \ \wedge \ \forall x \, (x \in X \Rightarrow (g \circ h)(x) = x + c)$$

is true. We also see in light of the previous equations (5.147) that $g \circ h$ is a value of the binary operation $\circ_X$ on X^X and therefore an element of X^X. These two findings imply now $[y =] \; g \circ h \in G_L(X)$ with (5.82), thus $y \in G_L(X)$. As y was arbitrary, we may therefore conclude that the range of $\circ_{G_L(X)}$ is indeed a subset of $G_L(X)$, i.e., that $G_L(X)$ is a codomain of the restriction (5.146). This means that this restriction with domain $G_L(X) \times G_L(X)$ is a binary operation on $G_L(X)$. Thus, $\circ_{G_L(X)}$ constitutes a restricted binary operation on $G_L(X)$, by definition. □

Exercise 5.21. Show for any semigroup $(X, \cdot)$ that the restriction

$$\circ_{G_S(X)} = \circ_X \upharpoonright G_S(X) \times G_S(X) \tag{5.151}$$

of the composition on the set X^X of transformations on X constitutes a restricted binary operation on the set $G_S(X)$ of scalings on X.

(Hint: Proceed as in the proof of Proposition 5.31.)

Exercise 5.22. Show that the composition of two translations/scalings g and h is identical with the value of the binary composition operation on the set of translations/scalings associated with g and h, that is,

$$\forall g, h \, (g, h \in G_L(X) \Rightarrow g \circ_{G_L(X)} h = g \circ h), \tag{5.152}$$

$$\forall g, h \, (g, h \in G_S(X) \Rightarrow g \circ_{G_S(X)} h = g \circ h). \tag{5.153}$$

(Hint: Recall the proof of Corollary 5.11.)

Proposition 5.32. *For any semigroup* $(X, +)$ *such that the neutral element* 0 *of* X *with respect to the addition exists, it is true that the identity function on any set* X *constitutes the neutral element of the set* $G_L(X)$ *of translations on* X *with respect to the (restricted) binary composition operation* $\circ_{G_L(X)}$.

Proof. We let $(X, +)$ be an arbitrary set, assuming $(X, +)$ to be a semigroup and assuming the neutral element 0 of X with respect to the addition to exist. Thus, 0 is an element of X by definition of a neutral element. We may now prove that the identity function on X satisfies

$$\forall x\,(x \in X \Rightarrow \mathrm{id}_X(x) = x + 0).$$

Letting $x \in X$ be arbitrary, we indeed obtain the equations

$$\mathrm{id}_X(x) = x = x + 0$$

using the definition of an identity function and the definition of a neutral element. Since x was arbitrary, we may therefore conclude that the preceding universal sentence is true, and this finding implies that id_X is a translation on X by 0 (symbolically: g_{L0}) and thus itself an element of $G_L(X)$. Then, as $G_L(X)$ is a subset of X^X (see Note 5.5) and as id_X is the neutral element of X^X with respect to the binary composition operation $\circ_X$ on X^X (see Note 5.6), we may apply Proposition 5.13 to infer that id_X is also the neutral element of $G_L(X)$ with respect to the restricted binary composition operation $\circ_{G_L(X)}$ on $G_L(X)$, given by (5.146). Since $(X, +)$ is arbitrary, we may therefore conclude that the proposed universal sentence holds. □

Exercise 5.23. Prove for any semigroup $(X, \cdot)$ such that the neutral element 1 of X with respect to the multiplication exists that the identity function on any set X constitutes the neutral element of the set $G_S(X)$ of scalings on X with respect to the (restricted) binary composition operation $\circ_{G_S(X)}$.
(Hint: Show that id_X is a scaling on X by 1.)

Note 5.11. Recalling the Associative Law for function composition and (5.71), we obtain for any set X from (3.613), after some relabeling, the universal sentence

$$\forall f, g, h\,(f, g, h \in X^X \Rightarrow [f \circ_X g] \circ_X h = f \circ_X [g \circ_X h]), \tag{5.154}$$

which shows that the binary operation of composition on the set of transformations on X is associative. Thus, the ordered pair

$$(X^X, \circ_X) \tag{5.155}$$

constitutes a semigroup.

Exercise 5.24. Demonstrate for any set X, any binary operation $*$ on X and any set $A \subseteq X$ such that the restriction of $*$ to $A \times A$ is a binary operation (on A) that the restricted binary operation $*_A = * \upharpoonright A \times A$ is associative if $*$ is associative.

(Hint: Proceed in analogy to Exercise 5.14.)

Note 5.12. The Exercises 5.14 and (5.24) show that every (commutative) semigroup $(X, *)$ gives rise to a corresponding (commutative) semigroup

$$(X, *_A) \tag{5.156}$$

if the restriction $*_A$ of $*$ to $A \times A$ with $A \subseteq X$ is a binary operation on A.

Note 5.13. For any set X, the semigroup (5.155) in particular gives rise to

- the semigroup
$$(T(X), \circ) = (T(X), \circ_{T(X)}) \tag{5.157}$$
for any set $T(X)$ of invertible transformations on X, in particular to
- the semigroup
$$(\Pi(X), \circ) = (\Pi(X), \circ_{\Pi(X)}) \tag{5.158}$$
of permutations on X in case of a finite set X,
- the semigroup
$$(T_{fi}(X), \circ) = (T_{fi}(X), \circ_{T_{fi}(X)}), \tag{5.159}$$
for any set $T_{fi}(X)$ of invertible transformations on X under which a function $f : X \to Y$ is invariant, as well as to
- the semigroups
$$(G_L(X), \circ) = (G_L(X), \circ_{G_L(X)}), \tag{5.160}$$
$$(G_S(X), \circ) = (G_S(X), \circ_{G_S(X)}) \tag{5.161}$$
of translations and scalings on X.

Proposition 5.33. *For any lattice* $(X, \sqcup, \sqcap, \leq)$ *it is true that* $(X, \sqcup)$ *is a commutative semigroup.*

Proof. We let X, $\sqcup$, $\sqcap$ and $\leq$ be arbitrary such that $(X, \sqcup, \sqcap, \leq)$ is a lattice and let a, b, c be arbitrary elements of X. On the one hand, we obtain

$$(a \sqcup b) \sqcup c = \sup\{a, b\} \sqcup c = \sup\{\sup\{a, b\}, c\} = \sup\{a, b, c\}. \tag{5.162}$$

with the definition of the join (applied twice) and with Theorem 3.108. On the other hand, the equations

$$a \sqcup (b \sqcup c) = (b \sqcup c) \sqcup a = \sup\{\sup\{b, c\}, a\} = \sup\{b, c, a\} \tag{5.163}$$

are true in view of Proposition 5.24, the definition of the join, and Theorem 3.108. As the sets $\{b, c, a\}$ and $\{a, b, c\}$ are equal according to (2.232), we may now apply substitution to (5.163) to obtain

$$a \sqcup (b \sqcup c) = \sup\{a, b, c\}. \tag{5.164}$$

Finally, we arrive at the desired equation $(a \sqcup b) \sqcup c = a \sqcup (b \sqcup c)$ by combining (5.162) and (5.164). Since a, b, c are arbitrary, we may therefore conclude that $\sqcup$ satisfies (5.144) and is thus associative. Since $\sqcup$ is also commutative according to Proposition 5.24, we have that the ordered pair $(X, \sqcup)$ is a commutative semigroup by definition. As X, $\sqcup$, $\sqcap$ and $\leq$ were arbitrary, we may now conclude that the proposition is true. □

Exercise 5.25. Show for any lattice $(X, \sqcup, \sqcap, \leq)$ that $(X, \sqcap)$ is a commutative semigroup.

Notation 5.10. In light of the uniqueness of the evaluation of an associative binary operation for any three elements, we will oftentimes omit the brackets in such situations and write

$$a * b * c \tag{5.165}$$

instead of $(a * b) * c$ or $a * (b * c)$.

Proposition 5.34. *For any sets* X, Y *and any associative addition* $+_Y$ *on* Y*, it is true that the pointwise addition* $+_{Y^X}$ *of functions in* Y^X *is also associative.*

Proof. We let X, Y and $+_Y$ be arbitrary such that $+_Y$ is an associative addition on Y. To prove that $+_{Y^X}$ is associative, we verify

$$\forall e, f, g\, (e, f, g \in Y^X \Rightarrow (e +_{Y^X} f) +_{Y^X} g = e +_{Y^X} (f +_{Y^X} g)). \tag{5.166}$$

Letting e, f, g be arbitrary in Y^X and x be arbitrary in X, we observe the truth of the equations

$$\begin{aligned}
[(e +_{Y^X} f) +_{Y^X} g](x) &= (e +_{Y^X} f)(x) +_Y g(x) \\
&= (e(x) +_Y f(x)) +_Y g(x) \\
&= e(x) +_Y (f(x) +_Y g(x)) \\
&= e(x) +_Y (f +_{Y^X} g)(x) \\
&= [e +_{Y^X} (f +_{Y^X} g)](x)
\end{aligned}$$

in light of (5.53) and the associativity of $+_Y$. As x is arbitrary, we then obtain the desired equation in (5.166) with the Equality Criterion for functions. Since e, f and g are arbitrary as well, we may conclude that $+_{Y^X}$ is associative. This finding follows now to be true for any X, Y and $+_Y$, because these sets were initially arbitrary. □

Corollary 5.35. *It is true for any positive natural numbers m, n, any set Y and any associative addition on Y that the corresponding addition $+_{Y^{m\times n}}$ of matrices is associative.*

Exercise 5.26. Prove for any sets X, Y and any associative multiplication $\cdot_Y$ on Y that the pointwise multiplication $\cdot_{Y^X}$ of functions in Y^X is also associative.

Note 5.14. Any (commutative) semigroup $(Y, +_Y)$ or $(Y, \cdot_Y)$ induces for any set X a corresponding (commutative) semigroup $(Y^X, +_{Y^X})$ or $(Y^X, \cdot_{Y^X})$ involving the pointwise addition/multiplication of functions in Y^X. For instance, any (commutative) semigroup $(Y, +_Y)$ and any $m, n \in \mathbb{N}_+$ give rise to the (commutative) semigroup $(Y^{m\times n}, +_{Y^{m\times n}})$ with respect to the addition of m-by-n matrices with values in Y.

Proposition 5.36. *For any set X and any associative addition $+$ on X, it is true that the addition $\bigoplus$ of sets in $\mathcal{P}(X)$ is also associative.*

Proof. We let X be an arbitrary set and $+$ an arbitrary associative addition on X. Next, we take arbitrary sets A, B and C in $\mathcal{P}(X)$ and demonstrate the truth of the equation $(A \oplus B) \oplus C = A \oplus (B \oplus C)$. For this purpose, we apply the Equality Criterion for sets, letting s be arbitrary and assuming first $s \in (A \oplus B) \oplus C$ to hold. According to the definition of the addition of sets in (5.65), we then have $s = \bar{f} + \bar{c}$ for some particular constants $\bar{f} \in A \oplus B$ and $\bar{c} \in C$. Here, $\bar{f} \in A \oplus B$ implies the existence of particular constants $\bar{a} \in A$ and $\bar{b} \in B$ with $\bar{f} = \bar{a} + \bar{b}$. Consequently, the previous equation for s becomes $s = (\bar{a} + \bar{b}) + \bar{c}$ after substitution. Since we assumed the addition on X to be associative, $(\bar{a} + \bar{b}) + \bar{c} = \bar{a} + (\bar{b} + \bar{c})$ holds, so that another substitution in the preceding equation for s gives us $s = \bar{a} + (\bar{b} + \bar{c})$. Here, the sum $\bar{g} = \bar{b} + \bar{c}$ is evidently an element of $B \oplus C$, and therefore $s = \bar{a} + \bar{g}$ an element of $A \oplus (B \oplus C)$, as desired. The converse assumption $s \in A \oplus (B \oplus C)$ yields $s = a^* + g^*$ for particular elements $a^* \in A$ and $g^* \in B \oplus C$, where the latter gives us $g^* = b^* + c^*$ for particular elements $b^* \in B$ and $c^* \in C$. We therefore find evidently $s = a^* + (b^* + c^*) = (a^* + b^*) + c^*$. Defining here $f^* = a^* + b^*$, we obtain $f^* \in A \oplus B$, with the consequence that $s = f^* + c^*$ is in the set $(A \oplus B) \oplus C$. We thus demonstrated that $s \in A \oplus (B \oplus C)$ and $s \in (A \oplus B) \oplus C$ are equivalent, where s is arbitrary, so that the sets $A \oplus (B \oplus C)$ and $(A \oplus B) \oplus C$ are identical. As A, B and C were arbitrary, it follows that the binary operation $\bigoplus$ is associative, by definition. Initially, the sets X and $+$ were also arbitrary, so that we may further conclude that the proposition holds. $\square$

In analogy to the formation of a semigroup we may combine a set with two binary operations to form the following kind of ordered triple.

Definition 5.12 (Semiring, commutative/Abelian semiring). For any set X, any addition $+$ on X and any multiplication $\cdot$ on X we say that the ordered triple

$$(X, +, \cdot) \tag{5.167}$$

is a *semiring* iff

1. $(X, +)$ is a commutative semigroup,

2. $(X, \cdot)$ is a semigroup and

3. the multiplication $\cdot$ is distributive over the addition $+$.

Moreover, we say that a semiring $(X, +, \cdot)$ is *commutative* or *Abelian* iff the multiplication $\cdot$ is commutative.

Notation 5.11*.* We also write $a \cdot b + c$ instead of $(a \cdot b) + c$ in view of the widely used convention that a multiplication is evaluated before an addition.

Note 5.15*.* According to Note 5.12 and Exercise 5.18, every (commutative) semiring $(X, +, -)$ induces a corresponding (commutative) semiring

$$(X, +_A, \cdot_A) \tag{5.168}$$

if the restrictions $+_A : + \restriction A \times A$ and $\cdot_A : \cdot \restriction A \times A$ with $A \subseteq X$ are binary operations on A.

We may apply Proposition 5.33, Exercise 5.25 and Proposition 5.29 in connection with Notation 5.4 to obtain the following first example of a semiring.

Corollary 5.37. *For any totally ordered lattice $(X, \leq)$ it is true that, if we view the join $\sqcup$ as an addition $(+)$ and the meet $\sqcap$ as a multiplication $(\cdot)$, then the ordered triple $(X, +, \cdot)$ constitutes a commutative semiring.*

Let us now apply the preceding corollary to the lattices (5.19) and (5.41).

Corollary 5.38. *For any x and any y it is true that the ordered triple*

$$(\{x\}, \{((x, x), x)\}, \{((x, x), x)\}) \tag{5.169}$$

and

$$\begin{aligned}&(\{x,y\},\\&\{((x,x),x),((x,y),y),((y,x),y),((y,y),y)\},\\&\{((x,x),x),((x,y),x),((y,x),x),((y,y),y)\})\end{aligned} \tag{5.170}$$

are commutative semirings.

Note 5.16. Since we established in Corollary 5.37 the join $\sqcup$ as the addition $(+)$ and the meet $\sqcap$ as the multiplication $(\cdot)$ in the semiring based on a totally ordered lattice $(X,\leq)$, we may view the neutral element $\perp$ with respect to the join as the zero element 0_X and the neutral element $\top$ with respect to the meet as the unity element 1_X.

The next corollary summarizes the findings of Proposition 5.25, Exercise 5.16 Proposition 5.34, Exercise 5.26, Proposition 5.30, and Exercise 5.20.

Corollary 5.39. *For any set X and any semiring $(Y,+_Y,\cdot_Y)$, it is true that the ordered triple $(Y^X,+_{Y^X},\cdot_{Y^X})$ containing the pointwise addition and multiplication of functions in Y^X constitutes a semiring as well. If a semiring $(Y,+_Y,\cdot_Y)$ is commutative, then the semiring $(Y^X,+_{Y^X},\cdot_{Y^X})$ is commutative, too.*

Definition 5.13 (Semiring of functions from X to Y). For any set X and any semiring $(Y,+_Y,\cdot_Y)$, we call the ordered triple

$$(Y^X,+_{Y^X},\cdot_{Y^X}) \tag{5.171}$$

(containing the pointwise addition and multiplication of functions in Y^X) the *semiring of functions from X to Y*.

Definition 5.14 (Trivial semiring, nontrivial semiring). We say that a semiring $(X,+,\cdot)$ is *trivial* iff $X=\{0_X\}$, and we say that a semiring $(X,+,\cdot)$ is *nontrivial* iff $X\neq\{0_X\}$.

Taking the semiring (5.169) and recalling from Corollary 5.15 that the singleton set has a neutral element with respect to the join/addition, which we may denote by 0_X according to Notation 5.7, we have an example of a trivial semiring.

Corollary 5.40. *For any x the semiring $(\{x\},\{((x,x),x)\},\{((x,x),x)\})$ is trivial.*

By contrast, the semiring (5.170) turns out to be nontrivial in case the underlying set is a genuine pair.

Corollary 5.41. *For any x and any y satisfying $x \neq y$ it is true that the semiring $(\{x, y\}, \sqcup, \sqcap)$ in (5.170) is nontrivial.*

Proof. Letting x and y be arbitrary and assuming $x \neq y$ to be true, we see in light of (2.167) that $\{x, y\} \neq \{x\}$ follows to be also true. Since x is the neutral element of $\{x, y\}$ with respect to the join/addition in the semiring (5.170), which element we may therefore denote by 0_X with $X = \{x, y\}$, we see that the given semiring is nontrivial by definition. □

It will also be useful for us to consider the following connection between multiplication and the neutral element for addition (given it exists in X).

Definition 5.15 (Zero divisor, zero-divisor-free semiring). For any semiring $(X, +, \cdot)$ for which the zero element 0_X of X with respect to the addition $+$ exists, we say that an element $a \in X$ is a *zero divisor* iff

1. a is not identical with the zero element, that is,

$$a \neq 0_X, \tag{5.172}$$

   and

2. there exists an element b in X also different from the zero element such that $a \cdot b = 0_X$ or $b \cdot a = 0_X$, that is,

$$\exists b\, (b \in X \;\wedge\; b \neq 0_X \;\wedge\; [a \cdot b = 0_X \;\vee\; b \cdot a = 0_X]). \tag{5.173}$$

Furthermore, we say that a semiring $(X, +, \cdot)$ with zero element 0_X is *zero-divisor free* iff there does not exist a zero divisor in X, i.e. iff

$$\neg\exists a\, (a \in X \;\wedge\; a \neq 0_X \;\wedge\; \exists b\, (b \in X \;\wedge\; b \neq 0_X \;\wedge\; (a \cdot b = 0_X \;\vee\; b \cdot a = 0_X))). \tag{5.174}$$

Based on this definition of a zero divisor, the following theorem gives two equivalent conditions for a set X to contain no zero divisors.

Theorem 5.42 (Criterion for zero-divisor freeness). *Any semiring $(X, +, \cdot)$ with zero element 0_X is zero-divisor free iff*

$$\forall a, b\, (a, b \in X \Rightarrow [(a \cdot b = 0_X \vee b \cdot a = 0_X) \Rightarrow (a = 0_X \vee b = 0_X)]), \tag{5.175}$$

or equivalently iff

$$\forall a, b\, (a, b \in X \Rightarrow [(a \neq 0_X \wedge b \neq 0_X) \Rightarrow (a \cdot b \neq 0_X \wedge b \cdot a \neq 0_X)]). \tag{5.176}$$

Proof. We let X, $+$ and $\cdot$ be arbitrary sets and assume that $(X,+,\cdot)$ is a semiring for which X contains the zero element 0_X with respect to the addition $+$. Then, zero-divisor freeness is by definition equivalent to (5.174), which negation we may write equivalently as

$$\forall a\,([a \in X \wedge a \neq 0_X] \Rightarrow \neg\exists b\,(b \in X \wedge b \neq 0_X \wedge [a \cdot b = 0_X \vee b \cdot a = 0_X])]). \tag{5.177}$$

by applying the Negation Law for existential conjunctions. To prove the first of the stated equivalences, we assume first that $(X,+,\cdot)$ is zero-divisor free, i.e. we assume that $(X,+,\cdot)$ satisfies (5.177), and we show that this implies (5.175). To do this, we take arbitrary $\bar{a}$ and $\bar{b}$, assume $\bar{a},\bar{b} \in X$ to be true, and prove the second implication by contradiction, assuming

$$\bar{a} \cdot \bar{b} = 0_X \vee \bar{b} \cdot \bar{a} = 0_X \tag{5.178}$$

and $\neg(\bar{a} = 0_X \vee \bar{b} = 0_X)$ to be true. The latter negation implies with De Morgan's Law for sentences (1.52) that $\bar{a} \neq 0_X$ and $\bar{b} \neq 0_X$ are both true. Then, the truth of $\bar{a} \in X$ and of $\bar{a} \neq 0_X$ implies with the assumed (5.177) the truth of

$$\neg\exists b\,(b \in X \wedge b \neq 0_X \wedge [\bar{a} \cdot b = 0_X \vee b \cdot \bar{a} = 0_X]),$$

which negation in turn implies

$$\forall b\,([b \in X \wedge b \neq 0_X] \Rightarrow \neg[\bar{a} \cdot b = 0_X \vee b \cdot \bar{a} = 0_X]),$$

the Negation Law for existential conjunctions. Since $\bar{b} \in X$ and $\bar{b} \neq 0_X$ are both true, we therefore obtain the true negation

$$\neg[\bar{a} \cdot \bar{b} = 0_X \vee \bar{b} \cdot \bar{a} = 0_X],$$

which contradicts the true disjunction (5.178). Thus, the proof by contradiction is complete, and since $\bar{a},\bar{b}$ were arbitrary, we may therefore conclude that the semiring satisfies (5.175), so that the first part ('$\Rightarrow$') of the first proposed equivalence holds.

To prove the second part ('$\Leftarrow$') of that equivalence, we now assume (5.175) to be true, and we show that (5.177) also holds. Letting $\bar{a}$ be arbitrary, we may now prove the implication in (5.177) by contradiction, assuming the conjunction of $\bar{a} \in X$ and $\bar{a} \neq 0_X$ as well as the negation of the negated existential sentence to be true. Because of the Double Negation Law, the latter assumption yields the existential sentence

$$\exists b\,(b \in X \wedge b \neq 0_X \wedge [\bar{a} \cdot b = 0_X \vee b \cdot \bar{a} = 0_X]),$$

so that there is a particular constant $\bar{b}$ satisfying $\bar{b} \in X$, $\bar{b} \neq 0_X$ and the disjunction $\bar{a} \cdot \bar{b} = 0_X \lor \bar{b} \cdot \bar{a} = 0_X$. Now, the truth of $\bar{a}, \bar{b} \in X$ and the truth of the preceding disjunction imply with the assumed (5.175) that $\bar{a} = 0_X \lor \bar{b} = 0_X$ holds, which disjunction further implies the negated conjunction $\neg(\bar{a} \neq 0_X \land \bar{b} \neq 0_X)$. Since we previously established the true negations $\bar{a} \neq 0_X$ and $\bar{b} \neq 0_X$, we have that the conjunction $\bar{a} \neq 0_X \land \bar{b} \neq 0_X$ also holds, so that we obtained a contradiction. Thus, the proof of the implication in (5.177) is complete, and as a was arbitrary, we may therefore conclude that (5.177) holds, which completes the proof of the first proposed equivalence. Since X, $+$ and $\cdot$ were initially arbitrary, this equivalence is then true for any such sets. □

Exercise 5.27. Establish the second proposed equivalence in Theorem 5.42.

Proposition 5.43. *It is true for any zero-divisor free semiring $(X, +, \cdot)$ and any set $A \subseteq X$, such that A contains the zero element 0_X of X with respect to the addition $+$ and such that the restrictions of the addition and the multiplication to $A \times A$ are binary operations (on A) that the induced semiring $(X, +_A, \cdot_A)$ is zero-divisor free.*

Proof. We first let $(X, +, \cdot)$ be an arbitrary zero-divisor-free semiring and A an arbitrary subset of X. Next, we assume that A contains the zero element 0_X of X with respect to the addition $+$ and furthermore that the restrictions $+_A$ and $\cdot_A$ of the addition $+$ and the multiplication $\cdot$ to $A \times A$ are binary operations on A. In view of Note 5.15, $(A, +_A, \cdot_A)$ is then indeed a semiring. In addition, as the zero element 0_X of X is contained in A, that element is also the zero element of A with respect to $+_A$, as shown by Proposition 5.13. To demonstrate that $(A, +_A, \cdot_A)$ is zero-divisor free, we apply the Criterion for zero-divisor freeness and verify accordingly

$$\forall a, b\,(a, b \in A \Rightarrow [(a \neq 0_X \land b \neq 0_X) \Rightarrow (a \cdot_A b \neq 0_X \land b \cdot_A a \neq 0_X)]). \tag{5.179}$$

For this purpose, we take two arbitrary elements $a, b \in A$ satisfying $a \neq 0_X$ and $b \neq 0_X$. Since the assumed inclusion $A \subseteq X$, $a, b \in A$ implies $a, b \in X$ with the definition of a subset. In conjunction with the preceding inequalities, this implies $a \cdot b \neq 0_X$ and $b \cdot a \neq 0_X$ in view of (5.176) and the initial assumption that $(X, +, \cdot)$ is a zero-divisor-free semiring. Since $a, b \in A$ implies the equalities $a \cdot b = a \cdot_A b$ and $b \cdot a = b \cdot_A a$, we obtain the desired inequalities $a \cdot_A b \neq 0_X$ and $b \cdot_A a \neq 0_X$ via substitutions. As a and b were arbitrary, we may therefore conclude that the universal sentence (5.179) holds, so that the semiring $(A, +_A, \cdot_A)$ is indeed zero-divisor free. Since $(X, +, \cdot)$ and A were initially also arbitrary, we may now further conclude that the stated proposition holds. □

Proposition 5.44. *For any x it is true that the semiring* $(\{x\}, \sqcup, \sqcap)$ *in (5.169) is zero-divisor free.*

Proof. We take an arbitrary x and demonstrate that (5.175) is true for the semiring (5.169). For this purpose, we let a and b be arbitrary and assume that $a, b \in \{x\}$ holds. This assumption implies $a = x$ and $b = x$ with (2.169), so that the disjunction $a = 0_X \lor b = 0_X$ is true, because $0_X = x$ is the zero element in $\{x\}$ with respect to the join/addition in the semiring (5.169). Therefore, the implications in (5.175) are clearly true for the given semiring. Since a and b are arbitrary, we may therefore conclude that this semiring satisfies the Criterion for zero-divisor freeness. As x was also arbitrary, we my then further conclude that the proposed universal sentence is true. □

Proposition 5.45. *For any x and any y satisfying $x \neq y$ it is true that the semiring* $(\{x, y\}, \sqcup, \sqcap)$ *in (5.170) is zero-divisor free.*

Proof. We let x and y be arbitrary such that $x \neq y$ holds and show that the semiring (5.170) satisfies (5.176). To do this, we let $a, b \in \{x, y\}$ be arbitrary and assume $a \neq x \land b \neq x$ to be true, recalling x is the zero element 0_X in $X = \{x, y\}$ with respect to the addition/join $\sqcup$. Now, $a \in \{x, y\}$ shows in light of the definition of a pair that $a = x \lor a = y$ holds; since $a = x$ is false according to the first part of the assumed conjunction, we have that the second part $a = y$ of the preceding disjunction is true. Similarly, $b \in \{x, y\}$ yields the disjunction $b = x \lor b = y$, where $b = x$ is false according to the second part of the assumed conjunction, so that $b = y$ is true. We may now apply substitutions based on the equations $a = y$ and $b = y$ to obtain

$$a \sqcap b = y \sqcap y = y,$$
$$b \sqcap a = y \sqcap y = y,$$

where we also exploited the idempotence of $\sqcap$ (recalling Exercise 5.13). Then, initial assumption $x \neq y$ gives $x \neq a \sqcap b$ as well as $x \neq b \sqcap a$. Since we defined the meet $\sqcap$ to be the multiplication in the semiring (5.170), we may write these findings as $a \cdot b \neq 0_X \land b \cdot a \neq 0_X$, and because a and b are arbitrary, we may therefore conclude that the given semiring satisfies indeed (5.176). As x and y were initially also arbitrary, it then follows that the proposition holds, as claimed. □

5.3. The Semiring $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$

In this section, we will define the two binary operations of addition and multiplication on the set of natural numbers, which will be seen to be symbolic representations of the way we could accomplish this task literally manually by merging (in case of addition) or duplicating (in case of multiplication) collections of objects. We begin with the addition on the set of natural numbers, whose definition will be based on counting the total number of elements that are in two given disjoint sets.

Theorem 5.46. *The following sentences are true.*

a) For any $m, n \in \mathbb{N}$, the Cartesian products

$$M = \{1, \ldots, m\} \times \{0\}, \tag{5.180}$$

$$N = \{1, \ldots, n\} \times \{1\} \tag{5.181}$$

are disjoint sets with respective cardinality m and n, i.e. the Cartesian products M and N satisfy

$$|M| = m \wedge |N| = n \wedge M \cap N = \emptyset. \tag{5.182}$$

b) For any $m, n \in \mathbb{N}$, the cardinality of the union of two disjoint sets with respective cardinalities m and n is unique in the sense that

$$\begin{aligned} \forall M, N, M', N' \, ([|M| = m \wedge |N| = n \wedge M \cap N = \emptyset \\ \wedge |M'| = m \wedge |N'| = n \wedge M' \cap N' = \emptyset] \\ \Rightarrow |M \cup N| = |M' \cup N'|). \end{aligned} \tag{5.183}$$

c) There exists a unique set $+_{\mathbb{N}}$ such that an element z is in $+_{\mathbb{N}}$ iff z is in $(\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ and moreover if z is some ordered triple $((m, n), s)$ such that m and n are the cardinalities of some disjoint sets M and N and such that s is the cardinality of the union of M and N, i.e.

$$\begin{aligned} \exists! +_{\mathbb{N}} \, \forall z \, (z \in +_{\mathbb{N}} \Leftrightarrow [z \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N} \wedge \exists m, n, M, N, s \, (m = |M| \\ \wedge n = |N| \wedge M \cap N = \emptyset \wedge s = |M \cup N| \wedge ((m, n), s) = z)]). \end{aligned}$$

d) This set $+_{\mathbb{N}}$ is an addition on $\mathbb{N}$ satisfying

$$(m, n) \mapsto m +_{\mathbb{N}} n = |[\{1, \ldots, m\} \times \{0\}] \cup [\{1, \ldots, n\} \times \{1\}]|. \tag{5.184}$$

e) Furthermore, the addition $+_{\mathbb{N}}$ on $\mathbb{N}$ satisfies for any $m, n \in \mathbb{N}$

$$\forall M, N \, (|M| = m \wedge |N| = n \wedge M \cap N = \emptyset] \Rightarrow m +_{\mathbb{N}} n = |M \cup N|). \tag{5.185}$$

Proof. We let m and n be arbitrary natural numbers. Concerning a), we observe that the Cartesian products (5.180) and (5.181) have the cardinalities $|M| = m$ and $|N| = n$ in view of (4.508). It remains to show that M and N are disjoint. For this purpose, we notice that $0 \neq 1$ holds according to (4.165), which inequality further implies $\{0\} \cap \{1\} = \emptyset$ with (2.174), and therefore we obtain

$$(\{1, \ldots, m\} \times \{0\}) \cap (\{1, \ldots, n\} \times \{1\}) = \emptyset$$

with (3.55), which gives the desired $M \cap N = \emptyset$ after substitution. We thus proved the multiple conjunction (5.182), and since m and n were arbitrary, we may therefore conclude that a) is true.

Concerning b), we let m and n be arbitrary natural numbers and let M, N, M', N' be arbitrary sets with $|M| = |M'| = m$, $|N| = |N'| = n$ and $M \cap N = M' \cap N' = \emptyset$. To show that these assumptions imply $|M \cup N| = |M' \cup N'|$, we will construct in the following a bijection from $M \cup N$ to $M' \cup N'$, using the fact that the finiteness of the sets M, N, M' and N' implies the finiteness of $M \cup N$ and $M' \cup N'$ with Theorem 4.114. To begin with, $m = |M|$ and $m = |M'|$ imply with the definition of a cardinality that there exist bijections from $\{1, \ldots, m\}$ to M and from $\{1, \ldots, m\}$ to M', say

$$\bar{c} : \{1, \ldots, m\} \rightleftarrows M, \tag{5.186}$$
$$\bar{c}' : \{1, \ldots, m\} \rightleftarrows M'. \tag{5.187}$$

Similarly, $n = |N|$ and $n = |N'|$ imply the existence of bijections from $\{1, \ldots, n\}$ to N and from $\{1, \ldots, n\}$ to N', say

$$\bar{d} : \{1, \ldots, n\} \rightleftarrows N, \tag{5.188}$$
$$\bar{d}' : \{1, \ldots, n\} \rightleftarrows N'. \tag{5.189}$$

Now, (5.186) and (5.188) give the bijections

$$\bar{c}^{-1} : M \rightleftarrows \{1, \ldots, m\}$$
$$\bar{d}^{-1} : N \rightleftarrows \{1, \ldots, n\}$$

with (3.683) and then in connection with (5.187) as well as (5.189)

$$\bar{c}' \circ \bar{c}^{-1} : M \rightleftarrows M', \tag{5.190}$$
$$\bar{d}' \circ \bar{d}^{-1} : N \rightleftarrows N'. \tag{5.191}$$

because (3.672). Thus, M is the domain of $\bar{c}' \circ \bar{c}^{-1}$ and N the domain of $\bar{d}' \circ \bar{d}^{-1}$. As we assumed $M \cap N = \emptyset$, it follows with Exercise 3.73 that $\bar{c}' \circ \bar{c}^{-1}$

and $\bar{d}' \circ \bar{d}^{-1}$ are compatible functions (having disjoint domains). Therefore, the pair $\{\bar{c}' \circ \bar{c}^{-1}, \bar{d}' \circ \bar{d}^{-1}\}$ is a set of compatible functions according to Proposition 3.174, so that

$$\bar{e} = \bigcup \{\bar{c}' \circ \bar{c}^{-1}, \bar{d}' \circ \bar{d}^{-1}\} = \bar{c}' \circ \bar{c}^{-1} \cup \bar{d}' \circ \bar{d}^{-1} \tag{5.192}$$

(using the definition of the union of a pair) is a function because of Theorem 3.175a). Moreover, the pair $\{M, N\}$ consists of the domains of $\bar{c}' \circ \bar{c}^{-1}$ and $\bar{d}' \circ \bar{d}^{-1}$, so that the domain of $\bar{e}$ is given by $M \cup N$ due to Theorem 3.175b).

We now show that $\bar{e}$ is a surjection from $M \cup N$ to $M' \cup N'$, by verifying

$$\forall y\, (y \in M' \cup N' \Leftrightarrow \exists x\, (\bar{e}(x) = y)) \tag{5.193}$$

according to Corollary 3.191. For this purpose, we let y be arbitrary and prove the implication directly, assuming $y \in M' \cup N'$ to be true. By definition of the union of two sets, the disjunction $y \in M' \vee y \in N'$ is true, which we now use to prove the existential sentence in (5.193) by cases. Let us observe for this purpose that the ranges of the bijections (5.190) and (5.191) are M' and N', respectively.

If $y \in M'$ $[= \mathrm{ran}(\bar{c}' \circ \bar{c}^{-1})]$ holds, then there exists by definition of a range an element, say $\bar{x}$, with

$$(\bar{x}, y) \in \bar{c}' \circ \bar{c}^{-1}. \tag{5.194}$$

Since

$$\bar{c}' \circ \bar{c}^{-1} \subseteq \bar{e} \quad [= \bar{c}' \circ \bar{c}^{-1} \cup \bar{d}' \circ \bar{d}^{-1}]$$

holds with (2.201), it follows from (5.194) that $(\bar{x}, y) \in \bar{e}$is true , which we may also write as $y = \bar{e}(\bar{x})$ since $\bar{e}$ is a function. Thus, the truth of $\bar{e}(\bar{x}) = y$ shows that the existential sentence in (5.193) holds in case of $y \in M'$.

If $y \in N'$ $[= \mathrm{ran}(\bar{d}' \circ \bar{d}^{-1})]$ holds, then we may apply the same arguments as in the first case to infer the truth of the existential sentence to be proven. There now exists an element, say $\bar{x}'$, such that

$$(\bar{x}', y) \in \bar{d}' \circ \bar{d}^{-1}. \tag{5.195}$$

Because of

$$\bar{d}' \circ \bar{d}^{-1} \subseteq \bar{e} \quad [= \bar{c}' \circ \bar{c}^{-1} \cup \bar{d}' \circ \bar{d}^{-1}],$$

we have that (5.195) implies $(\bar{x}', y) \in \bar{e}$ and therefore $y = \bar{e}(\bar{x}')$. Thus, the existential sentence in (5.193) holds also in case of $y \in N'$, completing the proof of the first part of the equivalence in (5.193).

To prove the second part ('$\Leftarrow$'), we now assume that there exists a constant, say $\bar{\bar{x}}$, satisfying $\bar{e}(\bar{\bar{x}}) = y$. Thus,

$$(\bar{\bar{x}}, y) \in \bar{e} \quad [= \bar{c}' \circ \bar{c}^{-1} \cup \bar{d}' \circ \bar{d}^{-1}]$$

holds, so that the disjunction of $(\bar{\bar{x}}, y) \in \bar{c}' \circ \bar{c}^{-1}$ and $(\bar{\bar{x}}, y) \in \bar{d}' \circ \bar{d}^{-1}$ follows to be true by definition of the union of two sets. We may therefore apply a proof by cases to establish the desired consequent $y \in M' \cup N'$.

In case of $(\bar{\bar{x}}, y) \in \bar{c}' \circ \bar{c}^{-1}$, it follows (by definition of a range) that

$$y \in M' \; [= \mathrm{ran}(\bar{c}' \circ \bar{c}^{-1})]$$

is true. Here, $M' \subseteq M' \cup N'$ holds with (2.201), so that $y \in M'$ implies the desired $y \in M' \cup N'$ (using the definition of a subset).

In the other case of $(\bar{\bar{x}}, y) \in \bar{d}' \circ \bar{d}^{-1}$, we obtain

$$y \in N' \; [= \mathrm{ran}(\bar{d}' \circ \bar{d}^{-1})]$$

by applying the definition of a range. Now, $N' \subseteq M' \cup N'$ holds (again with (2.201)), and then $y \in N'$ implies $y \in M' \cup N'$ (again by definition of a subset), as desired.

Thus, the existential sentence in (5.193) implies $y \in M' \cup N'$ in any case, completing the proof of the equivalence in (5.193). As y is arbitrary, we may therefore conclude that the universal sentence (5.193) is true, so that $\bar{e}$ is indeed a surjection from $M \cup N$ to $M' \cup N'$.

Next, we prove that $\bar{e}$ is also an injection from $M \cup N$ to $M' \cup N'$ by verifying

$$\forall x, x' \, ([x, x' \in M \cup N \, \wedge \, \bar{e}(x) = \bar{e}(x')] \Rightarrow x = x'). \tag{5.196}$$

We let x and x' be arbitrary and assume both $x, x' \in M \cup N$ and the equation(s) $\bar{e}(x) = \bar{e}(x')$ $[= y]$ to be true, which we may write as

$$(x, y), (x', y) \in \bar{e} \quad [= \bar{c}' \circ \bar{c}^{-1} \, \cup \, \bar{d}' \circ \bar{d}^{-1}] \tag{5.197}$$

Since we already established $\bar{e}$ as a surjection with codomain/range $M' \cup N'$, we may infer from (5.197) the truth of $y \in M' \cup N'$ $[= \mathrm{ran}(\bar{e})]$ with the definition of a range. Consequently, the definition of the union of two sets yields the true disjunction $y \in M' \vee y \in N'$, which we now employ to prove $x = x'$ by cases.

Regarding the first case, if $y \in M'$ holds, then we may prove the sentence $(x, y) \notin \bar{d}' \circ \bar{d}^{-1}$ by contradiction. To do this, we assume the negation of that sentence to be true, which gives $(x, y) \in \bar{d}' \circ \bar{d}^{-1}$ with the Double Negation Law, which implies

$$y \in N' \; [= \mathrm{ran}(\bar{d}' \circ \bar{d}^{-1})] \tag{5.198}$$

with the definition of a range. Thus, the conjunction $y \in M' \, \wedge \, y \in N'$ is true, which yields $y \in M' \cap N'$ by definition of the intersection of two sets, so that there exists an element in $M' \in N'$. Consequently, $M' \cap N' \neq \emptyset$ holds according to (2.42), which is in contradiction to the initial assumption $M' \cap N' = \emptyset$ and which thus proves $(x, y) \notin \bar{d}' \circ \bar{d}^{-1}$. Now, (5.197) shows in light of the definition of the union of two sets that the disjunction of $(x, y) \in \bar{c}' \circ \bar{c}^{-1}$ and $(x, y) \in \bar{d}' \circ \bar{d}^{-1}$ is true, where $(x, y) \in \bar{d}' \circ \bar{d}^{-1}$ is false, as shown before. Therefore, $(x, y) \in \bar{c}' \circ \bar{c}^{-1}$ is true, which we may write on the one hand in function notation as

$$y = \bar{c}' \circ \bar{c}^{-1}(x), \tag{5.199}$$

and which yields on the other hand $x \in M$ $[= \mathrm{dom}(\bar{c}' \circ \bar{c}^{-1})]$ by definition of a domain.

In the same way, we may now establish $y = \bar{c}' \circ \bar{c}^{-1}(x')$ as well as $x' \in M$, by proving first via contradiction that the sentence $(x', y) \notin \bar{d}' \circ \bar{d}^{-1}$ holds. Assuming for this purpose the negation of that sentence to hold, we obtain $(x', y) \in \bar{d}' \circ \bar{d}^{-1}$, and this evidently gives (5.198) again. Thus, $y \in M' \wedge y \in N'$ is also true, which yields $y \in M' \cap N'$, so that $M' \cap N' \neq \emptyset$ holds, in contradiction to the initial assumption $M' \cap N' = \emptyset$. This completes the proof of $(x', y) \notin \bar{d}' \circ \bar{d}^{-1}$, and since (5.197) shows that $(x', y) \in \bar{c}' \circ \bar{c}^{-1}$ or $(x', y) \in \bar{d}' \circ \bar{d}^{-1}$ is true, we may infer from this disjunction and the preceding negation that $(x', y) \in \bar{c}' \circ \bar{c}^{-1}$ holds indeed. Then, we may write this as

$$y = \bar{c}' \circ \bar{c}^{-1}(x'), \tag{5.200}$$

and we obtain moreover $x' \in M$ $[= \mathrm{dom}(\bar{c}' \circ \bar{c}^{-1})]$.

We may now combine the equations (5.199) and (5.200) to obtain the new equation $\bar{c}' \circ \bar{c}^{-1}(x) = \bar{c}' \circ \bar{c}^{-1}(x')$. Together with the already established $x, x' \in M$, this further implies the desired $x = x'$, because the bijection $\bar{c}' \circ \bar{c}^{-1}$ is in particular an injection (with domain M).

Regarding the other case $y \in N'$, we may apply similar arguments to infer from this assumption the truth of $x = x'$. First, we prove by contradiction that $(x, y) \notin \bar{c}' \circ \bar{c}^{-1}$ is true. Assuming the negation of the preceding negation to holds, so that $(x, y) \in \bar{c}' \circ \bar{c}^{-1}$ follows to be true, we obtain

$$y \in M' \ [= \mathrm{ran}(\bar{c}' \circ \bar{c}^{-1})], \tag{5.201}$$

which shows in view of the case assumption $y \in N'$ that the intersection $M' \cap N'$ is not empty. As this contradicts the initial assumption $M' \cap N' = \emptyset$, we may infer from this that $(x, y) \notin \bar{c}' \circ \bar{c}^{-1}$ is indeed true. As mentioned before, the disjunction of $(x, y) \in \bar{c}' \circ \bar{c}^{-1}$ and $(x, y) \in \bar{d}' \circ \bar{d}^{-1}$ holds, where we just established the first part as false, so that $(x, y) \in \bar{d}' \circ \bar{d}^{-1}$ is true. On the one hand, we may write this as

$$y = \bar{d}' \circ \bar{d}^{-1}(x), \tag{5.202}$$

and on the other hand we see that $x \in N$ $[= \mathrm{dom}(\bar{d}' \circ \bar{d}^{-1})]$ holds.

Next, we establish via contradiction the truth of the sentence $(x', y) \notin \bar{c}' \circ \bar{c}^{-1}$, assuming that its negation is true, so that $(x', y) \in \bar{c}' \circ \bar{c}^{-1}$ holds. This yields again (5.201), so that y is both in M' and in N', with the consequence that $M' \cap N' \neq \emptyset$, in contradiction to the assumed $M' \cap N' = \emptyset$. This proves $(x', y) \notin \bar{c}' \circ \bar{c}^{-1}$, and as the disjunction of $(x', y) \in \bar{c}' \circ \bar{c}^{-1}$ and $(x', y) \in \bar{d}' \circ \bar{d}^{-1}$ is true, we may therefore infer from this the truth of $(x', y) \in \bar{d}' \circ \bar{d}^{-1}$. We may then on the one hand write this as

$$y = \bar{d}' \circ \bar{d}^{-1}(x'), \tag{5.203}$$

and we furthermore see that $x' \in N$ $[= \mathrm{dom}(\bar{d}' \circ \bar{d}^{-1})]$ holds. Let us now combine the equations (5.202) and (5.203) to form $\bar{d}' \circ \bar{d}^{-1}(x) = \bar{d}' \circ \bar{d}^{-1}(x')$ and notice that $x, x' \in N$ is also true. Then, as the bijection $\bar{d}' \circ \bar{d}^{-1}$ is especially an injection (with domain N), it follows that $x = x'$ holds, as in the first case.

Now, since x and x' were arbitrary, we may therefore conclude that (5.196) is true, which means that the function $\bar{e} : M \cup N \to M' \cup N'$ is an injection. Together with the previous finding that $\bar{e}$ is a surjection from $M \cup N$ to $M' \cup N'$, this shows that $\bar{e} : M \cup N \to M' \cup N'$ is a bijection. We thus proved that there exists a bijection from $M \cup N$ to $M' \cup N'$, which existential sentence then implies with Proposition 4.107 the equinumerosity of the (finite) sets $M \cup N$ and $M' \cup N'$, i.e. the equation $|M \cup N| = |M' \cup N'|$. Since M, N, M' and N' were initially arbitrary sets, we may further conclude that the proposed universal sentence (5.183) is true. Then, as m and n were also arbitrary, we may finally conclude that b) holds.

Concerning c), we apply the Axiom of Specification and the Axiom of Extension to obtain the stated uniquely existential sentence. Thus, the set $+_{\mathbb{N}}$ is uniquely characterized by

$$\begin{aligned} &\forall z\, (z \in +_{\mathbb{N}} \Leftrightarrow [z \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N} \wedge \exists m, n, M, N, s\, (m = |M| \\ &\quad \wedge n = |N| \wedge M \cap N = \emptyset \wedge s = |M \cup N| \wedge ((m, n), s) = z)]). \end{aligned} \tag{5.204}$$

Concerning d), since $z \in +_{\mathbb{N}}$ implies in particular $z \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ for any z, it follows by definition of a subset that $+_{\mathbb{N}} \subseteq (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ holds. We now apply the Function Criterion to prove that $+_{\mathbb{N}}$ is a function from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$. For this purpose, we verify

$$\forall x\, (x \in \mathbb{N} \times \mathbb{N} \Rightarrow \exists! s\, (s \in \mathbb{N} \wedge (x, s) \in +_{\mathbb{N}})). \tag{5.205}$$

We let $\bar{x} \in \mathbb{N} \times \mathbb{N}$ be arbitrary, which implies by definition of the Cartesian product of two sets that there exist elements of $\mathbb{N}$, say $\bar{m}$ and $\bar{n}$, with

$(\bar{m}, \bar{n}) = \bar{x}$. In view of a), the Cartesian products

$$\bar{M} = \{1, \ldots, \bar{m}\} \times \{0\},$$
$$\bar{N} = \{1, \ldots, \bar{n}\} \times \{1\}$$

are disjoint sets with cardinalities $|\bar{M}| = \bar{m}$ and $|\bar{N}| = \bar{n}$. As $\bar{M}$ and $\bar{N}$ are finite sets, their union $\bar{M} \cup \bar{N}$ is also finite due to Theorem 4.114, so that there exist by definition a natural number, say $\bar{s}$, and a bijection from $\{1, \ldots, \bar{s}\}$ to $\bar{M} \cup \bar{N}$. This bijection shows that the set $\bar{M} \cup \bar{N}$ has the cardinality $\bar{s} = |\bar{M} \cup \bar{N}|$ in view of the definition of a cardinality. Let us now observe that the true equations $(\bar{m}, \bar{n}) = \bar{x}$ and $\bar{s} = \bar{s}$ imply with the Equality Criterion for ordered pairs $((\bar{m}, \bar{n}), \bar{s}) = (\bar{x}, \bar{s})$. We thus showed that the multiple conjunction

$$\bar{m} = |\bar{M}| \wedge \bar{n} = |\bar{N}| \wedge \bar{M} \cap \bar{N} = \emptyset \wedge \bar{s} = |\bar{M} \cup \bar{N}| \wedge ((\bar{m}, \bar{n}), \bar{s}) = (\bar{x}, \bar{s})$$

holds, so that $\bar{z} = (\bar{x}, \bar{s})$ satisfies the existential sentence in (5.204). Because $\bar{x} \in \mathbb{N} \times \mathbb{N}$ and $\bar{s} \in \mathbb{N}$ imply (by definition of the Cartesian product of two sets) that

$$(\bar{x}, \bar{s}) \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$$

also holds, we obtain now $(\bar{x}, \bar{s}) \in +_{\mathbb{N}}$ with (5.204). Observing now that $\bar{s}$, as a cardinality, is by definition a natural number, we thus have that the existential sentence

$$\exists s \, (s \in \mathbb{N} \wedge (\bar{x}, s) \in +_{\mathbb{N}})$$

is true, so that the proof of the existential part of the uniquely existential sentence in (5.205) is complete.

To prove the uniqueness part, we verify

$$\forall s, s' \, ([s \in \mathbb{N} \wedge (\bar{x}, s) \in +_{\mathbb{N}} \wedge s' \in \mathbb{N} \wedge (\bar{x}, s') \in +_{\mathbb{N}}] \Rightarrow s = s'). \quad (5.206)$$

We let $\bar{s}$ and $\bar{s}'$ be arbitrary natural numbers with $(\bar{x}, \bar{s}) \in +_{\mathbb{N}}$ and $(\bar{x}, \bar{s}') \in +_{\mathbb{N}}$. It now follows from these assumptions with (5.204) in particular that there exist particular sets $\bar{m}$, $\bar{n}$, $\bar{M}$, $\bar{N}$ and $\bar{s}$, as well as particular sets $\bar{m}'$, $\bar{n}'$, $\bar{M}'$, $\bar{N}'$ and $\bar{s}'$ satisfying the multiple conjunctions

$$\begin{aligned} &\bar{m} = |\bar{M}| \wedge \bar{n} = |\bar{N}| \wedge \bar{M} \cap \bar{N} = \emptyset \wedge \bar{s} = |\bar{M} \cup \bar{N}| && (5.207) \\ &\quad \wedge ((\bar{m}, \bar{n}), \bar{s}) = (\bar{x}, \bar{s}), \\ &\bar{m}' = |\bar{M}'| \wedge \bar{n}' = |\bar{N}'| \wedge \bar{M}' \cap \bar{N}' = \emptyset \wedge \bar{s}' = |\bar{M}' \cup \bar{N}'| && (5.208) \\ &\quad \wedge ((\bar{m}', \bar{n}'), \bar{s}') = (\bar{x}, \bar{s}'), \end{aligned}$$

which give in particular $((\bar{m}, \bar{n}), \bar{s}) = (\bar{x}, \bar{s})$ and $((\bar{m}', \bar{n}'), \bar{s}') = (\bar{x}, \bar{s})$. The former equation further implies in particular $(\bar{m}, \bar{n}) = \bar{x}$ and the latter in particular $(\bar{m}', \bar{n}') = \bar{x}$ with the Equality Criterion for ordered pairs. These equations then yield after substitution $(\bar{m}, \bar{n}) = (\bar{m}', \bar{n}')$, which gives $\bar{m} = \bar{m}'$ and $\bar{n} = \bar{n}'$, using again the Equality Criterion for ordered pairs. Applying now substitutions based on these equations, (5.207) and (5.208) give the multiple conjunction

$$\begin{gathered}|\bar{M}| = \bar{m} \,\wedge\, |\bar{N}| = \bar{n} \,\wedge\, \bar{M} \cap \bar{N} = \emptyset \\ \wedge\, |\bar{M}'| = \bar{m} \,\wedge\, |\bar{N}'| = \bar{n} \,\wedge\, \bar{M}' \cap \bar{N}' = \emptyset,\end{gathered}$$

which implies $|\bar{M} \cup \bar{N}| = |\bar{M}' \cup \bar{N}'|$ with (5.183). Since (5.207) and (5.208) imply in particular $\bar{s} = |\bar{M} \cup \bar{N}|$ and $\bar{s}' = |\bar{M}' \cup \bar{N}'|$, we then obtain with the preceding finding the desired $\bar{s} = \bar{s}'$. Because $\bar{s}$ and $\bar{s}'$ are arbitrary, we may therefore conclude that (5.206) holds, which universal sentence proves the uniqueness part. Thus, the proof of the uniquely existential sentence in (5.205) is complete, and since $\bar{x}$ is arbitrary, we may now further conclude that the universal sentence (5.205) is true. It then follows with the Function Criterion that $+_{\mathbb{N}}$ is a function from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$; thus, $+_{\mathbb{N}}$ is a uniquely specified binary operation on $\mathbb{N}$, which we may view as an addition. To prove that an ordered pair formed by any natural numbers is mapped according to (5.184), we now establish the universal sentence

$$\forall m, n\, (m, n \in \mathbb{N} \Rightarrow m +_{\mathbb{N}} n = |[\{1, \ldots, m\} \times \{0\}] \cup [\{1, \ldots, n\} \times \{1\}]|). \tag{5.209}$$

We let $\bar{m}$ and $\bar{n}$ be arbitrary and assume $\bar{m}, \bar{n} \in \mathbb{N}$ to be true, which yields $(\bar{m}, \bar{n}) \in \mathbb{N} \times \mathbb{N}$ with the definition of the Cartesian product of two sets. According to a), we may define the Cartesian products

$$\begin{aligned}\bar{M} &= \{1, \ldots, \bar{m}\} \times \{0\}, \\ \bar{N} &= \{1, \ldots, \bar{n}\} \times \{1\},\end{aligned}$$

which satisfy

$$|\bar{M}| = \bar{m} \,\wedge\, |\bar{N}| = \bar{n} \,\wedge\, \bar{M} \cap \bar{N} = \emptyset.$$

According to b), the cardinality $\bar{s} = |\bar{M} \cup \bar{N}|$ is determined and constitutes thus a natural number, so that we obtain (again by definition of the Cartesian product of two sets)

$$((\bar{m}, \bar{n}), \bar{s}) \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}. \tag{5.210}$$

Moreover, the preceding equations show that the existential sentence

$$\begin{aligned}\exists m, n, M, N, s\, (&m = |M| \,\wedge\, n = |N| \,\wedge\, M \cap N = \emptyset \,\wedge\, s = |M \cup N| \\ &\wedge\, ((m, n), s) = ((\bar{m}, \bar{n}), |\bar{M} \cup \bar{N}|))\end{aligned}$$

holds. Then, the conjunction of (5.210) and the preceding existential sentence implies in view of (5.204) that $((\bar{m}, \bar{n}), |\bar{M} \cup \bar{N}|) \in +_{\mathbb{N}}$, which we may write in addition notation with the definitions of the sets $\bar{M}$ and $\bar{N}$ as

$$\bar{m} +_{\mathbb{N}} \bar{n} = |[\{1, \ldots, \bar{m}\} \times \{0\}] \cup [\{1, \ldots, \bar{n}\} \times \{1\}]|. \tag{5.211}$$

Since $\bar{m}$ and $\bar{n}$ were arbitrary, we may therefore conclude that (5.209) holds, so that the addition $+_{\mathbb{N}}$ on $\mathbb{N}$ is indeed characterized by the mapping (5.184).

Concerning e), we let m and n be arbitrary, assume $m, n \in \mathbb{N}$, let $\bar{M}$ and $\bar{N}$ be arbitrary sets, and assume

$$|\bar{M}| = m \wedge |\bar{N}| = n \wedge \bar{M} \cap \bar{N} = \emptyset \tag{5.212}$$

to be true. Let us now recall for the sets (5.180) and (5.181) the truth of

$$|M| = m \wedge |N| = n \wedge M \cap N = \emptyset \tag{5.213}$$

according to (5.182). We then obtain from the conjunction of (5.212) and (5.213) the equation $|\bar{M} \cup \bar{N}| = |M \cup N|$ with (5.183), and therefore with (5.184)

$$\begin{aligned} \bar{m} +_{\mathbb{N}} \bar{n} &= |[\{1, \ldots, \bar{m}\} \times \{0\}] \cup [\{1, \ldots, \bar{n}\} \times \{1\}]| \\ &= |M \cup N| \\ &= |\bar{M} \cup \bar{N}|, \end{aligned}$$

proving the implication in (5.185). Since $\bar{M}$ and $\bar{N}$ are arbitrary, we may therefore conclude that the universal sentence (5.185) holds. Because m and n were initially also arbitrary, we may further conclude that e) is true. □

Definition 5.16 (Addition on the set of natural numbers). We call

$$+_{\mathbb{N}} : \mathbb{N} \times \mathbb{N} \to \mathbb{N}, \quad (m, n) \mapsto m +_{\mathbb{N}} n \tag{5.214}$$

the *addition on the set of natural numbers*.

Proposition 5.47. *It is true that* 0 *is the neutral element of* $\mathbb{N}$ *with respect to the addition* $+_{\mathbb{N}}$ *on* $\mathbb{N}$.

Proof. We verify

$$\forall n \, (n \in \mathbb{N} \Rightarrow [0 +_{\mathbb{N}} n = n \wedge n +_{\mathbb{N}} 0 = n]), \tag{5.215}$$

letting $n \in \mathbb{N}$ be arbitrary. Now, the set $M = \{1, \ldots, n\}$ satisfies

$$|M| = n \tag{5.216}$$

with (4.506), and the set $N = \emptyset$ is finite (by definition) with cardinality $|N| = 0$ according to (4.527). Furthermore,

$$M \cap N = M \cap \emptyset = \emptyset$$

holds due to (2.62), which we may write equivalently as

$$N \cap M = \emptyset$$

by using (2.58). Thus, the multiple conjunctions

$$\begin{aligned}&|M| = n \wedge |N| = \emptyset \wedge M \cap N = \emptyset \\ &|N| = \emptyset \wedge |M| = n \wedge N \cap M = \emptyset\end{aligned}$$

hold, so that we may form the sums

$$\begin{aligned}n +_{\mathbb{N}} 0 &= |M \cup N| = |M \cup \emptyset| = |M| = n \\ 0 +_{\mathbb{N}} n &= |N \cup M| = |\emptyset \cup M| = |M| = n\end{aligned}$$

by applying (5.185), substitution based on $N = \emptyset$, (2.216), and (5.216). These equations give the desired conjunction of $0 +_{\mathbb{N}} n = n$ and $n +_{\mathbb{N}} 0 = n$, which proves the implication (5.215). Since n was arbitrary, it then follows that (5.215) holds, so that 0 is by definition the identity in $\mathbb{N}$ with respect to $+_{\mathbb{N}}$. □

Proposition 5.48. *The successor of a natural number n is identical with the sum of n and 1, that is,*

$$\forall n \, (n \in \mathbb{N} \Rightarrow n^+ = n +_{\mathbb{N}} 1). \tag{5.217}$$

Proof. We let n be an arbitrary natural number and observe first the truth of the multiple conjunction

$$|\{1, \ldots, n\}| = n \wedge |\{n^+\}| = 1 \wedge \{1, \ldots, n\} \cap \{n^+\} = \emptyset \tag{5.218}$$

in light of (4.506), (4.528) and (4.243). We now obtain the true equations

$$\begin{aligned}n +_{\mathbb{N}} 1 &= |\{1, \ldots, n\} \cup \{n^+\}| \\ &= |\{1, \ldots, n^+\}| \\ &= n^+\end{aligned}$$

with Theorem 5.46e), (4.241) and (4.506), as desired. Since n was arbitrary, it then follows that the proposed universal sentence (5.217) is true. □

Note 5.17. Since we established in Proposition 2.102 the natural number 2 as the successor of the natural number 1, we now obtain in view of (5.217) the set-theoretical justification of

$$1 +_{\mathbb{N}} 1 = 2.$$

Exercise 5.28. Establish the following equations for any $m, n \in \mathbb{N}$.

$$\begin{aligned} m +_{\mathbb{N}} n &= |[\{1, \ldots, m\} \times \{0\}] \cup [\{1, \ldots, n\} \times \{2\}]| \qquad (5.219) \\ &= |[\{1, \ldots, m\} \times \{1\}] \cup [\{1, \ldots, n\} \times \{2\}]|. \qquad (5.220) \end{aligned}$$

(Hint: Use Theorem 5.46a,b), (5.211), (4.508), (4.169), (4.167), (2.174), and (3.55).)

Theorem 5.49 (Associative Law for the addition on $\mathbb{N}$). *The addition $+_{\mathbb{N}}$ on $\mathbb{N}$ is associative.*

Proof. To prove that the binary operation $+_{\mathbb{N}}$ on $\mathbb{N}$ is associative, we verify

$$\forall m, n, p \, (m, n, p \in \mathbb{N} \Rightarrow (m +_{\mathbb{N}} n) +_{\mathbb{N}} p = m +_{\mathbb{N}} (n +_{\mathbb{N}} p)). \qquad (5.221)$$

Letting m, n and p be arbitrary natural numbers, we first define the sets

$$\begin{aligned} M &= \{1, \ldots, m\} \times \{0\}, \\ N &= \{1, \ldots, n\} \times \{1\}, \\ P &= \{1, \ldots, p\} \times \{2\}, \end{aligned}$$

which have the cardinalities

$$\begin{aligned} |M| &= m, \qquad (5.222) \\ |N| &= n, \qquad (5.223) \\ |P| &= p \qquad (5.224) \end{aligned}$$

due to (4.508). We now apply (5.211) as well as (5.220) to form the sums

$$\begin{aligned} m +_{\mathbb{N}} n &= |M \cup N|, \qquad (5.225) \\ n +_{\mathbb{N}} p &= |N \cup P|. \qquad (5.226) \end{aligned}$$

Next, we recall that $0 \neq 1$, $1 \neq 2$ and $0 \neq 2$ hold according to (4.165) – (4.169), which inequalities imply with (2.174)

$$\begin{aligned} \{0\} \cap \{1\} &= \emptyset, \\ \{1\} \cap \{2\} &= \emptyset, \\ \{0\} \cap \{2\} &= \emptyset, \end{aligned}$$

and therefore with (3.55)

$$\begin{aligned}(\{1,\ldots,m\}\times\{0\})\cap(\{1,\ldots,n\}\times\{1\})&=\emptyset, \qquad (5.227)\\ (\{1,\ldots,n\}\times\{1\})\cap(\{1,\ldots,p\}\times\{2\})&=\emptyset,\\ (\{1,\ldots,m\}\times\{0\})\cap(\{1,\ldots,p\}\times\{2\})&=\emptyset,\end{aligned}$$

which equations yield after substitution

$$M\cap N=\emptyset, \tag{5.228}$$

$$N\cap P=\emptyset, \tag{5.229}$$

$$M\cap P=\emptyset. \tag{5.230}$$

On the one hand, we obtain with the previous findings the true equations

$$\begin{aligned}M\cap(N\cup P)&=(M\cap N)\cup(M\cap P)\\ &=\emptyset\cup\emptyset\\ &=\emptyset\end{aligned} \tag{5.231}$$

by using the Distributive Law for the intersection of two sets, (5.223) together with (5.225), and (2.216). Thus, the multiple conjunction

$$|M|=m\;\wedge\;|N\cup P|=n+_{\mathbb{N}}p\;\wedge\;M\cap(N\cup P)=\emptyset$$

holds in view of (5.222), (5.226) and (5.231), which conjunction yields with (5.185) the sum

$$m+_{\mathbb{N}}(n+_{\mathbb{N}}p)=|M\cup(N\cup P)|. \tag{5.232}$$

On the other hand, we obtain

$$\begin{aligned}(M\cup N)\cap P&=P\cap(M\cup N)\\ &=(P\cap M)\cup(P\cap N)\\ &=(M\cap P)\cup(N\cap P)\\ &=\emptyset\cup\emptyset\\ &=\emptyset\end{aligned} \tag{5.233}$$

by applying the Commutative Law for the intersection of two sets, the Distributive Law for the intersection of two sets, again the preceding Commutative Law, then (5.230) alongside (5.229), and finally (2.216). Thus, we see that the multiple conjunction

$$|M\cup N|=m+_{\mathbb{N}}n\;\wedge\;|P|=p\;\wedge\;(M\cup N)\cap P=\emptyset \tag{5.234}$$

holds in light of (5.225), (5.224) and (5.233), and this conjunction gives

$$\begin{aligned}(m +_{\mathbb{N}} n) +_{\mathbb{N}} p &= |(M \cup N) \cup P| \\ &= |M \cup (N \cup P)| \\ &= m +_{\mathbb{N}} (n +_{\mathbb{N}} p),\end{aligned}$$

where we applied also the Associative Law for the union of two sets and the previously established sume (5.232).

This finding proves the implication in (5.222), and since m, n and p were arbitrary, we may therefore conclude that the universal sentence (5.221) is true. Thus, the addition $+_{\mathbb{N}}$ is an associative binary operation by definition. □

Note 5.18. In view of the Associative Law for the addition on $\mathbb{N}$, the ordered pair $(\mathbb{N}, +_{\mathbb{N}})$ is a semigroup.

Theorem 5.50 (Commutative Law for the addition on $\mathbb{N}$). *The addition $+_{\mathbb{N}}$ on the set of natural numbers is a commutative binary operation.*

Exercise 5.29. Prove the Commutative Law for the addition on $\mathbb{N}$.

(Hint: Proceed similarly as in the proof of Theorem 5.49, applying now (2.214) instead of (2.219).)

Note 5.19. The ordered pair $(\mathbb{N}, +_{\mathbb{N}})$ is a commutative semigroup.

The *product of two natural numbers* m and n can be defined through a 'duplication' process via the Cartesian product of sets M and N with cardinalities m and n, respectively.

Theorem 5.51 (Multiplication on the set of natural numbers). *The following sentences are true.*

a) For any $m, n \in \mathbb{N}$, the initial segments of $\mathbb{N}_+$

$$M = \{1, \ldots, m\} \tag{5.235}$$

$$N = \{1, \ldots, n\} \tag{5.236}$$

are sets with respective cardinality m and n, i.e. the sets M and N satisfy

$$|M| = m \wedge |N| = n. \tag{5.237}$$

b) For any $m, n \in \mathbb{N}$, the cardinality of the Cartesian product of two sets with respective cardinalities m and n is unique in the sense that

$$\begin{aligned}&\forall M, N, M', N' \, ([|M| = m \wedge |N| = n \wedge |M'| = m \wedge |N'| = n] \\ &\quad \Rightarrow |M \times N| = |M' \times N'|).\end{aligned} \tag{5.238}$$

c) There exists a unique set $\cdot_{\mathbb{N}}$ *such that an element* z *is in* $\cdot_{\mathbb{N}}$ *iff* z *is in* $(\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ *and moreover if* z *is some ordered triple* $((m,n),p)$ *such that* m *and* n *are the cardinalities of some sets* M *and* N *and such that* p *is the cardinality of the Cartesian product of* M *and* N*, i.e.*

$$\exists! \cdot_{\mathbb{N}} \forall z\,(z \in \cdot_{\mathbb{N}} \Leftrightarrow [z \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N} \wedge \exists m,n,M,N,s\,(m = |M| \\ \wedge\ n = |N| \wedge p = |M \times N| \wedge ((m,n),p) = z)]).$$

d) This set $\cdot_{\mathbb{N}}$ *is a multiplication on* $\mathbb{N}$ *satisfying*

$$(m,n) \mapsto m \cdot_{\mathbb{N}} n = |\{1,\ldots,m\} \times \{1,\ldots,n\}|. \tag{5.239}$$

e) Furthermore, the multiplication $\cdot_{\mathbb{N}}$ *on* $\mathbb{N}$ *satisfies for any* $m,n \in \mathbb{N}$

$$\forall M,N\,(|M| = m \wedge |N| = n] \Rightarrow m \cdot_{\mathbb{N}} n = |M \times N|). \tag{5.240}$$

Proof. Concerning b), we take arbitrary sets m, n, M, N, M', and N', and we assume $m,n \in \mathbb{N}$, $|M| = |M'| = m$ as well as $|N| = |N'| = n$ to be true. Let us now observe in light of Theorem 4.121 that the finiteness of the sets M and N implies the finiteness of the Cartesian product $M \times N$, and that for the same reason the finiteness of M' and N' implies the finiteness of the Cartesian product $M' \times N'$. To prove that these two Cartesian products satisfy the stated equation $|M \times N| = |M' \times N'|$, we establish now a bijection from $M \times N$ to $M' \times N'$.

On the one hand, the two assumed equations $m = |M|$ and $m = |M'|$ imply by definition of a cardinality that there are two particular corresponding bijections

$$\bar{c} : \{1,\ldots,m\} \rightleftarrows M, \tag{5.241}$$
$$\bar{c}' : \{1,\ldots,m\} \rightleftarrows M'. \tag{5.242}$$

On the other hand, the other two assumed equations $n = |N|$ and $n = |N'|$ imply (again with the definition of a cardinality) the existence of particular bijections

$$\bar{d} : \{1,\ldots,n\} \rightleftarrows N, \tag{5.243}$$
$$\bar{d}' : \{1,\ldots,n\} \rightleftarrows N'. \tag{5.244}$$

Let us observe here that the values $\bar{c}(i)$, $\bar{d}(j)$, $\bar{c}'(i)$ and $\bar{d}'(j)$ are specified for all $i \in \{1,\ldots,m\}$ and all $j \in \{1,\ldots,n\}$, since $\{1,\ldots,m\}$ is the domain of $\bar{c}$ as well as of $\bar{c}'$ and since $\{1,\ldots,n\}$ is the domain of $\bar{d}$ as well as of $\bar{d}'$.

We may therefore apply the Axiom of Specification in connection with the Equality Criterion for sets to obtain the true uniquely existential sentence

$$\exists! \bar{e} \forall z \, (z \in \bar{e} \Leftrightarrow [z \in (M \times N) \times (M' \times N') \, \wedge \, \exists i, j \, (i \in \{1, \ldots, m\} \\ \wedge \, j \in \{1, \ldots, n\} \, \wedge \, ((\bar{c}(i), \bar{d}(j)), (\bar{c}'(i), \bar{d}'(j))) = z)]).$$

Thus, the set $\bar{e}$ is uniquely characterized by

$$\forall z \, (z \in \bar{e} \Leftrightarrow [z \in (M \times N) \times (M' \times N') \, \wedge \, \exists i, j \, (i \in \{1, \ldots, m\} \\ \wedge \, j \in \{1, \ldots, n\} \, \wedge \, ((\bar{c}(i), \bar{d}(j)), (\bar{c}'(i), \bar{d}'(j))) = z)]). \tag{5.245}$$

Then, $z \in \bar{e}$ implies in particular $z \in (M \times N) \times (M' \times N')$ for any z, which means that $\bar{e}$ is included in $(M \times N) \times (M' \times N')$ by definition of a subset. Applying the notation $A = M \times N$ and $B = M' \times N'$, we may therefore treat $\bar{e}$ as a binary relation relation with $\bar{e} \subseteq A \times B$.

We now apply the Function Criterion to prove that $\bar{e}$ is a function from $M \times N$ to $M' \times N'$, and verify accordingly

$$\forall x \, (x \in M \times N \Rightarrow \exists! y \, (y \in M' \times N' \, \wedge \, (x, y) \in \bar{e})). \tag{5.246}$$

Letting $\bar{x} \in M \times N$ be arbitrary, we first establish the existential part. To begin with, it follows by definition of the Cartesian product of two sets that there exist elements, say $\bar{m}$ and $\bar{n}$, such that $\bar{m} \in M$, $\bar{n} \in N$ and $(\bar{m}, \bar{n}) = \bar{x}$ hold. Since the bijections $\bar{c}$ and $\bar{d}$ are in particular surjections with codomain M and N, respectively, we have that M is the range of $\bar{c}$ and that N is the range of $\bar{d}$. Consequently, $\bar{m} \in M$, $\bar{n} \in N$ imply that there exist elements, say $\bar{i}$ and $\bar{j}$, with $(\bar{i}, \bar{m}) \in \bar{c}$ and with $(\bar{j}, \bar{n}) \in \bar{d}$. On the one hand, we may write these findings in function notation as

$$\bar{c}(\bar{i}) = \bar{m}, \tag{5.247}$$

$$\bar{d}(\bar{j}) = \bar{n}. \tag{5.248}$$

On the other hand, it follows by definition of a domain that $\bar{i} \in \{1, \ldots, m\}$ [$=$ $\mathrm{dom}(\bar{c})$] and $\bar{j} \in \{1, \ldots, n\}$ [$= \mathrm{dom}(\bar{d})$] hold with (5.241) and (5.243). Since $\{1, \ldots, m\} = \mathrm{dom}(\bar{c}')$ and $\{1, \ldots, n\} = \mathrm{dom}(\bar{d}')$ are also true according to (5.242) and (5.244), it follows (again by definition of a domain) that there exist elements, say $\bar{\bar{m}}$ and $\bar{\bar{n}}$, such that $(\bar{i}, \bar{\bar{m}}) \in \bar{c}'$ and $(\bar{j}, \bar{\bar{n}}) \in \bar{d}'$. We therefore obtain on the one hand

$$\bar{c}'(\bar{i}) = \bar{\bar{m}}, \tag{5.249}$$

$$\bar{d}'(\bar{j}) = \bar{\bar{n}}, \tag{5.250}$$

and on the other hand it follows (by definition of a range) that $\bar{\bar{m}} \in M'$ [$=$ $\mathrm{ran}(\bar{c}')$] and $\bar{\bar{n}} \in N'$ [$= \mathrm{ran}(\bar{d}')$]. In view of the existence of the values $\bar{c}(\bar{i})$,

$\bar{d}(\bar{j})$, $\bar{c}'(\bar{i})$ and $\bar{d}'(\bar{j})$ in (5.247) – (5.250), the ordered pairs $(\bar{c}(\bar{i}), \bar{d}(\bar{j}))$ $[= \bar{x}]$ and $\bar{y} = (\bar{c}'(\bar{i}), \bar{d}'(\bar{j}))$ are uniquely specified, and then the ordered pair

$$\bar{z} = ((\bar{c}(\bar{i}), \bar{d}(\bar{j})), (\bar{c}'(\bar{i}), \bar{d}'(\bar{j}))) = ((\bar{m}, \bar{n}), (\bar{\bar{m}}, \bar{\bar{n}})) = (\bar{x}, \bar{y})$$

also exists. Together with the previously established $\bar{i} \in \{1, \ldots, m\}$ and $\bar{j} \in \{1, \ldots, n\}$, this proves that $\bar{z}$ satisfies the existential sentence in (5.245). We now verify that $\bar{z}$ satisfies also the first part of the conjunction in (5.245). Besides the initially chosen element $\bar{x} \in M \times N$, we also have $\bar{y} = (\bar{\bar{m}}, \bar{\bar{n}})$, which equation implies together with $\bar{\bar{m}} \in M'$ and $\bar{\bar{n}} \in N'$ (by definition of the Cartesian product of two sets) that $\bar{y} \in M' \times N'$ holds. Then, the conjunction of $\bar{x} \in M \times N$, $\bar{y} \in M' \times N'$ and $\bar{z} = (\bar{x}, \bar{y})$ further implies (using again the definition of the Cartesian product of two sets) the truth of $\bar{z} \in (M \times N) \times (M' \times N')$. Thus, $\bar{z}$ satisfies the conjunction on the right-hand side of the equivalence in (5.245), so that $\bar{z} = (\bar{x}, \bar{y})$ follows to be an element of $\bar{e}$, where $\bar{y} \in M' \times N'$. Therefore, $\bar{x}$ satisfies the existential part of the uniquely existential sentence in (5.246).

Regarding the uniqueness part, we prove

$$\forall y, y' \, ([y \in M' \times N' \;\wedge\; (\bar{x}, y) \in \bar{e} \;\wedge\; y' \in M' \times N' \;\wedge\; (\bar{x}, y') \in \bar{e}] \Rightarrow y = y'). \tag{5.251}$$

We let $\bar{y}$ and $\bar{y}'$ be arbitrary elements of $M' \times N'$ such that $(\bar{x}, \bar{y})$ and $(\bar{x}, \bar{y}')$ are in $\bar{e}$. On the one hand, $(\bar{x}, \bar{y})$ implies with (5.245) in particular that there exist an element of $\{1, \ldots, m\}$, say $\bar{i}$, and an element of $\{1, \ldots, n\}$, say $\bar{j}$, with

$$((\bar{c}(\bar{i}), \bar{d}(\bar{j})), (\bar{c}'(\bar{i}), \bar{d}'(\bar{j}))) = (\bar{x}, \bar{y}).$$

This equation then yields $(\bar{c}(\bar{i}), \bar{d}(\bar{j})) = \bar{x}$ and $(\bar{c}'(\bar{i}), \bar{d}'(\bar{j})) = \bar{y}$ with the Equality Criterion for ordered pairs. On the other hand, $(\bar{x}, \bar{y}') \in \bar{e}$ implies again with (5.245) in particular that there are an element of $\{1, \ldots, m\}$, say $\bar{i}'$, and an element of $\{1, \ldots, n\}$, say $\bar{j}'$, such that

$$((\bar{c}(\bar{i}'), \bar{d}(\bar{j}')), (\bar{c}'(\bar{i}'), \bar{d}'(\bar{j}'))) = (\bar{x}, \bar{y}').$$

This equation gives $(\bar{c}(\bar{i}'), \bar{d}(\bar{j}')) = \bar{x}$ and $(\bar{c}'(\bar{i}'), \bar{d}'(\bar{j}')) = \bar{y}'$, utilizing again the Equality Criterion for ordered pairs. Combining the previous two expressions for $\bar{x}$, we arrive at

$$[\bar{x} =] \quad (\bar{c}(\bar{i}), \bar{d}(\bar{j})) = (\bar{c}(\bar{i}'), \bar{d}(\bar{j}')),$$

which in turn implies $\bar{c}(\bar{i}) = \bar{c}(\bar{i}')$ and $\bar{d}(\bar{j}) = \bar{d}(\bar{j}')$, applying the Equality Criterion for ordered pairs once again. Since the bijection $\bar{c}$ is in particular an injection and since both $\bar{i}$ and $\bar{i}'$ are elements of the domain $\{1, \ldots, m\}$ of $\bar{c}$, it follows from $\bar{c}(\bar{i}) = \bar{c}(\bar{i}')$ that $\bar{i} = \bar{i}'$ holds. Similarly, as the bijection $\bar{d}$ is in particular an injection and as both $\bar{j}$ and $\bar{j}'$ are in the domain $\{1, \ldots, n\}$ of $\bar{d}$, it follows from $\bar{d}(\bar{j}) = \bar{d}(\bar{j}')$ that $\bar{j} = \bar{j}'$ is true. Consequently, we obtain via substitution

$$\bar{y} = (\bar{c}'(\bar{i}), \bar{d}'(\bar{j})) = (\bar{c}'(\bar{i}'), \bar{d}'(\bar{j}')) = \bar{y}',$$

which yields the desired $\bar{y} = \bar{y}'$. Since $\bar{y}$ and $\bar{y}'$ are arbitrary, we may therefore conclude that the universal sentence (5.251) holds, so that the proof of the uniqueness part of the uniquely existential sentence in (5.246) is complete. As $\bar{x}$ was also arbitrary, we may then further conclude that the universal sentence (5.246) is true, which implies with the Function Criterion that $\bar{e}$ is a function from $M \times N$ to $M' \times N'$, i.e.

$$\bar{e} : M \times N \to M' \times N'.$$

Let us now verify that $\bar{e}$ is a surjection. Since $M' \times N'$ is a codomain of $\bar{e}$, we see that $\operatorname{ran}(\bar{e}) \subseteq M' \times N'$ holds. We now establish the truth of $M' \times N' \subseteq \operatorname{ran}(\bar{e})$, i.e. of

$$\forall y \, (y \in M' \times N' \Rightarrow y \in \operatorname{ran}(\bar{e})). \tag{5.252}$$

For this purpose, we let $\bar{y} \in M' \times N'$ be arbitrary, which implies (by definition of the Cartesian product of two sets) that there exist an element in M', say $\bar{m}'$, and an element in N', say $\bar{n}'$, such that $(\bar{m}', \bar{n}') = \bar{y}$ holds. Recalling that the one-to-one correspondence $\bar{c}'$ is in particular an onto function with codomain/range M' and that the bijection $\bar{d}'$ is in particular a surjection with codomain/range N', it follows on the one hand from $\bar{m}' \in M'$ by definition of a range that there exists an element, say $\bar{i}$, with $(\bar{i}, \bar{m}') \in \bar{c}'$, which we may also write as $\bar{m}' = \bar{c}'(\bar{i})$. On the other hand, it follows from $\bar{n}' \in N'$ (again by definition of range) that there exists an element, say $\bar{j}$, such that $(\bar{j}, \bar{n}') \in \bar{d}'$, i.e. such that $\bar{n}' = \bar{d}'(\bar{j})$. Therefore, the previously established equation $\bar{y} = (\bar{m}', \bar{n}')$ becomes

$$\bar{y} = (\bar{c}'(\bar{i}), \bar{d}'(\bar{j})).$$

Let us also recall that $\{1, \ldots, m\}$ is the domain of $\bar{c}'$ and that $\{1, \ldots, n\}$ is the domain of $\bar{d}'$. Then, the previously obtained $(\bar{i}, \bar{m}') \in \bar{c}'$ and $(\bar{j}, \bar{n}') \in \bar{d}'$ imply by definition of a domain that $\bar{i} \in \{1, \ldots, m\}$ and that $\bar{j} \in \{1, \ldots, n\}$ hold. Since $\{1, \ldots, m\}$ is the domain also of $\bar{c}$ and $\{1, \ldots, n\}$ the domain of $\bar{d}$, it follows on the one hand from $\bar{i} \in \{1, \ldots, m\}$ that there exists an element, say $\bar{\bar{m}}$, with $(\bar{i}, \bar{\bar{m}}) \in \bar{c}$, i.e. with $\bar{\bar{m}} = \bar{c}(\bar{i})$. On the other hand, it follows from $\bar{j} \in \{1, \ldots, n\}$ that there is an element, say $\bar{\bar{n}}$, with $(\bar{j}, \bar{\bar{n}}) \in \bar{d}$, i.e. with $\bar{\bar{n}} = \bar{d}(\bar{j})$. Recaling now that M is the codomain/range of the bijection/surjection $\bar{c}$ and N the codomain/range of the bijection/surjection

$\bar{d}$, we have that $(\bar{i}, \bar{\bar{m}}) \in \bar{c}$ implies $\bar{\bar{m}} \in M$ and that $(\bar{j}, \bar{\bar{n}}) \in \bar{d}$ implies $\bar{\bar{n}} \in N$. Then, the ordered pair

$$\bar{x} = (\bar{\bar{m}}, \bar{\bar{n}}) = (\bar{c}(\bar{i}), \bar{d}(\bar{j}))$$

is specified and implies together with $\bar{\bar{m}} \in M$ and $\bar{\bar{n}} \in N$, by definition of the Cartesian product of two sets, that $\bar{x} \in M \times N$ is true. The ordered pair

$$\bar{z} = (\bar{x}, \bar{y}) = ((\bar{\bar{m}}, \bar{\bar{n}}), (\bar{m}', \bar{n}')) = ((\bar{c}(\bar{i}), \bar{d}(\bar{j})), (\bar{c}'(\bar{i}), \bar{d}'(\bar{j})))$$

is then also specified, so that the first of these equations implies with $\bar{x} \in M \times N$ and the initially assumed $\bar{y} \in M' \times N'$ (again by definition of the Cartesian product of two sets) that $\bar{z} \in (M \times N) \times (M' \times N')$ holds. The preceding equations also show that there exist i and j with $i \in \{1, \ldots, m\}$, $j \in \{1, \ldots, n\}$ and $((\bar{c}(i), \bar{d}(j)), (\bar{c}'(i), \bar{d}'(j))) = \bar{z}$. The conjunction of the previous two findings therefore implies with (5.245) that $[(\bar{x}, \bar{y}) =]\, \bar{z} \in \bar{e}$ holds. Thus, $(\bar{x}, \bar{y}) \in \bar{e}$ is true, which further implies $\bar{y} \in \mathrm{ran}(\bar{e})$ (applying the definition of a range). This completes the proof of the implication in (5.252), and since $\bar{y}$ was arbitrary, we may therefore conclude that (5.252) holds. It then follows from this with the definition of a subset that $M' \times N' \subseteq \mathrm{ran}(\bar{e})$ is indeed true. Together with the already mentioned fact $\mathrm{ran}(\bar{e}) \subseteq M' \times N'$, this gives then the equation $\mathrm{ran}(\bar{e}) = M' \times N'$ with the Axiom of Extension. Consequently, the function $\bar{e} : M \times N \to M' \times N'$ is a surjection, i.e.

$$\bar{e} : M \times N \twoheadrightarrow M' \times N'.$$

Next, we demonstrate that this surjection is also an injection from $M \times N$ to $M' \times N'$. To do this, we verify

$$\forall x, x' \,([x, x' \in M \times N \,\wedge\, \bar{e}(x) = \bar{e}(x')] \Rightarrow x = x'), \tag{5.253}$$

letting $\bar{x}$ and $\bar{x}'$ be arbitrary elements of $M \times N$ such that $\bar{e}(\bar{x}) = \bar{e}(\bar{x}')$ holds. Denoting this value of the function $\bar{e}$ by $\bar{y}$, we may then also write the preceding equations as $(\bar{x}, \bar{y}) \in \bar{e}$ and $(\bar{x}', \bar{y}) \in \bar{e}$. On the one hand, $(\bar{x}, \bar{y}) \in \bar{e}$ implies with (5.245) in particular that there exists an element of $\{1, \ldots, m\}$, say $\bar{i}$, and that there exists an element of $\{1, \ldots, n\}$, say $\bar{j}$, such that

$$((\bar{c}(\bar{i}), \bar{d}(\bar{j})), (\bar{c}'(\bar{i}), \bar{d}'(\bar{j}))) = (\bar{x}, \bar{y}).$$

Let us here notice that this equation yields $(\bar{c}(\bar{i}), \bar{d}(\bar{j})) = \bar{x}$ as well as $(\bar{c}'(\bar{i}), \bar{d}'(\bar{j})) = \bar{y}$ with the Equality Criterion for ordered pairs. On the other hand, $(\bar{x}', \bar{y}) \in \bar{e}$ implies with (5.245) in particular that there is an element in $\{1, \ldots, m\}$, say $\bar{i}'$, and that there is an element in $\{1, \ldots, n\}$, say $\bar{j}'$, satisfying

$$((\bar{c}(\bar{i}'), \bar{d}(\bar{j}')), (\bar{c}'(\bar{i}'), \bar{d}'(\bar{j}'))) = (\bar{x}', \bar{y}).$$

Then, this equation gives $(\bar{c}(\bar{i}'), \bar{d}(\bar{j}')) = \bar{x}'$ as well as $(\bar{c}'(\bar{i}'), \bar{d}'(\bar{j}')) = \bar{y}$ again with the Equality Criterion for ordered pairs. We thus obtained two expressions for $\bar{y}$, so that substitution yields

$$[\bar{y} =] \quad (\bar{c}'(\bar{i}), \bar{d}'(\bar{j})) = (\bar{c}'(\bar{i}'), \bar{d}'(\bar{j}')).$$

We may then evidently infer from these identical ordered pairs the truth of $\bar{c}'(\bar{i}) = \bar{c}'(\bar{i}')$ and $\bar{d}'(\bar{j}) = \bar{d}'(\bar{j}')$. Since $\bar{c}'$ and $\bar{d}'$ are one-to-one functions and since $\bar{i}, \bar{i}' \in \{1, \ldots, m\}$ as well as $\bar{j}, \bar{j}' \in \{1, \ldots, n\}$ holds, the previous two equations imply $\bar{i} = \bar{i}'$ and $\bar{j} = \bar{j}'$, respectively. Applying now substitutions based on these equations, we obtain

$$\bar{x} = (\bar{c}(\bar{i}), \bar{d}(\bar{j})) = (\bar{c}(\bar{i}'), \bar{d}(\bar{j}')) = \bar{x}',$$

so that $\bar{x} = \bar{x}'$ follows to be true, as desired. Because $\bar{x}$ and $\bar{x}'$ are arbitrary, we may therefore conclude that the universal sentence (5.253) holds, which shows that $\bar{e} : M \times N \to M' \times N'$ is an injection, that is,

$$\bar{e} : M \times N \hookrightarrow M' \times N'.$$

As the function $\bar{e}$ is both an injection and a surjection, this means that $\bar{e}$ is a bijection, i.e.

$$\bar{e} : M \times N \rightleftarrows M' \times N'.$$

We thus demonstrated the existence of a bijection from the finite set $M \times N$ to the finite set $M' \times N'$, so that $|M \times N| = |M' \times N'|$ follows to be true with Proposition 4.107. As M, N, M' and N' were arbitrary sets, we may therefore conclude that the universal sentence (5.238) is true, so that the proof of b) is complete.

Concerning c), we apply the Axiom of Specification and the Equality Criterion for sets to obtain the stated uniquely existential sentence, so that the set $\cdot_{\mathbb{N}}$ is uniquely characterized by

$$\begin{aligned} \forall z\, (z \in \cdot_{\mathbb{N}} \Leftrightarrow [z \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N} \,\wedge\, \exists m, n, M, N, p\, (m = |M| \\ \wedge\, n = |N| \,\wedge\, p = |M \times N| \,\wedge\, ((m, n), p) = z)]). \end{aligned} \tag{5.254}$$

Concerning d), we notice in light of (5.254) that $\cdot_{\mathbb{N}} \subseteq (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ holds by definition of a subset because $z \in \cdot_{\mathbb{N}}$ implies in particular $z \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ for all z. Next, we use the Function Criterion to show that $\cdot_{\mathbb{N}}$ is a function from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$. To do this, we prove

$$\forall x\, (x \in \mathbb{N} \times \mathbb{N} \Rightarrow \exists! p\, (p \in \mathbb{N} \,\wedge\, (x, p) \in \cdot_{\mathbb{N}})), \tag{5.255}$$

letting $\bar{x} \in \mathbb{N} \times \mathbb{N}$ be arbitrary. Consequently, there exist (by definition of the Cartesian product of two sets) elements of $\mathbb{N}$, say $\bar{m}$ and $\bar{n}$, such that $(\bar{m}, \bar{n}) = \bar{x}$ holds. Therefore, the initial segments of $\mathbb{N}_+$

$$\bar{M} = \{1, \ldots, \bar{m}\},$$
$$\bar{N} = \{1, \ldots, \bar{n}\}$$

are specified, where

$$|\bar{M}| = |\{1, \ldots, \bar{m}\}| = \bar{m},$$
$$|\bar{N}| = |\{1, \ldots, \bar{n}\}| = \bar{n}$$

are true because of Corollary 4.104. The Cartesian product $\bar{M} \times \bar{N}$ of the finite sets $\bar{M}$ and $\bar{N}$ is itself finite in view of Theorem 4.121, which fact then implies the existence of particular natural number $\bar{p}$ and of a particular bijection $\bar{c} : \{1, \ldots, \bar{p}\} \rightleftarrows \bar{M} \times \bar{N}$; thus, the definition of a cardinality yields $\bar{p} = |\bar{M} \times \bar{N}|$ $[\in \mathbb{N}]$. Consequently, the truth of $\bar{x} \in \mathbb{N} \times \mathbb{N}$ and of $\bar{p} \in \mathbb{N}$ shows that the ordered pair $\bar{z} = (\bar{x}, \bar{p})$ is an element of $(\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$. Furthermore, since the previous findings demonstrate the truth of the multiple conjunction

$$\bar{m} = |\bar{M}| \wedge \bar{n} = |\bar{N}| \wedge \bar{p} = |\bar{M} \times \bar{N}| \wedge ((\bar{m}, \bar{n}), \bar{p}) = \bar{z},$$

we see that $\bar{z}$ satisfies the right-hand side of the equivalence in (5.254), so that $\bar{z}$ follows to be in $\cdot_{\mathbb{N}}$. This means that $(\bar{x}, \bar{p}) \in \cdot_{\mathbb{N}}$ holds (alongside $\bar{p} \in \mathbb{N}$), so that there exists a set p such that the conjunction $p \in \mathbb{N} \wedge (x, p) \in \cdot_{\mathbb{N}}$ is true. This completes the proof of the existential part of the uniquely existential sentence in (5.255).

It remains for us to prove the uniqueness part, for which we verify

$$\forall p, p' \left([p \in \mathbb{N} \wedge (\bar{x}, p) \in \cdot_{\mathbb{N}} \wedge p' \in \mathbb{N} \wedge (\bar{x}, p') \in \cdot_{\mathbb{N}}] \Rightarrow p = p' \right). \quad (5.256)$$

For this purpose, we let $\bar{p}$ and $\bar{p}'$ be arbitrary in $\mathbb{N}$ such that $(\bar{x}, \bar{p})$ and $(\bar{x}, \bar{p}')$ are elements of $\cdot_{\mathbb{N}}$. Then, $(\bar{x}, \bar{p}) \in \cdot_{\mathbb{N}}$ implies with (5.254) that $(\bar{x}, \bar{p})$ is in $(\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ and that there are sets, say $\bar{m}$, $\bar{n}$, $\bar{M}$, $\bar{N}$ and $\bar{p}$, satisfying the multiple conjunction

$$\bar{m} = |\bar{M}| \wedge \bar{n} = |\bar{N}| \wedge \bar{p} = |\bar{M} \times \bar{N}| \wedge ((\bar{m}, \bar{n}), \bar{p}) = (\bar{x}, \bar{p}). \quad (5.257)$$

Similarly, $(\bar{x}, \bar{p}') \in \cdot_{\mathbb{N}}$ implies that $(\bar{x}, \bar{p}')$ is in $(\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ and that there exist sets, say $\bar{m}'$, $\bar{n}'$, $\bar{M}'$, $\bar{N}'$ and $\bar{p}'$ such that

$$\bar{m}' = |\bar{M}'| \wedge \bar{n}' = |\bar{N}'| \wedge \bar{p}' = |\bar{M}' \times \bar{N}'| \wedge ((\bar{m}', \bar{n}'), \bar{p}') = (\bar{x}, \bar{p}'). \quad (5.258)$$

Now, (5.257) and (5.258) show in particular that the equations $((\bar{m}, \bar{n}), \bar{p}) = (\bar{x}, \bar{p})$ and $((\bar{m}', \bar{n}'), \bar{p}') = (\bar{x}, \bar{p}')$ are true. Here, the former equation gives in particular $(\bar{m}, \bar{n}) = \bar{x}$ and the latter in particular $(\bar{m}', \bar{n}') = \bar{x}$ because of the Equality Criterion for ordered pairs. Combining these equations via substitution, we obtain $(\bar{m}, \bar{n}) = (\bar{m}', \bar{n}')$, which then further implies $\bar{m} = \bar{m}'$ and $\bar{n} = \bar{n}'$ again with the Equality Criterion for ordered pairs. We may now apply further substitutions based on these equations in (5.257) and (5.258) to obtain the conjunction

$$|\bar{M}| = \bar{m} \;\wedge\; |\bar{N}| = \bar{n} \;\wedge\; |\bar{M}'| = \bar{m} \;\wedge\; |\bar{N}'| = \bar{n},$$

which then yields $|\bar{M} \times \bar{N}| = |\bar{M}' \times \bar{N}'|$ with (5.238). As the multiple conjunctions (5.257) and (5.258) show in particular that $\bar{p} = |\bar{M} \times \bar{N}|$ and $\bar{p}' = |\bar{M}' \times \bar{N}'|$ are true, we find after substitutions based on the preceding three equations $\bar{p} = \bar{p}'$, as desired. Since $\bar{p}$ and $\bar{p}'$ are arbitrary, (5.256) follows then to be true, which completes the proof of the uniqueness part and thus the proof of the uniquely existential sentence in (5.255). As $\bar{x}$ was also arbitrary, we may now further conclude that (5.255) holds, from which it follows with the Function Criterion that $\cdot_{\mathbb{N}}$ is a function from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$. We thus proved that $\cdot_{\mathbb{N}}$ is a uniquely specified binary operation on $\mathbb{N}$, which we may consider to be a multiplication. To establish the mapping (5.239), we verify

$$\forall m, n \,(m, n \in \mathbb{N} \Rightarrow m \cdot_{\mathbb{N}} n = |\{1, \ldots, m\} \times \{1, \ldots, n\}). \tag{5.259}$$

We let $\bar{m}, \bar{n} \in \mathbb{N}$ be arbitrary, so that we obtain $(\bar{m}, \bar{n}) \in \mathbb{N} \times \mathbb{N}$ by definition of the Cartesian product of two sets. According to a), we may define the sets

$$\bar{M} = \{1, \ldots, \bar{m}\}$$
$$\bar{N} = \{1, \ldots, \bar{n}\}$$

with cardinalities

$$|\bar{M}| = \bar{m} \;\wedge\; |\bar{N}| = \bar{n}.$$

Since b) shows that the cardinality $\bar{p} = |\bar{M} \times \bar{N}|$ is a specified natural number, we furthermore obtain (again by definition of the Cartesian product of two sets)

$$((\bar{m}, \bar{n}), \bar{p}) \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}. \tag{5.260}$$

Evidently, the existential sentence

$$\exists m, n, M, N, s \,(m = |M| \;\wedge\; n = |N| \;\wedge\; p = |M \times N|$$
$$\wedge\; ((m, n), p) = ((\bar{m}, \bar{n}), |\bar{M} \times \bar{N}|))$$

is true, which implies together with (5.260) $((\bar{m},\bar{n}),|\bar{M}\times\bar{N}|)\in\cdot_{\mathbb{N}}$ according to (5.254); using the notation for a multiplication and the definitions of the sets $\bar{M}$ and $\bar{N}$, we may therefore write

$$\bar{m}\cdot_{\mathbb{N}}\bar{n}=|\{1,\ldots,\bar{m}\}\times\{1,\ldots,\bar{n}\}|. \tag{5.261}$$

As $\bar{m}$ and $\bar{n}$ were arbitrary, we may therefore conclude that (5.259) is true, which shows that the multiplication $\cdot_{\mathbb{N}}$ on $\mathbb{N}$ is characterized by (5.239). □

Exercise 5.30. Establish Theorem 5.51a,e).

Definition 5.17 (Multiplication on the set of natural numbers). We call

$$\cdot_{\mathbb{N}}:\mathbb{N}\times\mathbb{N}\to\mathbb{N},\quad (m,n)\mapsto m\cdot_{\mathbb{N}}n \tag{5.262}$$

the *multiplication on the set of natural numbers*.

Theorem 5.52 (Associative Law for the multiplication on $\mathbb{N}$). *The multiplication $\cdot_{\mathbb{N}}$ on the set of natural numbers is an associative binary operation.*

Proof. To demonstrate the associativity of the binary operation $\cdot_{\mathbb{N}}$ on $\mathbb{N}$, we prove the universal sentence

$$\forall m,n,p\,(m,n,p\in\mathbb{N}\Rightarrow(m\cdot_{\mathbb{N}}n)\cdot_{\mathbb{N}}p=m\cdot_{\mathbb{N}}(n\cdot_{\mathbb{N}}p)). \tag{5.263}$$

For this purpose, we let m, n and p be arbitrary natural numbers, so that the initial segments

$$\begin{aligned} M &= \{1,\ldots,m\},\\ N &= \{1,\ldots,n\},\\ P &= \{1,\ldots,p\}\end{aligned}$$

have the required cardinalities $|M|=m$, $|N|=n$ and $|P|=p$, as shown by (4.506). Consequently, we may apply (5.239) to form the products

$$m\cdot_{\mathbb{N}}n = |M\times N|, \tag{5.264}$$

$$n\cdot_{\mathbb{N}}p = |N\times P|. \tag{5.265}$$

Since the conjunction

$$|M|=m\wedge|N\times P|=n\cdot_{\mathbb{N}}p$$

is then evidently true, we may use (5.240) to form the product

$$m\cdot_{\mathbb{N}}(n\cdot_{\mathbb{N}}p)=|M\times(N\times P)|. \tag{5.266}$$

Moreover, the conjunction

$$|M \times N| = m \cdot_{\mathbb{N}} n \, \wedge \, |P| = p$$

holds as well, so that we obtain the equations

$$\begin{aligned}(m \cdot_{\mathbb{N}} n) \cdot_{\mathbb{N}} p &= |(M \times N) \times P| \\ &= |M \times (N \times P)| \\ &= m \cdot_{\mathbb{N}} (n \cdot_{\mathbb{N}} p)\end{aligned}$$

applying (5.240), then Proposition 4.122d), and finally (5.266).

Because m, n and p were arbitrary, it then follows that (5.263) is true, and therefore the multiplication $\cdot_{\mathbb{N}}$ is an associative binary operation. □

Note 5.20. We now see that the ordered pair $(\mathbb{N}, \cdot_{\mathbb{N}})$ is a semigroup.

Theorem 5.53 (Commutative Law for the multiplication on $\mathbb{N}$). *The addition $\cdot_{\mathbb{N}}$ on the set of natural numbers is a commutative binary operation.*

Exercise 5.31. Prove the Commutative Law for the multiplication on $\mathbb{N}$.

(Hint: Proceed similarly as in the proof of Theorem 5.52, applying Exercise 4.37.)

Note 5.21. The ordered pair $(\mathbb{N}, \cdot_{\mathbb{N}})$ is a commutative semigroup.

Proposition 5.54. *It is true that* 1 *is the neutral element of* $\mathbb{N}$ *with respect to the multiplication* $\cdot_{\mathbb{N}}$ *on* $\mathbb{N}$.

Proof. We prove the universal sentence

$$\forall n \, (n \in \mathbb{N} \Rightarrow [1 \cdot_{\mathbb{N}} n = n \, \wedge \, n \cdot_{\mathbb{N}} 1 = n]), \tag{5.267}$$

letting n be arbitrary in $\mathbb{N}$. We observe that the set $M = \{1, \ldots, n\}$ has the cardinality $|M| = n$ according to (4.506), and that the singleton $N = \{1\}$ is finite with cardinality $|N| = 1$ due to (4.470) and (4.529). Since the conjunctions $|M| = n \, \wedge \, |N| = 1$ and $|N| = 1 \, \wedge \, |M| = n$ are thus true, we may form the products $n \cdot_{\mathbb{N}} 1$ and $1 \cdot_{\mathbb{N}} n$, and we obtain

$$1 \cdot_{\mathbb{N}} n = n \cdot_{\mathbb{N}} 1 = |M \times N| = |\{1, \ldots, n\} \times \{1\}| = n,$$

by applying the Commutative Law for the multiplication on $\mathbb{N}$, 5.240, substitutions based on the equations $M = \{1, \ldots, n\}$ as well as $N = \{1\}$, and (4.508). These equations yield $1 \cdot_{\mathbb{N}} n = n$ and $n \cdot_{\mathbb{N}} 1 = n$, as desired. As n was arbitrary, (5.267) therefore follows to be true, so that 1 is by definition the identity in $\mathbb{N}$ with respect to $\cdot_{\mathbb{N}}$. □

Theorem 5.55 (Distributive Law for $\mathbb{N}$). *The multiplication $\cdot_{\mathbb{N}}$ on the set of natural numbers is distributive over the addition $+_{\mathbb{N}}$ on $\mathbb{N}$.*

Proof. To demonstrate the distributivity of the binary operation $\cdot_{\mathbb{N}}$ over $+_{\mathbb{N}}$, we establish left-distributivity by verifying the universal sentence

$$\forall m, n, p\,(m, n, p \in \mathbb{N} \Rightarrow p \cdot_{\mathbb{N}} (m +_{\mathbb{N}} n) = (p \cdot_{\mathbb{N}} m) +_{\mathbb{N}} (p \cdot_{\mathbb{N}} n)). \tag{5.268}$$

We let m, n and p be arbitrary natural numbers, so that the sets

$$\begin{aligned} M &= \{1, \ldots, m\} \times \{0\}, \\ N &= \{1, \ldots, n\} \times \{1\}, \\ P &= \{1, \ldots, p\} \end{aligned}$$

have the cardinalities $|M| = m$, $|N| = n$ and $|P| = p$, according to (4.508) and (4.506). Furthermore, observing that (5.227) holds for the sets M and N, we may infer from this the truth of $M \cap N = \emptyset$. Next, we notice that the sum of m and n is determined by

$$m +_{\mathbb{N}} n = |M \cup N|,$$

according to (5.184). Thus, the conjunction

$$|P| = p \wedge |M \cup N| = m +_{\mathbb{N}} n$$

holds, which gives the product

$$\begin{aligned} p \cdot_{\mathbb{N}} (m +_{\mathbb{N}} n) &= |P \times (M \cup N)| \\ &= |(P \times M) \cup (P \times N)|, \end{aligned} \tag{5.269}$$

according to (5.240) and (3.56). As the conjunctions $|P| = p \wedge |M| = m$ and $|P| = p \wedge |N| = n$ are clearly true, the product of p and m and the product of p and n are determined by

$$\begin{aligned} p \cdot_{\mathbb{N}} m &= |P \times M|, \\ p \cdot_{\mathbb{N}} n &= |P \times N|, \end{aligned}$$

using again (5.240); regarding the Cartesian products occurring in these equations, the previously mentioned $M \cap N = \emptyset$ implies the disjointness of $(P \times M)$ and $(P \times N)$ with (3.55), so that the multiple conjunction

$$|P \times M| = p \cdot_{\mathbb{N}} m \wedge |P \times N| = p \cdot_{\mathbb{N}} n \wedge (P \times M) \cap (P \times N) = \emptyset$$

holds. Therefore, the sum of $p \cdot_{\mathbb{N}} m$ and $p \cdot_{\mathbb{N}} n$ is determined by

$$\begin{aligned} (p \cdot_{\mathbb{N}} m) +_{\mathbb{N}} (p \cdot_{\mathbb{N}} n) &= |(P \times M) \cup (P \times N)| \\ &= p \cdot_{\mathbb{N}} (m +_{\mathbb{N}} n), \end{aligned}$$

using (5.185) and then (5.269), proving the implication in (5.268). Since m, n and p were arbitrary, we may therefore conclude that (5.268) holds, so that $\cdot_{\mathbb{N}}$ is by definition left-distributive over $+_{\mathbb{N}}$. Since we already know that $\cdot_{\mathbb{N}}$ is commutative, it follows with Proposition 5.28 that $\cdot_{\mathbb{N}}$ is distributive over $+_{\mathbb{N}}$. □

Corollary 5.56. *The ordered triple* $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$ *is a commutative, nontrivial semiring.*

Proof. In light of Note 5.19, Note 5.21 and Theorem 5.55, we wee that $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$ is a commutative semiring. To show that this semiring is nontrivial, we recall Proposition 5.47 and prove $\mathbb{N} \neq \{0\}$ by contradiction, assuming the negation of that inequality to be true, so that $\mathbb{N} = \{0\}$ follows to be true with the Double Negation Law. Since $\mathbb{N}$ is a singleton, we obtain with (2.180) the uniquely existential sentence $\exists! n\,(n \in \mathbb{N})$, whose uniqueness part is given by

$$\forall n, n'([n \in \mathbb{N} \wedge n' \in \mathbb{N}] \Rightarrow n = n').$$

Therefore, $0 \in \mathbb{N}$ and $1 \in \mathbb{N}$ imply $0 = 1$, which contradicts the fact that $0 \neq 1$ holds according to (4.165). This completes the proof of $\mathbb{N} \neq \{0\}$, so that the semiring $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$ is indeed nontrivial. □

Theorem 5.57. *The semiring* $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$ *is zero-divisor free.*

Proof. Recalling from Proposition 5.47 that 0 is the zero element in $\mathbb{N}$, we apply the Criterion for zero-divisor freeness (5.175) and prove accordingly

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [(m \cdot_{\mathbb{N}} n = 0 \vee n \cdot_{\mathbb{N}} m = 0) \Rightarrow (m = 0 \vee n = 0)]). \quad (5.270)$$

For this purpose, we let $m, n \in \mathbb{N}$ be arbitrary and assume the disjunction $m \cdot_{\mathbb{N}} n = 0 \vee n \cdot_{\mathbb{N}} m = 0$ to be true. Based on this disjunction, we now prove the desired consequent $m = 0 \vee n = 0$ by cases.

In the first case $m \cdot_{\mathbb{N}} n = 0$, we observe in light of the Law of the Excluded Middle that the disjunction $m = 0 \vee m \neq 0$ holds and consider accordingly the two further subcases $m = 0$ and $m \neq 0$. On the one hand, if $m = 0$ holds, then the disjunction $m = 0 \vee n = 0$ to be proven is also true. On the other hand, if $m \neq 0$ holds, then the product of m and n (which is identical with 0 according to the current case assumption) is determined by

$$0 = m \cdot_{\mathbb{N}} n = |\{1, \ldots, m\} \times \{1, \ldots, n\}|,$$

applying (5.239). These equations imply

$$\{1, \ldots, m\} \times \{1, \ldots, n\} = \emptyset$$

with (4.527), using the evident fact that Cartesian product is a finite set. Then, the preceding equation implies with (3.27) that the disjunction

$$\{1, \ldots, m\} = \emptyset \vee \{1, \ldots, n\} = \emptyset$$

holds. Here, the subcase assumption $m \neq 0$ implies $\{1, \ldots, m\} \neq \emptyset$ by definition of an initial segment, so that the second part $\{1, \ldots, n\} = \emptyset$ of the preceding disjunction is true. This means in view of (4.239) that $n = 0$ holds, and therefore the desired disjunction $m = 0 \vee n = 0$ follows again to be true. We thus showed in the first case that $m \cdot_{\mathbb{N}} n = 0$ implies the truth of $m = 0 \vee n = 0$.

In the other case that $n \cdot_{\mathbb{N}} m = 0$ is true, we obtain

$$0 = n \cdot_{\mathbb{N}} m = m \cdot_{\mathbb{N}} n$$

with the Commutative Law for the multiplication on $\mathbb{N}$. These equations give $m \cdot_{\mathbb{N}} n = 0$, which then implies $m = 0 \vee n = 0$ as shown in the proof for the first case.

This completes the proof of the implication in (5.270), and since m and n were arbitrary, we may therefore conclude that (5.270) is true. This universal sentence in turn implies with the Criterion for zero-divisor freeness that the semiring $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$ has no zero divisors, as claimed. $\square$

5.4. Ordered Elementary Domains $(X, +, \cdot, <)$

Definition 5.18 (Ordered elementary domain). For any set X, any addition $+$ on X, any multiplication $\cdot$ on X and any binary relation $<$, we say that the ordered quadruple

$$(X, +, \cdot, <) \tag{5.271}$$

is an *ordered elementary domain* iff

1. the zero element 0_X exists,
2. the unity element 1_X exists,
3. $(X, +, \cdot)$ is a nontrivial semiring,
4. $(X, +, \cdot)$ is a commutative semiring,
5. $(X, +, \cdot)$ is zero-divisor free,
6. $<$ is comparable, and
7. $<$ satisfies

$$\forall a, b\, (a, b \in X \Rightarrow [a < b \Leftrightarrow \exists d\, (d \in X \,\wedge\, d \neq 0_X \,\wedge\, a + d = b)]), \tag{5.272}$$

The following example shows that it is not a trivial task to find an example of an ordered elementary domain. It will in fact be the purpose of the subsequent Chapter 5 to accomplish this task.

Proposition 5.58. *For any x and any y satisfying $x \neq y$ it is true that*

$$\begin{aligned}&(\{x, y\},\\ &\ \{((x, x), x), ((x, y), y), ((y, x), y), ((y, y), y)\},\\ &\ \{((x, x), x), ((x, y), x), ((y, x), x), ((y, y), y)\},\\ &\ \{(x, y)\})\end{aligned} \tag{5.273}$$

satisfies all of the properties of an ordered elementary domain except for Property 7.

Proof. Letting x and y be arbitrary and assuming $x \neq y$ to be true, we have that

1. the zero element 0_X of $X = \{x, y\}$ with respect to the join/addition $\sqcup$ on $\{x, y\}$ exists according to Corollary 5.16a),

2. the unity element 1_X of $X = \{x, y\}$ with respect to the meet/multiplication $\sqcap$ on $\{x, y\}$ exists according to Corollary 5.16b),
3. $(X, \sqcup, \sqcap)$ is a nontrivial semiring in view of Corollary 5.41,
4. $(X, \sqcup, \sqcap)$ is a commutative semiring because of Corollary 5.38,
5. the semiring $(X, \sqcup, \sqcap)$ is zero-divisor free due to Proposition 5.45,
6. $<= \{(x, y)\}$ is a comparable binary relation on $X = \{x, y\}$ as shown in Proposition 3.50.

To verify that (5.273) does not satisfy Property 7 of an ordered elementary domain, we prove the negation of (5.272) by contradiction, assuming the double negation of (5.272) to be true. To do this, we apply the Double Negation Law, so that (5.272) follows to be true. We therefore have in particular for the elements $a = y$ and $b = y$ in $\{x, y\}$ that the equivalence

$$y < y \Leftrightarrow \exists d\,(d \in \{x, y\} \,\wedge\, d \neq 0_X \,\wedge\, y \sqcup d = y) \tag{5.274}$$

holds, so that the inequality $y < y$ and the existential sentence take identical truth values. Let us now observe on the one hand that the initial assumption $y \neq x$ implies with the Equality Criterion for ordered pairs evidently $(y, y) \neq (x, y)$, which in turn implies $(y, y) \notin \{(x, y)\}$ $[=<]$ with (2.169), so that $\neg(y, y) \in <$ is true, which negation we may also write as $\neg y < y$. Thus, the left-hand side of the equivalence (5.274) is true. On the other hand, we may choose the element $d = y$ in $\{x, y\}$, which satisfies $d \neq 0_X$ $[= x]$ because of the initial assumption $y \neq x$. Furthermore, the definition of the join

$$\sqcup = \{((x, x), x), ((x, y), y), ((y, x), y), ((y, y), y)\}$$

shows in light of (2.244) that $((y, y), y) \in \sqcup$ holds, which we may also write as $y \sqcup y = y$, so that substitution yields the true equation $y \sqcup d = y$. Thus, the existential sentence in (5.274) is true, so that the two parts of the equivalence take different truth values. This finding contradicts the previously established statement that $y < y$ and the existential sentence take the same truth value. Consequently, we may infer from this that the equivalence in (5.272) does not hold for all elements $a, b \in \{x, y\}$, as required by Property 7 of an ordered elementary domain. $\square$

In the remainder of the current chapter, we establish some useful properties of ordered elementary domains, which are derived from the Properties 1 – 7.

Proposition 5.59. *For any ordered elementary domain* $(X, +, \cdot, <)$ *it is true that*

a) *every nonzero element of* X *is greater than the zero element, i.e.*

$$\forall a\,(a \in X \Rightarrow [a \neq 0_X \Leftrightarrow 0_X < a]). \tag{5.275}$$

b) *every element of* X *is greater than or equal to the zero element, i.e.*

$$\forall a\,(a \in X \Rightarrow [0_X < a \lor a = 0_X). \tag{5.276}$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets and assume that $(X, +, \cdot, <)$ is an ordered elementary domain.

Concerning a), we let $a \in X$ be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that $a \neq 0_X$ holds. Then, the assumption $a \in X$ implies the truth of the equation $0_X + a = a$ with the definition of the zero element. In view of the preceding assumptions and this equation, we thus see that the existential sentence

$$\exists d\,(d \in X \land d \neq 0_X \land 0_X + d = a)$$

holds, so that $0_X < a$ follows to be true with Property 7 of an ordered elementary domain. This completes the proof of the first part of the equivalence in (5.275).

To prove the second part ('$\Leftarrow$'), we now assume $0_X < a$, which implies that $0_X = a$ is false because of Property 6 of an ordered elementary domain in connection with the Characterization of comparability. Thus, $a \neq 0_X$ is true, which completes the proof of the equivalence, and therefore also the proof of the implication in (5.275).

As a is arbitrary, we may therefore conclude that the universal sentence (5.275) holds.

Concerning b), we let a again be arbitrary, and we now prove the implication by cases, considering the two exhaustive cases $a = 0_X$ and $a \neq 0_X$. In the first case, we assume accordingly that $a \in X$ and $a = 0_X$ are true. The latter equation then evidently implies the truth of the disjunction $0_X < a \lor a = 0_X$. In the second case, we now assume the conjunction of $a \in X$ and $a \neq 0_X$ to be true, which assumptions imply $0_X < a$ with (5.275). Consequently, the disjunction $0_X < a \lor 0_X = a$ is also true, so that the proof of the implication in (5.276) by cases is complete. Since a is arbitrary, the universal sentence (5.276) follows then to be true.

As X, $+$, $\cdot$ and $<$ were arbitrary sets, we may now conclude that the proposition holds. $\square$

Corollary 5.60. *For any ordered elementary domain* $(X, +, \cdot, <)$ *and any element* a *in* X*, it is false that* a *is less than* 0_X*, i.e.*

$$\forall a\,(a \in X \Rightarrow \neg a < 0_X). \tag{5.277}$$

Proof. Letting X, $+$, $\cdot$ and $<$ be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain and letting a be an arbitrary element of X, it follows with (5.276) that the disjunction $0_X < a \vee a = 0_X$ is true, which we may now use to prove the desired negation $\neg a < 0_X$ by cases. In case that $0_X < a$ holds, it follows with the comparability of $<$ (according to Property 6 of an ordered elementary domain) that $a < 0_X$ is false, so that the negation $\neg a < 0_X$ is true. In case that the second part $a = 0_X$ of the preceding disjunction holds, it follows with the comparability of $<$ that $a < 0_X$ is false, and therefore $\neg a < 0_X$ is true again. We thus proved that $a \in X$ implies $\neg a < 0_X$, and as a is arbitrary, we may therefore conclude that (5.277) holds. Since X, $+$, $\cdot$ and $<$ were also arbitrary, we may then further conclude that the corollary is true. □

Note 5.22. We will refer to the property (5.277) of an ordered elementary domain $(X, +, \cdot, <)$ also as the *nonnegativity* of the elements of X, and we say accordingly that the elements of X are *nonnegative*. In doing so, we anticipate the existence of 'negative' elements, which will be defined in the second part on numerical measurement data.

Corollary 5.61. *For any ordered elementary domain* $(X, +, \cdot, <)$ *it is true that the sum of a nonzero element of* X *and any element of* X *is nonzero, i.e.*

$$\forall a, b\,(a, b \in X \Rightarrow [a \neq 0_X \Rightarrow a + b \neq 0_X]). \tag{5.278}$$

Proof. Letting X, $+$, $\cdot$ and $<$ be arbitrary sets such that $(X, +, \cdot, <)$ is an ordered elementary domain (with zero element 0_X) and letting then a and b be arbitrary elements of X, we may prove the implication by contradiction, assuming $a \neq 0_X$ and $\neg a + b \neq 0_X$ to be true. To begin with, the latter negation implies $a + b = 0_X$ with the Double Negation Law. Since $b + a = a + b\ (= 0_X)$ holds due to the commutativity of the addition $+$ (according to Property 4 of an ordered elementary domain), we obtain the equation $b + a = 0_X$. Together with the initial assumptions $a \in X$ and $a \neq 0_X$, this shows that there exists a constant d which satisfies $d \in X$, $d \neq 0_X$ and $b + d = 0_X$. Consequently, Property 7 of an ordered elementary domain yields $b < 0_X$. Since $b \in X$ implies also the truth of $\neg b < 0_X$ with (5.277), we evidently obtained a contradiction, which finding proves the implication in (5.278). Since a and b are arbitrary, we may therefore conclude that the universal sentence (5.278) holds. Then, as the sets X, $+$, $\cdot$ and $<$ were also arbitrary, the corollary follows to be true. □

Theorem 5.62 (Linear ordering of ordered elementary domains). *For any ordered elementary domain $(X, +, \cdot, <)$ it is true that $<$ is a linear ordering of X.*

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets and assume that $(X, +, \cdot, <)$ is an ordered elementary domain. Since $<$ is a comparable binary relation according to Property 6 of an ordered elementary domain, it suffices in view of the Characterization of a linearly ordered set to prove that $<$ is transitive. For this purpose, we verify

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [(a < b \,\wedge\, b < c) \Rightarrow a < c]), \tag{5.279}$$

letting $a, b, c \in X$ be arbitrary and assuming $a < b \,\wedge\, b < c$ to be true. On the one hand, $a < b$ implies with (5.272) that there exists an element of X, say $\bar{d}$, with $\bar{d} \neq 0_X$ and $a + \bar{d} = b$. On the other hand, $b < c$ implies – again with (5.272) – that there is an element of X, say $\bar{\bar{d}}$, such that $\bar{\bar{d}} \neq 0_X$ and $b + \bar{\bar{d}} = c$ hold. The previous two equations then yield (by substitution)

$$c = b + \bar{\bar{d}} = (a + \bar{d}) + \bar{\bar{d}},$$

and therefore

$$a + (\bar{d} + \bar{\bar{d}}) = c, \tag{5.280}$$

utilizing the associativity of the addition $+$. Here, we notice that

$$\bar{d} + \bar{\bar{d}} \in X \tag{5.281}$$

holds as the addition $+$ is a binary operation on X. Furthermore, since $\bar{d}, \bar{\bar{d}} \in X$ and $\bar{d} \neq 0_X$ are both true, we obtain

$$\bar{d} + \bar{\bar{d}} \neq 0_X \tag{5.282}$$

with (5.278). The findings (5.280) – (5.282) show that the existential sentence

$$\exists d\,(d \in X \,\wedge\, d \neq 0_X \,\wedge\, a + d = c)$$

holds, so that the desired inequality $a < c$ follows to be true with (5.272). Since a, b and c are arbitrary, we may therefore conclude that (5.279) is true, which means that $<$ is indeed a transitive binary relation. Consequently, $<$ is a linear ordering of X according to Theorem 3.75, and since X, $+$, $\cdot$ and $<$ were initially arbitrary sets, we may infer from this that the theorem is indeed true. □

Note 5.23. From now on, we will treat $\leq$ as the total ordering of X induced by the linear ordering $<$ of X

Lemma 5.63. *The following sentences hold for any ordered elementary domain* $(X, +, \cdot, <)$.

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [a < b \Rightarrow a + c < b + c]), \tag{5.283}$$
$$\forall a, b, c\,(a, b, c \in X \Rightarrow [a \leq b \Rightarrow a + c \leq b + c]), \tag{5.284}$$
$$\forall a, b, c\,([a, b, c \in X \,\wedge\, 0_X < c] \Rightarrow [a < b \Rightarrow a \cdot c < b \cdot c]), \tag{5.285}$$
$$\forall a, b, c\,([a, b, c \in X \,\wedge\, 0_X < c] \Rightarrow [a \leq b \Rightarrow a \cdot c \leq b \cdot c]) \tag{5.286}$$

Proof. First we let X, $+$, $\cdot$ and $<$ be arbitrary sets and assume $(X, +, \cdot, <)$ to be an ordered elementary domain.

Regarding (5.283), we let a, b, c arbitrary elements of X and prove the implication $a < b \Rightarrow a + c < b + c$ directly, assuming that $a < b$ holds. This inequality implies with Property 7 of an ordered elementary domain that there exists a nonzero element in X, say $\bar{d} \neq 0_X$, satisfying $a + \bar{d} = b$. We then obtain the true equations

$$b + c = (a + \bar{d}) + c = a + (\bar{d} + c) = a + (c + \bar{d}) = (a + c) + \bar{d},$$

applying substitution, the associativity of the addition $+$ on X, the commutativity of the addition $+$ on X, and finally again the associativity of $+$. These equations yield $(a + c) + \bar{d} = b + c$, where $\bar{d} \in X$ and $\bar{d} \neq 0_X$ are also true, as stated before. We thus showed that there exists a constant d such that $d \in X$, $d \neq 0_X$ and $(a + c) + d = b + c$ hold, which existential sentence then implies the desired inequality $a + c < b + c$ with (5.272). Thus, the two implications in (5.283) are true, and as a, b, c were arbitrary, we may further conclude that the universal sentence (5.283) is true.

Regarding (5.284), we let a, b and c be arbitrary elements of X and assume $a \leq b$ to be true. According to Theorem 3.81b), the induced reflexive partial ordering $\leq$ satisfies the disjunction $a < b \,\vee\, a = b$, which we may now use to prove the sentence $a + c \leq b + c$ by cases. On the one hand, if $a < b$ holds, we obtain $a + c < b + c$ with (5.283); therefore, the disjunction $a + c < b + c \,\vee\, a + c = b + c$ is also true, so that $a + c \leq b + c$ holds by definition of the induced partial ordering $\leq$. On the other hand, if $a = b$ holds, then substitution evidently yields the equation $a + c = b + c$; consequently, the disjunction $a + c < b + c \,\vee\, a + c = b + c$ is again true, so that $a + c \leq b + c$ follows to be true as for the first case. This completes the proof by cases of $a + c \leq b + c$, and since a, b and c are arbitrary, we may therefore conclude that (5.284) holds.

Regarding (5.285), we let again $a, b, c \in X$ be arbitrary and assume first $0_X < c$ and then $a < b$ to be true. Let us observe here that the former inequality implies $0_X \neq c$ because of the comparability of the linear ordering

$<$ of X. Furthermore, the assumed inequality $a < b$ implies with (5.272) that there exists a constant, say $\bar{d}$, such that $\bar{d} \in X$, $\bar{d} \neq 0_X$ and $a + \bar{d} = b$ are true. We now obtain the equations

$$c \cdot b = c \cdot (a + \bar{d}) = (c \cdot a) + (c \cdot \bar{d})$$

by applying substitution and then the distributivity of $\cdot_X$ over $+_X$. In view of the commutativity of the multiplication $\cdot$, the preceding equations then give

$$(a \cdot c) + (\bar{d} \cdot c) = b \cdot c. \tag{5.287}$$

Here, we notice that

$$\bar{d} \cdot c \in X \tag{5.288}$$

holds because the multiplication is a binary operation on X. Now, since $\bar{d}, c \in X$ also holds and since the conjunction $\bar{d} \neq 0_X \wedge c \neq 0_X$ is also true, it follows with the Criterion for zero-divisor freeness (5.176) in particular that

$$\bar{d} \cdot c \neq 0_X \tag{5.289}$$

holds. Thus, (5.287) – (5.289) show that there is a d which satisfies $d \in X$, $d \neq 0_X$ and $(a \cdot c) + d = b \cdot c$, so that the desired inequality $a \cdot c < b \cdot c$ follows to be true with (5.272). As a, b and c are arbitrary, we may therefore conclude that (5.285) holds.

Since X, $+$, $\cdot$ and $<$ were arbitrary sets, we may finally conclude that the stated sentences are true for any such sets. $\square$

Exercise 5.32. Establish the universal sentence (5.286) for any ordered elementary domain $(X, +, \cdot, <)$.

(Hint: Proceed in analogy to the proof of (5.284).)

The implications in (5.283) – (5.286) linking the inequalities can be turned into equivalences.

Theorem 5.64 (Monotony Laws for ordered elementary domains). *The following laws hold for any ordered elementary domain* $(X, +, \cdot, <)$.

a) **Monotony Law for $+$ and $<$:**

$$\forall a, b, c\, (a, b, c \in X \Rightarrow [a < b \Leftrightarrow a + c < b + c]). \tag{5.290}$$

b) **Monotony Law for $+$ and $\leq$:**

$$\forall a, b, c\, (a, b, c \in X \Rightarrow [a \leq b \Leftrightarrow a + c \leq b + c]). \tag{5.291}$$

c) **Monotony Law for $\cdot$ and $<$***:*

$$\forall a, b, c\,([a, b, c \in X \,\wedge\, 0_X < c] \Rightarrow [a < b \Leftrightarrow a \cdot c < b \cdot c]). \quad (5.292)$$

d) **Monotony Law for $\cdot$ and $\leq$***:*

$$\forall a, b, c\,([a, b, c \in X \,\wedge\, 0_X < c] \Rightarrow [a \leq b \Leftrightarrow a \cdot c \leq b \cdot c]). \quad (5.293)$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain.

Concerning a), we let a, b and c be arbitrary elements of X and notice that the first part ('$\Rightarrow$') of the equivalence holds in view of (5.283). We now prove the second part ('$\Leftarrow$') by contradiction, assuming $a + c < b + c$ and $\neg a < b$ to be both true. Here, the negation $\neg b > a$ implies $b \leq a$ with the Negation Formula for $<$, using the fact that $<$ is a linear ordering of X according to Theorem 5.62. It then follows from this with (5.284) that $b + c \leq a + c$ holds, which we may write equivalently as $\neg a + c < b + c$ by using the Negation Formula for $<$. This finding contradicts the initially assumed $a+c < b+c$, so that the proof of the second part of the equivalence in (5.290) is complete. This in turn proves the implication in (5.290), and since a, b, c, X, $+$, $\cdot$ and $<$ were arbitrary, we may therefore conclude that the Monotony Law for $+$ and $<$ is true. □

Exercise 5.33. Prove for any ordered elementary domain $(X, +, \cdot, <)$

- the Monotony Law for $+$ and $\leq$,
- the Monotony Law for $\cdot$ and $<$ and
- the Monotony Law for $\cdot$ and $\leq$.

(Hint: Apply proofs by contradiction.)

Theorem 5.65 (Additivity of inequalities). *The following laws hold for any ordered elementary domain $(X, +, \cdot, <)$.*

a) **Additivity of $<$-inequalities***:*

$$\forall a, b, c, d\,(a, b, c, d \in X \Rightarrow [(a < b \wedge c < d) \Rightarrow a+c < b+d]). \quad (5.294)$$

b) **Additivity of $\leq$-inequalities***:*

$$\forall a, b, c, d\,(a, b, c, d \in X \Rightarrow [(a \leq b \wedge b \leq d) \Rightarrow a+c \leq b+d]). \quad (5.295)$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets such that $(X, +, \cdot, <)$ is an ordered elementary domain. We then let a, b, c and d be arbitrary and assume $a, b, c, d \in X$ to be true. Next, we assume the inequalities $a < b$ and $c < d$ to be both true, which imply respectively

$$\begin{aligned} a + c &< b + c, \\ c + b &< d + b \end{aligned} \tag{5.296}$$

with the Monotony Law for $+$ and $<$. We may write the latter also as

$$b + c < b + d \tag{5.297}$$

by applying the commutativity of the addition on X. Thus, the conjunction of (5.296) and (5.297) holds, which now implies the desired $a + c < b + d$ with the transitivity of the linear ordering $<$ of X. Thus, the proof of the second implication in (5.294) is complete, which in turn proves the implication based on the antecedent $a, b, c, d \in X$. Since a, b, c and d are arbitrary, we may therefore conclude that the universal sentence (5.294) is true. Then, as X, $+$, $\cdot$ and $<$ were initially arbitrary sets, we may infer from this finding the truth of Part a) of the stated theorem. □

Exercise 5.34. Prove Part b) of Theorem 5.65.

Theorem 5.66 (Cancellation Laws for ordered elementary domains). *The following laws are true for any ordered elementary domain* $(X, +, \cdot, <)$.

a) **Cancellation Law for $+$***:*

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [a + b = a + c \Rightarrow b = c]). \tag{5.298}$$

b) **Cancellation Law for $\cdot$***:*

$$\forall a, b, c\,([a, b, c \in X \,\wedge\, a \neq 0_X] \Rightarrow [a \cdot b = a \cdot c \Rightarrow b = c]). \tag{5.299}$$

c) **Cancellation Law for $\mathbf{0_X}$***:*

$$\forall a\,(a \in X \Rightarrow [a \cdot 0_X = 0_X \,\wedge\, 0_X \cdot a = 0_X]). \tag{5.300}$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary and assume $(X, +, \cdot, <)$ to be an ordered elementary domain.

Concerning b), we take arbitrary $a, b, c \in X$ such that $a \neq 0_X$ holds, and we prove the implication $a \cdot b = a \cdot c \Rightarrow b = c$ by contradiction, assuming $a \cdot b = a \cdot c$ and $b \neq c$ to be both true. Let us now first observe that the assumption $a \neq 0_X$ implies $0_X < a$ with (5.275). Since $<$ is comparable, the assumed inequality $b \neq c$ implies that $b < c$ or $b > c$ is true. In case $b < c$ holds, the Monotony Law for $\cdot$ and $<$ gives in view of the assumption $a \neq 0$ the inequality $b \cdot a < c \cdot a$, and therefore $a \cdot b < a \cdot c$ with the commutativity of $\cdot$. Thus, $a \cdot b < a \cdot c$ and $a \cdot b = a \cdot c$ are both true, which contradicts the fact that the conjunction of $a \cdot b < a \cdot c$ and $a \cdot b = a \cdot c$ is false because of the comparability of $<$. Similarly, the case of $b > c$ implies $c \cdot a < b \cdot a$ and therefore $a \cdot c < a \cdot b$, which yields again a contradiction with the initial assumption $a \cdot c = a \cdot b$. Thus, the proof of the implications is complete, and since a, b and c are arbitrary, the proposed law (5.299) follows then to be true.

Concerning c), we let a be arbitrary in X and observe the truth of the equations

$$\begin{aligned}(a \cdot 0_X) + (a \cdot 0_X) &= a \cdot (0_X + 0_X) \\ &= a \cdot 0_X \\ &= (a \cdot 0_X) + 0_X,\end{aligned}$$

using the distributivity of $\cdot_X$ over $+_X$ and then the definition of the zero element (which is applied twice). We now see in light of the Cancellation Law for $+$ that the resulting equation

$$(a \cdot 0_X) + (a \cdot 0_X) = (a \cdot 0_X) + 0_X$$

implies $a \cdot 0_X = 0_X$, which proves the first part of the conjunction in (5.300). Using the same arguments, we obtain also

$$\begin{aligned}(0_X \cdot a) + (0_X \cdot a) &= (0_X + 0_X) \cdot a \\ &= 0_X \cdot a \\ &= (0_X \cdot a) + 0_X,\end{aligned}$$

and therefore $0_X \cdot a = 0_X$, so that the second part of the conjunction to be proven also holds. Thus, the proof of the implication in (5.300) is complete, and as a is arbitrary, the Cancellation Law for 0_X follows also to be true.

Since X, $+$, $\cdot$ and $<$ were arbitrary sets, we may finally conclude that the stated sentences are true for any such sets. □

Exercise 5.35. Prove for any ordered elementary domain $(X, +, \cdot, <)$ the Cancellation Law for $+$.

(Hint: Proceed in analogy to the proof of the Cancellation Law for $\cdot$.)

We now investigate a few useful consequences of the Cancellation Laws.

Proposition 5.67. *For any ordered elementary domain $(X,+,\cdot,<)$ it is true that, if an element b of X is the sum of two elements a and d of X, then b is greater than or equal to a, i.e.*

$$\forall a,b,d\,([a,b,d \in X \,\wedge\, a+d=b] \Rightarrow a \leq b). \tag{5.301}$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets such that $(X,+,\cdot,<)$ is an ordered elementary domain, we let a, b and d also be arbitrary, and we prove the implication by contradiction, assuming $a,b,d \in X$, the equation $a+d=b$ and the negation $\neg a \leq b$ to be true. Since $<$ is a linear ordering of X according to Theorem 5.62 and since $\leq$ is the induced total ordering of X, we may apply the Negation Formula for $\leq$ to infer from $\neg a \leq b$ the truth of $b < a$. In view of Property 7 of an ordered elementary domain, there then exists a constant, say $\bar{e}$, such that $\bar{e} \in X$, $\bar{e} \neq 0_X$ and $b+\bar{e}=a$ hold. Next, we may apply substitution based on this equation to obtain from $a+d=b$ the equation $(b+\bar{e})+d=b$, which we may also write as

$$b+(\bar{e}+d)=b+0$$

utilizing the associativity of the addition and the definition of a neutral element. Then, the Cancellation Law for $+$ yields $\bar{e}+d=0$. Since $\bar{e} \neq 0_X$ implies also $\bar{e}+d \neq 0$ with (5.278), we evidently obtained a contradiction, so that the proof of the implication in (5.301) is complete. Because a, b, d, X, $+$, $\cdot$ and $<$ were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Theorem 5.68 (Distinctness of the zero element and the unity element in ordered elementary domains). *For any ordered elementary domain $(X,+,\cdot,<)$ it is true that the zero and the unity element are distinct elements of X, i.e.*

$$0_X \neq 1_X. \tag{5.302}$$

Proof. Letting X, $+$, $\cdot$ and $<$ be arbitrary sets such that $(X,+,\cdot,<)$ is an ordered elementary domain, we prove the proposed inequality $0_X \neq 1_X$ by contradiction, assuming $\neg 0_X \neq 1_X$ to be true, which assumption we may write equivalently as $0_X = 1_X$ by applying the Double Negation Law. We now show that these assumptions imply $X = \{0_X\}$, which we may write equivalently as

$$\forall a\,(a \in X \Leftrightarrow a \in \{0_X\}), \tag{5.303}$$

using (2.18). We let a be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $a \in X$ to be true. We then obtain the true equations

$$a = a \cdot 1_X = a \cdot 0_X = 0_X$$

by applying the definition of the unity element, then substitution based on the initial assumption $0_X = 1_X$, and finally the Cancellation Law for 0_X. These equations give $a = 0_X$ and therefore $a \in \{0_X\}$ due to (2.169), proving the first part of the equivalence. To prove the second part ('$\Leftarrow$'), we now assume that $a \in \{0_X\}$ holds, so that evidently $a = 0_X$. Since $0_X \in X$ is also true by definition of the zero element, we obtain the desired $a \in X$ via substitution. This completes the proof of the equivalence in (5.303), and since a is arbitrary, we may therefore conclude that the universal sentence (5.303) holds. It then follows with (2.18) that $X = \{0_X\}$ is true, in contradiction to the (nontriviality) Property 3 of an ordered elementary domain, which states that $X \neq \{0_X\}$ holds. This completes the proof of the inequality $0_X \neq 1_X$, and as X, $+$, $\cdot$ and $<$ were arbitrary, we may therefore conclude that the theorem holds. □

Thus, Proposition 5.59a) gives then immediately the following inequality between 0_X and 1_X.

Corollary 5.69. *For any ordered elementary domain* $(X, +, \cdot, <)$, *it is true that the zero element is less than the unity element of* X, *i.e.*

$$0_X < 1_X. \tag{5.304}$$

The Cancellation Law for 0_X also allows us to drop the condition imposed on the element c in the law (5.286).

Proposition 5.70. *The following sentence is true for any ordered elementary domain* $(X, +, \cdot, <)$.

$$\forall a, b, c\,(a, b, c \in X \Rightarrow [a \leq b \Rightarrow a \cdot c \leq b \cdot c]). \tag{5.305}$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets and assume $(X, +, \cdot, <)$ to be an ordered elementary domain. Furthermore, we let a, b, c be arbitrary elements of X. Here, $c \in X$ implies the truth of the disjunction $0_X < c \vee c = 0_X$ with (5.276), which we now apply to prove $a \cdot c \leq b \cdot c$ by cases. If the first part $0_X < c$ holds, then the implication in (5.305) follows to be true with (5.286). If the second part $c = 0_X$ holds, then we may prove the second implication in (5.305) directly. Assuming $a \leq b$, we obtain

$$a \cdot c = a \cdot 0_X = 0_X,$$
$$b \cdot c = b \cdot 0_X = 0_X$$

by applying substitution based on the case assumption $c = 0_X$ and then the Cancellation Law for 0_X. Consequently, these equations yield $a \cdot c = b \cdot c$ again by substitution. Then, the disjunction

$$a \cdot c < b \cdot c \vee a \cdot c = b \cdot c$$

is also true. Since the induced total ordering $\leq$ satisfies (3.238), the inequality $a \cdot c \leq b \cdot c$ is true, so that the proof of the second implication in (5.305) is complete. This in turn proves the implication based on the antecedent $a, b, c \in X$, and since a, b and c are arbitrary, we may further conclude that (5.305) holds. Then, as the sets X, $+$, $\cdot$ and $<$ were also arbitrary, the proposed sentence follows to be true. □

Property 7 (5.272) of an ordered elementary domain can be strengthened to guarantee unique existence of the element d satisfying $a + d = b$ in case of $a \leq b$.

Proposition 5.71. *For any ordered elementary domain $(X, +, \cdot, <)$ and any elements a, b in X such that a is less than or equal to b, it is true that there exists a unique d in X which satisfies $a + d = b$, i.e.*

$$\forall a, b\, (a, b \in X \Rightarrow [a \leq b \Rightarrow \exists! d\, (d \in X \,\wedge\, a + d = b)]). \tag{5.306}$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets such that $(X, +, \cdot, <)$ is an ordered elementary domain, we let a, b be arbitrary elements of X, and we assume $a \leq b$ to be true. Because the induced reflexive partial ordering $\leq$ of X satisfies (3.238), we have that the disjunction $a < b \vee a = b$ is true, which we now use to prove the existential part by cases. In case of $a < b$, there is some d satisfying $d \in X$ and $a + d = b$ due to Property 7 of an ordered elementary domain. In the other case of $a = b$, the choice $d = 0$ yields the true equation $a + 0_X = a$ with the definition of the zero element. To prove the uniqueness part, let d and d' be arbitrary such that $d \in X$, $a + d = b$, $d' \in X$ and $a + d' = b$ hold. The two equations give $a + d = a + d'$ via substitution, and the Cancellation Law for $+$ then yields $d = d'$, which finding establishes the uniqueness part. Thus, the uniquely existential sentence in (5.306), and as a and b are arbitrary, we may therefore conclude that the universal sentence (5.306) holds. Since X, $+$, $\cdot$ and $<$ were initially arbitrary sets, we may then further conclude that the proposition holds, as claimed. □

Definition 5.19 (Difference). We say for any ordered elementary domain $(X, +, \cdot, <)$ and any $a, b \in X$ with $a \leq b$ that an element d in X is the *difference* of b and a, symbolically

$$d = b - a, \tag{5.307}$$

iff $a + d = b$ holds.

Note 5.24. Whenever we are given an equation $a + d = b$, the difference $d = b - a$ is defined, because the given equation implies the required inequality $a \leq b$ with Proposition 5.67.

This definition yields because of the commutativity of + immediately the following result.

Corollary 5.72. *The following sentence holds for any ordered elementary domain* $(X, +, \cdot, <)$.

$$\forall a, b\,([a, b \in X \ \wedge\ a \leq b] \Rightarrow [b - a] + a = b). \tag{5.308}$$

Note 5.25. As the difference is not defined for all a and b in X (the difference is not defined for constants a, b with $a > b$), we cannot define a corresponding binary operation on X. To do this, we will extend the ordered elementary domain to an 'ordered integral domain' in the part on numerical measurement data.

Since the neutral element 0_X with respect to the addition in an ordered elementary domain satisfies $a + 0_X = a$ uniquely for any element a, we see that 0_X is the difference of identical elements.

Corollary 5.73. *For any ordered elementary domain* $(X, +, \cdot, <)$, *it is true that the difference of any element* $a \in X$ *and itself is identical with the zero element* 0_X, *i.e.*

$$\forall a\,(a \in X \Rightarrow a - a = 0_X). \tag{5.309}$$

Exercise 5.36. Verify the following sentence for any ordered elementary domain $(X, +, \cdot, <)$.

$$\forall a, b\,(a, b \in X \Rightarrow [b + a] - a = b). \tag{5.310}$$

(Hint: Establish first $a \leq b + a$ and $a + b = b + a$ for arbitrary $a, b \in X$.)

Returning to the 'restricted' Definition 5.19 of the difference, we now see with the help of the following lemma that the difference is distributive in a certain sense.

Lemma 5.74. *The following law holds for any ordered elementary domain* $(X, +, \cdot, <)$.

$$\forall a, b, c\,([a, b, c \in X \ \wedge\ c \leq a \ \wedge\ b \leq c] \Rightarrow [a - b] + [b - c] = a - c) \tag{5.311}$$

Proof. We take arbitrary sets X, $+$, $\cdot$, $<$ and assume that $(X, +, \cdot, <)$ is an ordered elementary domain. Then, we take arbitrary constants a, b, c and assume $a, b, c \in X$, $b \leq a$ and $c \leq b$ to hold. Because of Proposition 5.71, there exist a unique d satisfying $b + d = a$ (so that $d = a - b$) and a unique e satisfying $c + e = b$ (so that $e = b - c$). Substitutions now give the equations

$$a = b + d = (c + e) + [a - b] = (c + [b - c]) + [a - b],$$

which yield with the associativity and commutativity of the addition $+$

$$a = c + ([b - c] + [a - b]) = c + ([a - b] + [b - c]),$$

and therefore

$$c + ([a - b] + [b - c]) = a.$$

Since the assumed $c \leq b \wedge b \leq a$ implies $c \leq a$ with the transitivity of the induced total ordering $\leq$ of X, we may apply the definition of a difference and write $[a - b] + [b - c] = a - c$, as desired. As a, b and c are arbitrary, we may therefore conclude that (5.311) is true. Because X, $+$, $\cdot$ and $<$ were initially also arbitrary, we may now infer from this the truth of the lemma. $\square$

Corollary 5.75. *The following law holds for any ordered elementary domain* $(X, +, \cdot, <)$*.*

$$\forall a, b, c\,([a, b, c \in X \;\wedge\; c \leq a \;\wedge\; b \leq c] \Rightarrow [a - c] - [a - b] = b - c) \quad (5.312)$$

Proof. Letting X, $+$, $\cdot$, $<$, a, b and c be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain and such that $a, b, c \in X$ as well as the inequalities $c \leq a$ and $b \leq c$ hold, we first obtain the equation $[a - b] + [b - c] = a - c$ with (5.311). In view of Note 5.24, the difference $b - c = [a - c] - [a - b]$ is then defined, which equation proves the implication in (5.312). Since X, $+$, $\cdot$, $<$, a, b and c are arbitrary, we may therefore conclude that the corollary holds. $\square$

Exercise 5.37. Show for any ordered elementary domain $(X, +, \cdot, <)$ that any element in X is identical with the difference of itself and the zero element of X, i.e.

$$\forall a\,(a \in X \Rightarrow a = a - 0_X). \quad (5.313)$$

(Hint: Use (5.276), (3.238) and (5.90) with respect to $+$.)

Theorem 5.76 (Distributive Law for differences in ordered elementary domains). *The following sentence is true for any ordered elementary domain* $(X, +, \cdot, <)$*.*

$$\forall a, b, f\;([a, b, f \in X \;\wedge\; b \leq a] \Rightarrow f \cdot [a - b] = f \cdot a - f \cdot b) \quad (5.314)$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary, assume that $(X, +, \cdot, <)$ is an ordered elementary domain, let a, b, c also be arbitrary, and assume moreover that $a, b, f \in X$ and $b \leq a$ are true. Then, we obtain the true equations

$$\begin{aligned} f \cdot b + f \cdot [a - b] &= f \cdot (b + [a - b]) \\ &= f \cdot ([a - b] + b) \\ &= f \cdot ([a - b] + [b - 0_X]) \\ &= f \cdot (a - 0_X) \\ &= f \cdot a. \end{aligned} \tag{5.315}$$

by using the distributivity of $\cdot$ over $+$, the commutativity of $+$, (5.313), then Lemma (5.74), and finally again (5.313). Let us observe now that the assume $b \leq a$ implies $b \cdot f \leq a \cdot f$ with (5.305), which inequality we may also write as $f \cdot b \leq f \cdot a$ because of the commutativity of $\cdot$. Consequently, we may apply the definition of a difference to the equation (5.315) to obtain the desired equation in (5.314). Since a, b, f, X, $+$, $\cdot$ and $<$ were arbitrary, it follows from this finding that the theorem holds indeed. □

Theorem 5.77 (Monotony Laws for the difference in ordered elementary domains). *The following laws hold for any ordered elementary domain* $(X, +, \cdot, <)$.

a) **Monotony Law for $-$ and $<$:**

$$\forall a, b, c\,([a, b, c \in X \;\wedge\; c \leq a] \Rightarrow [a < b \Rightarrow a - c < b - c]). \tag{5.316}$$

b) **Monotony Law for $-$ and $\leq$:**

$$\forall a, b, c\,([a, b, c \in X \;\wedge\; c \leq a] \Rightarrow [a \leq b \Rightarrow a - c \leq b - c]). \tag{5.317}$$

Proof. We let X, $+$, $\cdot$, $<$, a, b and c be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain and such that the conjunction of $a, b, c \in X$ and $c \leq a$ is true; thus, the difference $a - c$ is defined. We now prove the implication

$$a < b \Rightarrow a - c < b - c \tag{5.318}$$

by contradiction, assuming $a < b$ and the negation $\neg a - c < b - c$ to be both true. Here, $a < b$ implies the truth of the disjunction $a < b \vee a = b$, which we may also write as $a \leq b$, because the induced total ordering $\leq$ of X satisfies (3.238). Then, since $c \leq a$ and $a \leq b$ are both true, we obtain $c \leq b$ with the transitivity of $\leq$, so that the difference $b - c$ is indeed defined. Furthermore, the assumed negation $\neg a - c < b - c$ implies $b - c \leq a - c$ with the Negation Formula for $<$, and this inequality further implies $(b - c) + c \leq (a - c) + c$ with the Monotony Law for $+$ and $\leq$. In view of (5.308), we have the equations $(b - c) + c = b$ and $(a - c) + c = a$, so that the preceding inequality becomes $b \leq a$, which in turn implies $\neg a < b$ with the Negation Formula for $<$. This finding is in contradiction to the assumption $a < b$, so that the proof of the implication (5.318) is complete. Since X, $+$, $\cdot$, $<$, a, b and c were initially arbitrary, we may therefore conclude that the Monotony Law for $-$ and $<$ holds indeed. □

Exercise 5.38. Prove the Monotony Law for $-$ and $\leq$.

(Hint: Proceed in analogy to the proof of the Monotony Law for $-$ and $<$, using Theorem 3.77a) and Theorem 5.64a).)

Corollary 5.78. *For any ordered elementary domain* $(X, +, \cdot, <)$ *and any elements* a, b *in* X*, it is true that, if* a *is less than* b*, then the difference of* b *and* a *is greater than the zero element, i.e.*

$$\forall a, b\,(a, b \in X \Rightarrow [a < b \Rightarrow b - a > 0_X]). \tag{5.319}$$

Proof. Letting X, $+$, $\cdot$, $<$, a and b be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain and such that a and b are elements of X, we now assume $a < b$ to be true. Since the induced total ordering $\leq$ of X is reflexive, the inequality $a \leq a$ also holds, so that we may apply the Monotony Law for $-$ and $<$ to infer from $a < b$ the truth of $a - a < b - a$. Here, $a - a = 0_X$ is true because of (5.309), so that substitution yields the inequality $0_X < b - a$, and thus the desired consequent $b - a > 0_X$. As X, $+$, $\cdot$, $<$, a and b were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Exercise 5.39. Establish the following laws for any ordered elementary domain $(X, +, \cdot, <)$.

$$\forall a, b, c\,([a, b, c \in X \wedge a \leq b] \Rightarrow [c \leq a \Rightarrow b - a \leq b - c]), \tag{5.320}$$

$$\forall a, b, c\,([a, b, c \in X \wedge a \leq b] \Rightarrow [c < a \Rightarrow b - a < b - c]). \tag{5.321}$$

(Hint: Apply similar arguments as in the proofs of the preceding Monotony Laws for the difference and apply in addition the commutativity and associativity of $+$.)

Proposition 5.79. *For any ordered elementary domain* $(X, +, \cdot, <)$*, it is true that subtracting two elements* b *and* c *of* X *successively from an element* a *of* X *gives the same result as subtracting the sum of* b *and* c *from* a*, given that this sum is less than or equal to* a*, i.e.*

$$\forall a, b, c\,([a, b, c \in X \wedge b + c \leq a] \Rightarrow (a - b) - c = a - (b + c)). \tag{5.322}$$

Proof. We take arbitrary sets X, $+$, $\cdot$, $<$, a, b and c, assuming $(X,+,\cdot,<)$ to be an ordered elementary domain, assuming a ,b, and c to be elements in X, and assuming the inequality $b+c \leq a$ to hold. Thus, the difference $a-(b+c)$ is defined, and we may now prove that the differences $a-b$ and $(a-b)-c$ are also specified.

For this purpose, we prove first the inequality $b \leq a$ by contradiction, assuming its negation to be true, so that $a < b$ holds according to the Negation Formula for $\leq$. Since $0_X \leq c$ follows also to be true with (5.276) and the Characterization of an induced reflexive partial ordering, we obtain with the Monotony Law for $+$ and $\leq$ the inequality $0_X + b \leq c + b$, which implies $b \leq b + c$ with the definition of the zero element and with the commutativity of the addition. In conjunction with the previously established $a < b$, this further implies $a < b + c$ with the Transitivity Formula for $<$ and $\leq$, and the Negation Formula for $\leq$ gives us then $\neg b + c \leq a$. Because $b+c \leq a$ is also true (by assumption), we arrived at a contradiction, so that the proof of $b \leq a$ is now complete; thus, the difference $a-b$ is defined.

Next, we may establish also the inequality $c \leq a - b$ by contradiction, assuming that its negation holds, so that $a - b < c$ follows to be true with the Negation Formula for $\leq$. Then, the Monotony Law for $+$ and $<$ yields $(a-b)+b < c+b$, which in turn implies $a < b + c$ with (5.308) and the commutativity of the addition. Consequently, $\neg b + c \leq a$ turns out to be true because of the Negation Formula for $\leq$, which contradicts again the initial assumption $b+c \leq a$. Having thus completed the proof of $c \leq a - b$, we may infer from this that the difference $(a-b)-c$ is also defined.

Let us observe now the truth of the equations

$$(a-b)-c = (a-b)-c \quad \wedge \quad a-(b+c) = a-(b+c),$$

which imply by definition of a difference

$$c + [(a-b)-c] = a-b, \tag{5.323}$$

$$(b+c) + [a-(b+c)] = a. \tag{5.324}$$

We obtain then the true equations

$$\begin{aligned}(b+c) + [(a-b)-c] &= (c + [(a-b)-c]) + b \\ &= (a-b)+b \\ &= a \\ &= (b+c) + [a-(b+c)]\end{aligned}$$

using the associativity and commutativity of the addition, (5.323), (5.308) and (5.324). Now, the Cancellation Law for $+$ gives us the equation $(a-b)-c = a-(b+c)$, so that the implication in (5.322) is true. As X, $+$, $\cdot$, $<$, a, b and c were arbitrary, we conclude that the proposition holds. $\square$

5.5. The Ordered Elementary Domain $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$

We finally arrive at the main result of the first part of the current exposition.

Theorem 5.80. *The ordered quadruple* $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$ *constitutes an ordered elementary domain with zero element* 0 *and unity element* 1*.*

Proof. We begin with the observation that the Properties 1 – 5 of an ordered elementary domain are satisfied by the semiring $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}})$in view of Proposition 5.47, Proposition 5.54, Corollary 5.56, and Theorem 5.57. Furthermore, Property 6 is also satisfied by the standard linear ordering $<_{\mathbb{N}}$ according to Corollary 4.21 and Theorem 3.75.

It therefore only remains fur us to verify Property 7 of an ordered elementary domain. For this purpose, we prove

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m <_{\mathbb{N}} n \Leftrightarrow \exists d\,(d \in \mathbb{N} \wedge d \neq 0 \wedge m +_{\mathbb{N}} d = n)]). \quad (5.325)$$

We let m and n be arbitrary natural numbers and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $m <_{\mathbb{N}} n$ to be true. Here, the assumed $n \in \mathbb{N}$ implies $n = 0 \vee n \in \mathbb{N}_+$ with (2.310). We may now prove by contradiction that the first part $n = 0$ of this disjunction is false. Indeed, assuming $n = 0$ to be true, the initial assumption $m <_{\mathbb{N}} n$ gives $m <_{\mathbb{N}} 0$, in contradiction to the fact that $m \in \mathbb{N}$ implies $\neg m <_{\mathbb{N}} 0$ with (4.188). Thus, $n = 0$ is false, and therefore the second part $n \in \mathbb{N}_+$ of the preceding disjunction is true. Now, $m \in \mathbb{N}$ implies $m = 0 \vee m \in \mathbb{N}_+$ again with (2.310), which disjunction we now use to prove the existential sentence in (5.325) by cases.

In case of $m = 0$, we obtain

$$m +_{\mathbb{N}} n = 0 +_{\mathbb{N}} n = n$$

by applying substitution and the fact that 0 is the neutral element for the addition on $\mathbb{N}$ (see Proposition 5.47). These equations give $m +_{\mathbb{N}} n = n$, where $n \in \mathbb{N}$ and $n \neq 0$ are also true, as shown before. This proves the existential sentence in (5.325) for the case $m = 0$.

In case of $m \in \mathbb{N}_+$, we have that m and n are both positive natural numbers, so that the corresponding initial segments $\{1, \ldots, m\}$ and $\{1, \ldots, n\}$ of $\mathbb{N}_+$ are defined to be nonempty sets. Furthermore, the assumed inequality $m <_{\mathbb{N}} n$ implies $\{1, \ldots, m\} \subset \{1, \ldots, n\}$ with Theorem 4.20 in connection with the definition of an initial segment of $\mathbb{N}_+$. Then, it follows with (2.127) and with (2.129) that the set difference

$$D = \{1, \ldots, n\} \setminus \{1, \ldots, m\}. \quad (5.326)$$

is a nonempty and proper subset of $\{1, \ldots, n\}$. We also notice that the initial segment $\{1, \ldots, n\}$ is a finite set with cardinality $|\{1, \ldots, n\}| = n$ according to Corollary 4.104. We may now apply Proposition 4.115 to infer from $n \in \mathbb{N}$, from the finiteness of $\{1, \ldots, n\}$, from the equation $|\{1, \ldots, n\}| = n$ and from the proper inclusion $D \subset \{1, \ldots, n\}$ that D is a finite set with cardinality $|D| <_{\mathbb{N}} n$. Since we showed that $D \neq \emptyset$ holds, we may further infer from this with (4.527) that $|D| \neq 0$ is true. Now, the initial segment $\{1, \ldots, m\}$ is also a finite set and has the cardinality $|\{1, \ldots, m\}| = m$ in view of Corollary 4.104. Moreover, (5.326) shows in light of (2.111) that $\{1, \ldots, m\} \cap D = \emptyset$ holds. Introducing the notation $\bar{d} = |D|$, we then see that the sum of the natural numbers m and $\bar{d}$ is determined by

$$\begin{aligned} m +_{\mathbb{N}} \bar{d} &= |\{1, \ldots, m\} \cup D| \\ &= |\{1, \ldots, m\} \cup (\{1, \ldots, n\} \setminus \{1, \ldots, m\})| \\ &= |(\{1, \ldots, n\} \setminus \{1, \ldots, m\}) \cup \{1, \ldots, m\}| \\ &= |\{1, \ldots, n\}| \\ &= n, \end{aligned}$$

using 5.185, (5.326), (2.214), (2.263) in connection with the fact that the previously established proper inclusion $\{1, \ldots, m\} \subset \{1, \ldots, n\}$ implies the inclusion $\{1, \ldots, m\} \subseteq \{1, \ldots, n\}$ due to (2.26), and finally the previously obtained equation $|\{1, \ldots, n\}| = n$. These equations then yield $m +_{\mathbb{N}} \bar{d} = n$, where $(|D| =)\ \bar{d} \neq 0$ holds, as shown earlier. Together with the evident fact that $\bar{d} \in \mathbb{N}$, we thus proved the existential sentence in (5.325) also for the case $m \in \mathbb{N}_+$, so that the proof of the first part of the equivalence in (5.325) is complete.

To prove the second part ('$\Leftarrow$'), we now assume that there exists a nonzero natural number, say $\bar{d}$, satisfying the equation $m +_{\mathbb{N}} \bar{d} = n$. Then, the Cartesian products

$$\begin{aligned} M &= \{1, \ldots, m\} \times \{0\}, \\ D &= \{1, \ldots, \bar{d}\} \times \{1\} \end{aligned}$$

have the cardinalities $|M| = m$ and $|D| = \bar{d}$ according to (4.508). Then, the sum of m and $\bar{d}$ may be expressed by

$$|M \cup D| = m +_{\mathbb{N}} \bar{d} = n,$$

according to (5.184. Let us here observe that $M \cup D$ is a finite set and that $M \cap D = \emptyset$ implies also $D \cap M = \emptyset$ with the Commutative Law for the intersection. The conjunction of the aforementioned inequality $D \neq \emptyset$

and the preceding equation then gives $M \subset M \cup D$ with (2.256). Thus, the previous findings show that the multiple conjunction

$$n \in \mathbb{N} \;\wedge\; M \cup D \text{ is finite } \wedge\; |M \cup D| = n \;\wedge\; M \subset M \cup D$$

is true, so that M is a finite set with cardinality $(m =)\ |M| <_{\mathbb{N}} n$, i.e. with $m <_{\mathbb{N}} n$, as desired. This completes the proof of the second part of the equivalence in (5.325), and the resultant truth of this equivalence proves then also the implication in (5.325). Moreover, as m and n were arbitrary, we may then further conclude that the universal sentence (5.325) holds. Thus, $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$ satisfies also Property 7 of an ordered elementary domain. □

Notation 5.12. We call

$$(\mathbb{N}, +, \cdot, <) = (\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}}) \tag{5.327}$$

the *ordered elementary domain of natural numbers*.

5.5.1. Basic laws for $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$

In the following, we restate for future reference the main Propositions, Corollaries and Theorems of Section 5.4 now for the specific ordered elementary domain $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$.

Corollary 5.81. *It is true for the ordered elementary domain of natural numbers that*

a) *every nonzero natural number is greater than* 0*, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow [n \neq 0 \Leftrightarrow 0 < n]). \tag{5.328}$$

b) *every natural number is greater than or equal to the zero element, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow [0 < n \,\vee\, n = 0). \tag{5.329}$$

Note 5.26. We may establish these properties also directly from the properties of the standard linear ordering $<_{\mathbb{N}}$ of $\mathbb{N}$, viz. by applying Corollary 4.37. Similarly, applying Corollary 5.60 to the ordered elementary domain of natural numbers yields the previously obtained sentence (4.188).

Corollary 5.82. *The sum of a nonzero natural number and any natural number is nonzero, i.e.*

$$\forall m, n\,([m, n \in \mathbb{N} \wedge m \neq 0] \Rightarrow m + n \neq 0). \tag{5.330}$$

Corollary 5.83 (Monotony Laws for natural numbers). *The following laws hold for the ordered elementary domain* $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$.

a) **Monotony Law for $+_{\mathbb{N}}$ and $<_{\mathbb{N}}$**:

$$\forall k, m, n\,(k, m, n \in \mathbb{N} \Rightarrow [k < m \Leftrightarrow k + n < m + n]). \tag{5.331}$$

b) **Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$**:

$$\forall k, m, n\,(k, m, n \in \mathbb{N} \Rightarrow [k \leq m \Leftrightarrow k + n \leq m + n]). \tag{5.332}$$

c) **Monotony Law for $\cdot_{\mathbb{N}}$ and $<_{\mathbb{N}}$**:

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge 0 < n] \Rightarrow [k < m \Leftrightarrow k \cdot n < m \cdot n]). \tag{5.333}$$

d) **Monotony Law for $\cdot_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$**:

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge 0 < n] \Rightarrow [k \leq m \Leftrightarrow k \cdot n \leq m \cdot n]). \tag{5.334}$$

Corollary 5.84 (Additivity of inequalities for natural numbers). *The following laws hold for the ordered elementary domain* $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$.

a) **Additivity of $<_{\mathbb{N}}$-inequalities**:

$$\forall j, k, m, n\,(j, k, m, n \in \mathbb{N} \Rightarrow [(j < k \wedge m < n) \Rightarrow j + m < k + n]). \tag{5.335}$$

b) **Additivity of $\leq_{\mathbb{N}}$-inequalities**:

$$\forall j, k, m, n\,(j, k, m, n \in \mathbb{N} \Rightarrow [(j \leq k \wedge m \leq n) \Rightarrow j + m \leq k + n]). \tag{5.336}$$

Corollary 5.85 (Cancellation Laws for natural numbers). *The following laws are true for the ordered elementary domain* $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$.

a) **Cancellation Law for $+_{\mathbb{N}}$**:

$$\forall k, m, n\,(k, m, n \in \mathbb{N} \Rightarrow [k + m = k + n \Rightarrow m = n]). \tag{5.337}$$

b) **Cancellation Law for $\cdot_{\mathbb{N}}$**:

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge k \neq 0] \Rightarrow [k \cdot m = k \cdot n \Rightarrow m = n]). \tag{5.338}$$

c) **Cancellation Law for 0**:

$$\forall n\,(n \in \mathbb{N} \Rightarrow [n \cdot 0 = 0 \wedge 0 \cdot n = 0]). \tag{5.339}$$

Corollary 5.86. *It is true that, if a natural number n is the sum of two natural numbers m and d, then n is greater than or equal to m, i.e.*

$$\forall m, n, d\,([m, n, d \in \mathbb{N} \,\wedge\, m + d = n] \Rightarrow m \leq n). \tag{5.340}$$

Note 5.27. The Distinctness of the zero element and the unity element in the ordered elementary domain of natural numbers was already established in (4.165). Furthermore, the fact that the zero element 0 is less than the unity element 1 was indicated by (4.164).

Corollary 5.87. *The following sentence is true for the ordered elementary domain of natural numbers.*

$$\forall k, m, n\,(k, m, n \in \mathbb{N} \Rightarrow [k \leq m \Rightarrow k \cdot n \leq m \cdot n]). \tag{5.341}$$

5.5.2. Differences of natural numbers

Corollary 5.88. *For any natural numbers m and n such that m is less than or equal to n, it is true that there exists a unique natural number d such that n is the sum of m and d, that is,*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m \leq n \Rightarrow \exists! d\,(d \in \mathbb{N} \,\wedge\, m + d = n)]). \tag{5.342}$$

Thus, the difference of two natural numbers n and m satisfying $m \leq n$ is defined as the unique natural number $d = n - m$ which satisfies $m + d = n$.

Note 5.28. Whenever we encounter an equation $m + d = n$, the difference $d = n - m$ exists since the given equation implies the required inequality $m \leq n$ with Corollary 5.86.

Corollary 5.89. *The following sentences holds for the ordered elementary domain of natural numbers.*

$$\forall m, n\,([m, n \in \mathbb{N} \,\wedge\, m \leq n] \Rightarrow [n - m] + m = n). \tag{5.343}$$

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [n + m] - m = n). \tag{5.344}$$

Corollary 5.90. *The difference of any natural number n and itself is zero, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow n - n = 0). \tag{5.345}$$

Furthermore, any natural number is identical with the difference of itself and 0, that is,

$$\forall n\,(n \in \mathbb{N} \Rightarrow n = n - 0). \tag{5.346}$$

Corollary 5.91. *The following laws hold for the ordered elementary domain of natural numbers.*

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge n \leq k \wedge m \leq n] \Rightarrow [k-m]+[m-n]=k-n), \tag{5.347}$$

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge n \leq k \wedge m \leq n] \Rightarrow [k-n]-[k-m]=m-n) \tag{5.348}$$

Corollary 5.92 (Distributive law for the difference of natural numbers). *The following sentence is true for the ordered elementary domain of natural numbers.*

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge n \leq m] \Rightarrow k \cdot [m-n]=k \cdot m-k \cdot n). \tag{5.349}$$

Corollary 5.93 (Monotony Laws for the difference of natural numbers). *The following laws hold for the ordered elementary domain of natural numbers.*

a) **Monotony Law for $-_{\mathbb{N}}$ and $<_{\mathbb{N}}$***:*

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge n \leq k] \Rightarrow [k<m \Rightarrow k-n<m-n]). \tag{5.350}$$

b) **Monotony Law for $-_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$***:*

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge n \leq k] \Rightarrow [k \leq m \Rightarrow k-n \leq m-n]). \tag{5.351}$$

Corollary 5.94. *For any natural numbers m and n, it is true that, if m is less than n, then the difference of n and m is greater than zero, i.e.*

$$\forall m, n\,(m, n \in \mathbb{N} \Rightarrow [m<n \Rightarrow n-m>0]). \tag{5.352}$$

Corollary 5.95. *The following laws are true for the ordered elementary domain of natural numbers.*

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge k \leq m] \Rightarrow [n \leq k \Rightarrow m-k \leq m-n]), \tag{5.353}$$

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge k \leq m] \Rightarrow [n<k \Rightarrow m-k<m-n]). \tag{5.354}$$

Corollary 5.96. *Subtracting two natural numbers m and n successively from a natural number k gives the same result as subtracting the sum of m and n from k, given that this sum is less than or equal to k, i.e.*

$$\forall k, m, n\,([k, m, n \in \mathbb{N} \wedge m+n \leq k] \Rightarrow (k-m)-n=k-(m+n)). \tag{5.355}$$

5.5.3. Tails of a sequence

Proposition 5.97. *The following sequences are true for any set Y, any sequence $f = (a_n)_{n\in\mathbb{N}_+}$ in Y and any $N \in \mathbb{N}_+$.*

a) There exists the unique sequence $t_N = (m_n)_{n\in\mathbb{N}_+}$ such that

$$t_N : \mathbb{N}_+ \to \mathbb{N}_+, \quad n \mapsto m_n = (N + n) - 1. \tag{5.356}$$

b) Then, the composition $T_N^f = f \circ t_N$ is a subsequence of $(a_n)_{n\in\mathbb{N}_+}$.

Proof. We let Y, f and N be an arbitrary sets such that $f = (a_n)_{n\in\mathbb{N}_+}$ is a sequence in Y and such that $N \in \mathbb{N}_+$ holds.

Concerning a), we may apply Function definition by replacement to establish the sequence t_N with domain $\mathbb{N}_+$ such that

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow t_N(n) = [N + n] - 1) \tag{5.357}$$

holds. For this purpose, we verify

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \exists! m\,(m = [N + n] - 1)). \tag{5.358}$$

We let $n \in \mathbb{N}_+$ be arbitrary, so that $n \in \mathbb{N}$ follows to be true by definition of the set of positive natural numbers (and the definition of a subset). Let us now observe that the assumed $N \in \mathbb{N}_+$ implies for the same reason that $N \in \mathbb{N}$ and $N \notin \{0\}$ holds, where the latter gives $N \neq 0$ with (2.169). Because of these findings, we may use (5.330) to obtain $N + n \neq 0$, which evidently gives $N + n \in \mathbb{N}$ and $N + n \notin \{0\}$, so that $N + n \in \mathbb{N}_+$. Consequently, the inequality $1 \leq N + n$ holds according to (4.278), which shows that the difference $[N + n] - 1$ exists uniquely (in $\mathbb{N}$). Then, the uniquely existential sentence in (5.358) follows to be true with (1.109). As n is arbitrary, we may therefore conclude that the universal sentence (5.358) holds, so that there exists a unique function t_N with domain $\mathbb{N}_+$ satisfying (5.357). Thus, we may view t_N as the sequence $(m_n)_{n\in\mathbb{N}_+}$ with $m_n = t_N(n) = (N + n) - 1$ for any $n \in \mathbb{N}_+$.

To prove that $\mathbb{N}_+$ is a codomain of t_N, we verify $\mathrm{ran}(t_N) \subseteq \mathbb{N}_+$. To do this, we apply the definition of a subset and prove the equivalent

$$\forall m\,(m \in \mathrm{ran}(t_N) \Rightarrow m \in \mathbb{N}_+). \tag{5.359}$$

Letting m be an arbitrary element of $\mathrm{ran}(t_N)$, there exists by definition of a range an element, say $\bar{n}$, with $(\bar{n}, m) \in t_N$. As t_N is a function, we may write this also as $m = t_N(\bar{n})$. By definition of t_N, we obtain $[m =]\ t_N(\bar{n}) = m_{\bar{n}} = (N+\bar{n})-1$, which gives $m = (N+\bar{n})-1$. Furthermore, since the domain of t_N is $\mathbb{N}_+$, it follows from $(\bar{n}, m) \in t_N$ that $\bar{n} \in \mathbb{N}_+$ holds. The latter finding and $N \in \mathbb{N}_+$ evidently imply $1 \leq \bar{n}$ as well as $1 \leq N$. Applying now the Monotony Law for $+_\mathbb{N}$ and $\leq_\mathbb{N}$, we obtain the inequalities

$$\begin{aligned} 1 + 1 &\leq \bar{n} + 1, \\ 1 + \bar{n} &\leq N + \bar{n}, \end{aligned}$$

which further imply $1 + 1 \leq N + \bar{n}$ with the commutativity of $+_\mathbb{N}$ and the transitivity of $\leq_\mathbb{N}$. Since $1 < 2$ holds according to (4.166), the disjunction $1 < 2 \vee 1 = 2$ is also true, so that we obtain $1 \leq 2$ by definition of an induced reflexive partial ordering; here we have $2 = 1^+ = 1+1$ due to (2.292) and (5.217), so that we may write the preceding inequality also as $1 \leq 1+1$. We may therefore apply the Monotony Law for $-_\mathbb{N}$ and $\leq_\mathbb{N}$ to infer from $1 + 1 \leq N + \bar{n}$ the truth of the inequality $(1 + 1) - 1 \leq (N + \bar{n}) - 1$ $[= m]$, which yields $1 \leq m$ with (5.344). Since $0 < 1$ also holds in view of (4.164), we obtain with the Transitivity Formula for $<$ and $\leq$ the inequality $0 < m$, and then $m \neq 0$ with the Characterization of comparability (applied to the standard linear ordering of $\mathbb{N}$). Thus, $m \in \mathbb{N}$ and $m \notin \{0\}$ are evidently true, so that the desired consequent $m \in \mathbb{N}_+$ follows to be true. As m was arbitrary, we may therefore conclude that the universal sentence (5.359) holds, which gives the $\mathrm{ran}(t_N) \subseteq \mathbb{N}_+$ with the definition of a subset. This finding shows that $\mathbb{N}_+$ is indeed a codomain of t_N, which is thus characterized by (5.356).

Concerning b), we first verify that the sequence $t_N = (m_n)_{n \in \mathbb{N}_+}$ is strictly increasing, by applying the Monotony Criterion for strictly increasing sequences. For this purpose, we let $n \in \mathbb{N}_+$ be arbitrary and show that this implies $m_n < m_{n+1}$. Let us observe the truth of $N + n < (N + n) + 1$ in light of (4.153) and (5.217). This inequality then implies

$$(N + n) - 1 < ([N + n] + 1) - 1$$

with the Monotony Law for $-_\mathbb{R}$ and $<_\mathbb{R}$, which we may apply because the assumed $n, N \in \mathbb{N}_+$ implies $1 \leq 2 \leq N + n$ (as mentioned in the proof of a)) and therefore $1 \leq N + n$ (applying the transitivity of the total ordering $\leq_\mathbb{N}$). By definition of t_N, we have the terms $m_n = (N + n) - 1$ and

$$m_{n+1} = (N + [n + 1]) - 1 = ([N + n] + 1) - 1$$

(where we applied the commutativity of $+_\mathbb{N}$), so that substitution yields the desired inequality $m_n < m_{n+1}$. As n was arbitrary, we may therefore conclude that $t_N = (m_n)_{n \in \mathbb{N}_+}$ satisfies the Monotony Criterion for strictly increasing sequences. Based on this finding, Exercise 4.26a) shows that the composition $f \circ t_N$ yields the sequence $(a'_n)_{n \in \mathbb{N}_+} = (a_{m_n})_{n \in \mathbb{N}_+}$ in Y, which is then by definition a subsequence of $(a_n)_{n \in \mathbb{N}_+}$. $\square$

Definition 5.20 (Tail). For any set Y, any sequence $f = (a_n)_{n\in\mathbb{N}_+}$ in Y and any $N \in \mathbb{N}_+$, we call

$$T_N^f = f \circ t_N = (a'_n)_{n\in\mathbb{N}_+} = (a_{m_n})_{n\in\mathbb{N}_+} = (a_{[N+n]-1})_{n\in\mathbb{N}_+} \tag{5.360}$$

the *N-th tail* of $(a_n)_{n\in\mathbb{N}_+}$.

Exercise 5.40. Show

a) for any set Y and any addition $+_Y$ on Y such that Y contains the zero element 0_Y, as well as for any elements $\bar{a}, \bar{b} \in Y$, that there exists a unique sequence $f = (a_n)_{n\in\mathbb{N}_+}$ in Y such that

$$a_n = \begin{cases} \bar{a} & \text{if } n = 1 \\ \bar{b} & \text{if } n = 2 \\ 0_Y & \text{if } n > 2 \end{cases} \tag{5.361}$$

b) for any set system $\mathcal{K}$ with $\emptyset \in \mathcal{K}$ as well as any sets $\bar{A}, \bar{B} \in \mathcal{K}$ that there is a unique sequence of sets $(A_n)_{n\in\mathbb{N}_+}$ in $\mathcal{K}$ such that

$$A_n = \begin{cases} \bar{A} & \text{if } n = 1 \\ \bar{B} & \text{if } n = 2 \\ \emptyset & \text{if } n > 2 \end{cases}, \tag{5.362}$$

and that the union of this sequence equals the union of $\bar{A}$ and $\bar{B}$, i.e.

$$\bigcup_{n=1}^{\infty} A_n = \bar{A} \cup \bar{B}. \tag{5.363}$$

(Hint: Define the sequences by replacement and apply then the definition of a codomain; concerning b), use the Characterization of the union of a family of sets.)

Proposition 5.98. *For any set Y and any addition $+_Y$ on Y such that Y contains the zero element 0_Y, as well as for any elements $\bar{a}, \bar{b} \in Y$, it is true that the third tail of the sequence $f = (a_n)_{n\in\mathbb{N}_+}$ defined by (5.361) is identical with the constant function on $\mathbb{N}_+$ with value 0_Y, i.e.*

$$T_3^f = \mathbb{N}_+ \times \{0_Y\} \quad [= g_{0_Y}]. \tag{5.364}$$

Proof. We let Y and $+_Y$ be arbitrary sets, assume that $+$ is a addition on Y and that Y contains the neutral element 0_Y with respect to that addition, and we let $\bar{a}, \bar{b}$ be arbitrary elements of Y. Let us first observe that the tail T_3^f of the function f defined in Exercise 5.40 and the constant function $g_{0_Y} = \mathbb{N}_+ \times \{0_Y\}$ are both functions with domain $\mathbb{N}_+$, so that we may apply the Equality Criterion for functions to establish their identity. Letting $n \in \mathbb{N}_+$ be arbitrary, we notice the truth of $0 < 1 \leq n$ in view of (4.164) as well as (4.278), which inequalities give $0 < n$ with the Transitivity Formula for $<$ and $\leq$, and furthermore $0 + 2 < n + 2$ with the Monotony Law for $+_{\mathbb{N}}$ and $<_{\mathbb{N}}$. We therefore obtain $n + 2 > 2$ with the definition of a neutral element, which in turn yields $a_{n+2} = 0_Y$ with (5.361). Let us also observe the truth of the equations

$$\begin{aligned}[3+n]-1 &= [n+3]-1 \\ &= [n+2^+]-1 \\ &= [n+(2+1)]-1 \\ &= [(n+2)+1]-1 \\ &= n+2\end{aligned}$$

in view of the commutativity of $+_{\mathbb{N}}$, (2.293), (5.217), the associativity of $+_{\mathbb{N}}$, and (5.344). These findings, alongside the definition of a tail and Corollary 3.154 then yield the true equations

$$T_3^f(n) = a_{[3+n]-1} = a_{n+2} = 0_Y = g_{0_Y}(n).$$

As n is arbitrary, we may therefore infer from the resulting equation $T_3^f(n) = g_{0_Y}(n)$ the truth of the proposed identity $T_3^f = g_{0_Y}$.

Since Y, $+_Y$, $\bar{a}$ and $\bar{b}$ were initially arbitrary, we may further conclude that the proposition is true. $\square$

Exercise 5.41. Show for any set system $\mathcal{K}$ with $\emptyset \in \mathcal{K}$ and for any sets $\bar{A}, \bar{B} \in \mathcal{K}$ that the third tail of the sequence of sets $f = (A_n)_{n \in \mathbb{N}_+}$ defined by (5.362) equals both the constant function on $\mathbb{N}_+$ with value $\emptyset$ and the Cartesian product of the set of positive natural numbers and the natural number 1, i.e.

$$T_3^f = g_\emptyset = \mathbb{N}_+ \times 1. \tag{5.365}$$

(Hint: Recall (2.155).)

The range of a tail may be characterized as the range of a restriction of the original sequence to a subset of $\mathbb{N}_+$ without an initial segment.

Theorem 5.99 (Characterization of the range of a tail). *For any set Y, any sequence $f = (a_n)_{n \in \mathbb{N}_+}$ in Y and any $N \in \mathbb{N}_+$, it is true that the range of the N-th tail of f is identical with the range of the restriction of f to $\mathbb{N}_+ \setminus \{1, \ldots, N-1\}$, i.e.*

$$\mathrm{ran}(T_N^f) = \mathrm{ran}(f \upharpoonright \mathbb{N}_+ \setminus \{1, \ldots, N-1\}). \tag{5.366}$$

Proof. We let Y, f and N be arbitrary sets, we assume that $f = (a_n)_{n\in\mathbb{N}_+}$ is a sequence in Y, and we assume $N \in \mathbb{N}_+$ to be true, so that $T^f_N = (a'_n)_{n\in\mathbb{N}_+}$ is the N-th tail of f, whose terms thus satisfy $a'_n = a_{[N+n]-1}$ for any $n \in \mathbb{N}_+$. We also see that $N \in \mathbb{N}_+$ implies $1 \leq N$ with (4.278) and evidently $N \in \mathbb{N}$ with the definition of the set of positive natural numbers, so that the difference $N - 1$ exists indeed (in $\mathbb{N}$). Now, to establish the proposed equation, we verify

$$\forall y\,(y \in \mathrm{ran}(f \restriction \mathbb{N}_+ \setminus \{1, \ldots, N-1\}) \Leftrightarrow y \in \mathrm{ran}(T^f_N)). \tag{5.367}$$

For this purpose, we let y be arbitrary and prove the first part ('$\Rightarrow$') of the equivalence directly, assuming that y is in the range of the restriction $f \restriction \mathbb{N}_+ \setminus \{1, \ldots, N-1\}$). Then, there exists (by definition of a range) a constant, say $\bar{n}$, with

$$(\bar{n}, y) \in f \restriction \mathbb{N}_+ \setminus \{1, \ldots, N-1\},$$

which implies $\bar{n} \in \mathbb{N}_+ \setminus \{1, \ldots, N-1\}$ and $(\bar{n}, y) \in f$ by definition of a restriction. Here, we may write the latter also as $y = f(\bar{n}) = a_{\bar{n}}$ (since f is a function/sequence), whereas the former means by definition of a set difference that $\bar{n} \in \mathbb{N}_+$ and $\bar{n} \notin \{1, \ldots, N-1\}$ hold. Here, $\bar{n} \in \mathbb{N}_+$ gives the inequality $1 \leq \bar{n}$ with (4.278). Let us now observe that the previously established $1 \leq N$ implies $1 < N \vee 1 = N$ with the definition of an induced reflexive partial ordering; we use this disjunction to prove the sentence $N \leq \bar{n}$ by cases.

In the first case of $1 < N$, we notice that $1 \leq 1$ holds because the standard total ordering of $\mathbb{N}$ is reflexive. Then, the previous two inequalities imply $1 - 1 < N - 1$ with the Monotony Law of $-_{\mathbb{N}}$ and $<_{\mathbb{N}}$, so that we obtain $0 < N - 1$ with (5.345). An application of (5.328) therefore gives $N - 1 \neq 0$, which in turn implies $N - 1 \notin \{0\}$ with (2.169). Together with $N - 1 \in \mathbb{N}$, this further implies $N - 1 \in \mathbb{N}_+$, so that we may use (4.275) and the Law of Contraposition to infer from the previously found negation $\neg \bar{n} \in \{1, \ldots, N-1\}$ the truth of the negation $\neg \bar{n} \leq N - 1$, which yields $N - 1 < \bar{n}$ with the Negation Formula for $\leq$. Consequently, we obtain $(N-1)+1 \leq \bar{n}$ with (5.217) and (4.270), and we may write this inequality as $N \leq \bar{n}$ according to (5.343).

In the second case of $1 = N$, we may apply substitution to the previously established inequality $1 \leq \bar{n}$ to obtain the desired $N \leq \bar{n}$, so that the proof by cases is complete.

Thus, the difference $\bar{n} - N$ exists in $\mathbb{N}$, and its successor, which we write as $(\bar{n} - N) + 1$ due to (5.217), is then an element of $\mathbb{N}_+$ in view of (4.40).

We then obtain the true equations

$$\begin{aligned} T_N^f([\bar{n} - N] + 1) &= a'_{[\bar{n}-N]+1} = a_{[N+([\bar{n}-N]+1)]-1} \\ &= a_{[(N+[\bar{n}-N])+1]-1} \\ &= a_{N+[\bar{n}-N]} \\ &= a_{[\bar{n}-N]+N} \\ &= a_{\bar{n}} \\ &= y, \end{aligned}$$

by using the definition of a tail, the associativity of $+_{\mathbb{N}}$, (5.344), the commutativity of $+_{\mathbb{N}}$, (5.343), and finally the previously obtained equation $y = a_{\bar{n}}$. As the tail is a sequence/function, we may write the resulting equation $y = T_N^f([\bar{n} - N] + 1)$ also as $([\bar{n} - N] + 1, y) \in T_N^f$, which implies the desired $y \in \mathrm{ran}(T_N^f)$ by definition of a range.

To prove the second part ('$\Leftarrow$') of the equivalence, we now assume that $y \in \mathrm{ran}(T_N^f)$ holds, and we may use some of the arguments of the first part to establish the desired consequent. To begin with, the preceding assumption implies that there exists a constant, say $\bar{m}$, such that $(\bar{m}, y) \in T_N^f$ holds. On the one hand, this gives

$$y = T_N^f(\bar{m}) = a'_{\bar{m}} = a_{[N+\bar{m}]-1} = f([N + \bar{m}] - 1), \tag{5.368}$$

and on the other hand $\bar{m} \in \mathbb{N}_+$ $(= \mathrm{dom}(T_N^f))$ with the definition of a domain. Then, $\bar{m} \in \mathbb{N}_+$ and $N \in \mathbb{N}_+$ evidently imply $1 \leq \bar{m}$ and $1 \leq N$, which inequalities we may add to obtain $1+1 \leq N+\bar{m}$. Because of $1 \leq 1+1$, we may now form the inequality $(1 + 1) - 1 \leq (N + \bar{m}) - 1$, which we may write also as $[0 <]\ 1 \leq (N + \bar{m}) - 1$. Therefore, $0 < (N + \bar{m}) - 1$ is true, so that $(N + \bar{m}) - 1 \neq 0$ holds, with the consequence that

$$(N + \bar{m}) - 1 \in \mathbb{N}_+. \tag{5.369}$$

Furthermore, $[0 <]\ 1 \leq \bar{m}$ gives $0 < \bar{m}$ and then $0 + N < \bar{m} + N$, which results in $N < N + \bar{m}$. Because of $1 \leq N$, we may therefore form the inequality $N - 1 < (N + \bar{m}) - 1$, which yields the negation

$$\neg (N + \bar{m}) - 1 \leq N - 1. \tag{5.370}$$

Let us consider now again the two cases $1 < N$ and $1 = N$ in order to prove the sentence

$$(N + \bar{m}) - 1 \in \mathbb{N}_+ \setminus \{1, \ldots, N - 1\}. \tag{5.371}$$

We already showed that the first case gives $N - 1 \in \mathbb{N}_+$; since (5.369) also holds, we may infer from (5.370) the truth of the negation $\neg (N + \bar{m}) - 1 \in$

$\{1, \ldots, N-1\}$ because of (4.275). The conjunction of (5.369) and the preceding finding yields then the desired sentence (5.371).

The second case $N = 1$ gives

$$\begin{aligned}\mathbb{N}_+ \setminus \{1, \ldots, N-1\} = \mathbb{N}_+ \setminus \{1, \ldots, 1-1\} = \mathbb{N}_+ \setminus \{1, \ldots, 0\} = \mathbb{N}_+ \setminus \emptyset \\ = \mathbb{N}_+.\end{aligned}$$

by applying substitution, (5.345), the notation for initial segments of $\mathbb{N}_+$, and (2.102). Therefore, (5.369) implies via substitution (5.371), completing the proof by cases.

The equations in (5.368) give $y = f([N+\bar{m}]-1)$, which we may write as $([N+\bar{m}]-1, y) \in f$. Together with (5.371), this implies with the definition of a restriction

$$([N+\bar{m}]-1, y) \in f \upharpoonright \mathbb{N}_+ \setminus \{1, \ldots, N-1\},$$

so that y follows to be an element of the range of that restriction. Thus, the proof of the second part of the equivalence (5.367) is complete. Since y is arbitrary, we may therefore conclude that the universal sentence (5.367) is true, which then implies the proposed equation (5.366) with the Equality Criterion for sets. As Y, f and N were initially arbitrary sets, we may finally infer from this the truth of the stated theorem. □

Proposition 5.100. *For any set Y, any sequence $f = (a_n)_{n \in \mathbb{N}_+}$ in Y and any $M, N \in \mathbb{N}_+$ with $M \leq_{\mathbb{N}} N$, it is true that the N-th tail of f is the $(N-M+1)$-th tail of the M-th tail of f, i.e.*

$$\forall Y, f, M, N\, ([f \in Y^{\mathbb{N}_+} \wedge M, N \in \mathbb{N}_+ \wedge M \leq_{\mathbb{N}} N] \Rightarrow T_N^f = T_{[N-M]+1}^{T_M^f}). \tag{5.372}$$

Proof. We let Y, f, M and N be arbitrary sets such that $f = (a_n)_{n \in \mathbb{N}_+}$ is a sequence in Y and such that $M, N \in \mathbb{N}_+$ and $M \leq_{\mathbb{N}} N$ are true. By definition of a tail, we may write

$$T_M^f = (a'_n)_{n \in \mathbb{N}_+} = (a_{[M+n]-1})_{n \in \mathbb{N}_+}, \tag{5.373}$$

$$T_N^f = (a''_n)_{n \in \mathbb{N}_+} = (a_{[N+n]-1})_{n \in \mathbb{N}_+}, \tag{5.374}$$

$$\tag{5.375}$$

Next, we notice that $M \leq_{\mathbb{N}} N$ implies $N - M \in \mathbb{N}$ with the definition of a difference and then $(N-M)+1 \in \mathbb{N}_+$ with the fact that the range of the successor function on $\mathbb{N}$ equals $\mathbb{N}_+$. With this finding, we see that the

$([N-M]+1)$-th tail of T_M^f exists, which we may then write as

$$\begin{aligned} T_{[N-M]+1}^{T_M^f} &= (a'_{[([N-M]+1)+n]-1})_{n\in\mathbb{N}_+} \\ &= (a'_{[([N-M]+n)+1]-1})_{n\in\mathbb{N}_+} \\ &= (a'_{[N-M]+n})_{n\in\mathbb{N}_+} \\ &= (a_{[M+([N-M]+n)]-1})_{n\in\mathbb{N}_+} \\ &= (a_{[([N-M]+M)+n]-1})_{n\in\mathbb{N}_+} \\ &= (a_{[N+n]-1})_{n\in\mathbb{N}_+} \\ &= T_N^f \end{aligned}$$

using the definition of a tail (of T_M^f), the associativity as well as the commutativity of $\mathbb{N}_+$, (5.344), then (5.373), the associativity as well as the commutativity of $\mathbb{N}_+$, subsequently (5.343), and finally (5.374); thus the equation in (5.372) is true. Since Y, f, M and N were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Since tails are subsequences according to Proposition 5.97b), the following tail characteristics follow immediately from Proposition 4.80, Exercise 4.27 and Corollary 4.81.

Corollary 5.101. *For any partially ordered set $(Y, \leq_Y)$ it is true that*

a) any tail of any bounded-from-below sequence in Y is itself bounded from below (by the same lower bound).

b) any tail of any bounded-from-above sequence in Y is itself bounded from above (by the same upper bound).

c) any tail of any bounded sequence in Y is itself bounded.

Furthermore, we see that Proposition 4.82, Exercise 4.28 and Corollary 4.83 apply in particular to tails.

Corollary 5.102. *For any partially ordered set $(Y, \leq_Y)$ it is true that*

a) any tail of any increasing sequence in Y is itself increasing.

b) any tail of any decreasing sequence in Y is itself decreasing.

c) any tail of any monotone sequence in Y is itself monotone.

Proposition 5.103. *For any partially ordered set $(Y, \leq_Y)$, any decreasing sequence $f = (a_n)_{n\in\mathbb{N}_+}$ in Y, any $N \in \mathbb{N}_+$ and any $a \in X$, it is true that a is a lower bound for f iff a is a lower bound for the N-th tail of f.*

Proof. We let Y, $\leq_Y$, f, N and a be arbitrary and assume then $(Y, \leq_Y)$ to be a partially ordered set, $f = (a_n)_{n \in \mathbb{N}_+}$ to be a decreasing sequence in Y, N to be a positive natural number and a to be an element of Y. To prove the first part ('$\Rightarrow$') of the proposed equivalence, we assume that a is a lower bound for f, which already implies with Corollary 5.101a) that a is a lower bound for the tail T_N^f of f. To prove the second part ('$\Leftarrow$'), we now assume that a is a lower bound for T_N^f, i.e. that

$$\forall y\,(y \in \operatorname{ran}(T_N^f) \Rightarrow a \leq_Y y) \tag{5.376}$$

holds. To prove that a is also a lower bound for f, we verify accordingly

$$\forall y\,(y \in \operatorname{ran}(f) \Rightarrow a \leq_Y y). \tag{5.377}$$

To do this, we let $\bar{y}$ be arbitrary and assume $\bar{y} \in \operatorname{ran}(f)$, so that there exists by definition of a range a constant, say $\bar{n}$, such that $(\bar{n}, \bar{y}) \in f$ holds. This implies on the one hand $\bar{y} = f(\bar{n}) = a_{\bar{n}}$, and on the other hand $\bar{n} \in \mathbb{N}_+$ $[= \operatorname{dom}(f)]$ by definition of a domain. Since the disjunction $N \leq_{\mathbb{N}} \bar{n} \vee \neg N \leq_{\mathbb{N}} \bar{n}$ is true according to the Law of the Excluded Middle, we may now prove the desired consequent $a \leq_Y \bar{y}$ by cases.

The first case $N \leq_{\mathbb{N}} \bar{n}$ implies $\bar{n} - N \in \mathbb{N}$ with the definition of a difference and then $[\bar{n} - N] + 1 \in \mathbb{N}_+$ by using (5.217) together with the fact that the successor function on $\mathbb{N}$ is a bijection with range $\mathbb{N}_+$. Therefore, the $([\bar{n} - N] + 1)$-th term of the tail T_N^f is defined, and we obtain the equations

$$\begin{aligned} T_N^f([\bar{n} - N] + 1) &= a'_{[\bar{n}-N]+1} = a_{[N+([\bar{n}-N]+1)]-1} \\ &= a_{[([\bar{n}-N]+N)+1]-1} \\ &= a_{[(\bar{n})+1]-1} \\ &= a_{\bar{n}} \\ &= \bar{y} \end{aligned}$$

applying the definition of a tail, the associativity and commutativity of $+_{\mathbb{N}}$, then (5.343), subsequently (5.344), and finally substitution. We may write the resulting equation $\bar{y} = T_N^f([\bar{n} - N] + 1)$ also as $([\bar{n} - N] + 1, \bar{y}) \in T_N^f$, which yields (by definition of a range) $\bar{y} \in \operatorname{ran}(T_N^f)$, so that the desired inequality $a \leq_Y \bar{y}$ follows to be true with (5.376).

In the other case of $\neg N \leq_{\mathbb{N}} \bar{n}$, which implies $\bar{n} <_{\mathbb{N}} N$ with the Negation Formula for $\leq$, it follows that $[\bar{y} =]\ a_{\bar{n}} \geq_Y a_N$ holds because the sequence $(a_n)_{n \in \mathbb{N}_+}$ was assumed to be decreasing. Due to $1 \in \mathbb{N}_+$, we evidently obtain

$$T_N^f(1) = a'_1 = a_{[N+1]-1} = a_N,$$

so that the preceding inequality becomes $a_1' \leq_Y \bar{y}$. Furthermore, we may write the first of the previous equations as $(1, a_1') \in T_N^f$, which gives (by definition of a range) $a_1' \in \text{ran}(T_N^f)$, and this finding implies now $a \leq_Y a_1'$ with (5.376). Having found the two inequalities $a \leq_Y a_1' \leq_Y \bar{y}$, we now see in light of the transitivity of the reflexive partial ordering $\leq_Y$ that $a \leq_Y \bar{y}$ is also true in the second case.

Thus, the proof by cases is complete, and as $\bar{y}$ is arbitrary, we may therefore conclude that (5.377) holds, so that a is indeed a lower bound for the sequence f. This completes the proof of the stated equivalence, and since Y, $\leq_Y$, f, N and a were initially arbitrary, we may now finally conclude that the proposition is true. □

Exercise 5.42. Show for any partially ordered set $(X, \leq_X)$, any increasing sequence $f = (a_n)_{n \in \mathbb{N}_+}$ in X, any $N \in \mathbb{N}_+$ and any $u \in X$ that u is an upper bound for f iff u is an upper bound for the N-th tail of f.

Theorem 5.104 (Tail Criterion for convergence of an increasing & of a decreasing sequence). *The following sentences are true for any partially ordered set $(Y, \leq_Y)$, any $N \in \mathbb{N}_+$, and any $L \in Y$.*

a) For any increasing sequence $s = (a_n)_{n \in \mathbb{N}_+}$ in Y it is true that s converges increasingly to L iff the N-th tail $T_N^s = (a_n')_{n \in \mathbb{N}_+}$ of s converges increasingly to L, i.e.

$$L = \lim_{n \to \infty} a_n = \sup \text{ran}(s) \;\Leftrightarrow\; L = \lim_{n \to \infty} a_n' = \sup \text{ran}(T_N^s). \quad (5.378)$$

b) For any decreasing sequence $s = (a_n)_{n \in \mathbb{N}_+}$ in Y it is true that s converges decreasingly to L iff the N-th tail $T_N^s = (a_n')_{n \in \mathbb{N}_+}$ of s converges decreasingly to L, i.e.

$$L = \lim_{n \to \infty} a_n = \inf \text{ran}(s) \;\Leftrightarrow\; L = \lim_{n \to \infty} a_n' = \inf \text{ran}(T_N^s). \quad (5.379)$$

Proof. We let Y, $\leq_Y$, f, N and L be arbitrary and assume $(Y, \leq_Y)$ to be a partially ordered set, $f = (a_n)_{n \in \mathbb{N}_+}$ to be an increasing sequence in Y, N to be a positive natural number, and L to be an element of Y.

To prove the first part ('⇒') of the equivalence, we assume that the sequence s converges increasingly to L, i.e.

$$L = \lim_{n \to \infty} a_n = \sup \text{ran}(s). \quad (5.380)$$

Since s is by assumption increasing and since the N-th tail $T_N^s = (a_n')_{n \in \mathbb{N}_+}$ of s is a subsequence of s according to Proposition 5.97, it follows that T_N^s

is also increasing in view Proposition 4.82. Furthermore, as the supremum $L = \sup \operatorname{ran}(s)$ is an upper bound for s, it follows that L is also an upper bound for the tail T_N^s due to Exercise 4.27. To prove that L is the supremum of the range of T_N^s, we let S' be an arbitrary upper bound for $\operatorname{ran}(T_N^s)$ and demonstrate that this implies $L \leq_Y S'$. Since s is increasing and since T_N^s is a tail of s, it then follows with Exercise 5.42 that S' is also an upper bound for (the range of) s. Since L was assumed to be the supremum of the range of s, we obtain $L \leq_Y S'$, as desired, completing the proof that L is the supremum of the range of $T_N^s = (a'_n)_{n \in \mathbb{N}_+}$. By definition of the limit of an increasing sequence, we thus have that

$$L = \sup \operatorname{ran}(T_N^s) = \lim_{n \to \infty} a'_n. \tag{5.381}$$

To prove the second part ('$\Leftarrow$') of the equivalence (5.378), we now assume that the tail T_N^s converges increasingly to L, i.e. we assume (5.381) to be true. Now, since s is increasing and since the supremum L of $\operatorname{ran}(T_N^s)$ is an upper bound for the N-the tail T_N^s of s, it follows with Exercise 5.42 that L is an upper bound also for s. Next, we demonstrate that L is the least upper bound for s, by letting S' be an arbitrary upper bound for s and by showing that this implies $L \leq_Y S'$. Clearly, S' is then also an upper bound for the tail T_N^s of s, which gives the desired $L \leq_Y S'$ because $L = \sup \operatorname{ran}(T_N^s)$ is the least upper bound for T_N^s. Thus, the proof that L is the least upper bound also for s is complete, so that $L = \sup \operatorname{ran}(s)$ holds. By definition of an increasingly convergent sequence, this yields (5.380), which completes the proof of the equivalence (5.378).

Since Y, $\leq_Y$, f, N and L were arbitrary, it follows then that Part a) of the theorem holds. $\square$

Exercise 5.43. Prove the Tail Criterion for convergence of a decreasing sequence, i.e. Part b) of Theorem 5.104.

5.6. n-Fold Binary Operations

Proposition 5.105. *The following sentences are true for any set X and any binary operation $\odot$ on X such that X contains the neutral element e with respect to $\odot$.*

a) For any $n \in \mathbb{N}$ and any sequence $s = (a_i \mid i \in \{1, \ldots, n^+\})$ in X, there exists the unique function

$$f : \{0, \ldots, n\} \times X \to X, \quad (i, x) \mapsto x \odot a_{i^+}. \tag{5.382}$$

b) Then, there exists the unique sequence $u = (u_i \mid i \in \{0, \ldots, n^+\})$ in X whose terms are defined by

$$(1)\ \ u_0 \ \ = e, \tag{5.383}$$

$$(2)\ \ u_{i^+} = f(i, u_i) = u_i \odot a_{i^+} \quad \text{for any } i \in \{0, \ldots, n\}. \tag{5.384}$$

Proof. We let X, $\odot$, n and s be arbitrary, assume that $\odot$ is a binary operation on X such that the identity element e in X with respect to $\odot$ exists, assume that n is a natural number, and assume moreover that $s = (a_i \mid i \in \{1, \ldots, n^+\})$ is a sequence in X with domain $\{1, \ldots, n^+\}$.

Concerning a), let us first verify

$$\forall z\, (z \in \{0, \ldots, n\} \times X \Rightarrow \exists! y\, (\exists i, x\ (z = (i, x)\ \wedge\ y = x \odot a_{i^+}))). \tag{5.385}$$

We take an arbitrary element z in $\{0, \ldots, n\} \times X$. Regarding the existential part, we notice that $z \in \{0, \ldots, n\} \times X$ implies by definition of the Cartesian product of two sets that there exist an element in $\{0, \ldots, n\}$, say $\bar{i}$, and an element in X, say $\bar{x}$, with $z = (\bar{i}, \bar{x})$. Here, $\bar{i} \in \{0, \ldots, n\}$ implies $\bar{i} \leq_{\mathbb{N}} n$ with (4.180), which in turn gives $\bar{i}^+ \leq_{\mathbb{N}} n^+$ due to (4.163), and this finding yields $\bar{i}^+ \in \{1, \ldots, n^+\}$ $[= \mathrm{dom}(s)]$ according to (4.275) and the assumption that s is a sequence with domain $\{1, \ldots, n^+\}$. The latter finding implies now with the Function Criterion that there exists the unique value/term $\bar{a} = a_{\bar{i}^+}$ of that sequence in X. Together with the previously established $\bar{x} \in X$, this gives $(\bar{x}, a_{\bar{i}^+}) \in X \times X$ $[= \mathrm{dom}(\odot)]$, so that there exists the unique value $\bar{y} = \bar{x} \odot a_{\bar{i}^+}$ in X (using the Function Criterion with respect to the binary operation $\odot$), proving the existential part of the uniquely existential sentence in (5.385). Now, it may not be obvious that this value $\bar{y}$ is uniquely determined by z. To verify its uniqueness, we let y and y' be arbitrary and assume

$$\exists i, x\ (z = (i, x)\ \wedge\ y = x \odot a_{i^+})\ \wedge\ \exists i, x\ (z = (i, x)\ \wedge\ y' = x \odot a_{i^+})$$

to be true. Thus there exist elements, say $\bar{i}$ and $\bar{x}$, with $z = (\bar{i}, \bar{x})$ and $y = \bar{x} \odot a_{\bar{i}^+}$, and there exist elements, say $\bar{i}'$ and $\bar{x}'$, with $z = (\bar{i}', \bar{x}')$ and $y' = \bar{x}' \odot a_{\bar{i}'^+}$. Then, substitution yields $(\bar{i}, \bar{x}) = (\bar{i}', \bar{x}')$ and consequently $\bar{i} = \bar{i}'$ as well as $\bar{x} = \bar{x}'$ with (3.3). Substitution based on these equations now gives

$$(y =)\ \bar{x} \odot a_{\bar{i}^+} = \bar{x}' \odot a_{\bar{i}'^+}\ (= y'),$$

so that we obtain indeed $y = y'$, which proves the uniqueness part of the uniquely existential sentence in (5.385). As z is arbitrary, we may therefore conclude that (5.385) holds. Then, there exists because of Theorem 3.160 a unique function f with domain $\{0, \ldots, n\} \times X$ such that

$$\forall z\, (z \in \{0, \ldots, n\} \times X \Rightarrow \exists i, x\ (z = (i, x) \wedge f(i, x) = x \odot a_{i^+})).$$

This shows that every ordered pair $(i, x) \in \{0, \ldots, n\} \times X$ is mapped by f to the value $x \odot a_{i^+}$. To verify that X is a codomain of f, we demonstrate that the range of f is included in X. For this purpose, we let $y \in \mathrm{ran}(f)$ be arbitrary, so that there exists (by definition of a range) an element, say $\bar{z}$, with $(\bar{z}, y) \in f$. On the one hand, we may write this as $y = f(\bar{z})$. On the other hand, this implies by definition of a domain that $\bar{z} \in \mathrm{dom}(f)$ holds, so that $\bar{z} \in \{0, \ldots, n\} \times X$. By definition of a Cartesian product, there then exists an element of $\{0, \ldots, n\}$, say $\bar{i}$, and an element of X, say $\bar{x}$, such that $\bar{z} = (\bar{i}, \bar{x})$. With this equation, it follows from the previously obtained $y = f(\bar{z})$ with the definition of the functions f and $\odot$ that

$$y = f(\bar{z}) = f(\bar{i}, \bar{x}) = \bar{x} \odot a_{\bar{i}^+}\ (\in X),$$

is true. We thus showed that $y \in \mathrm{ran}(f)$ implies $y \in X$; since y is arbitrary, it then follows with the definition of a subset that the range of f is indeed included in X, so that X is a codomain of f. This completes the proof that the function f in (5.382) exists uniquely.

Concerning b), we may apply the Recursion Theorem for initial segments with respect to the counting domain $(\mathbb{N}, s^+, 0)$ to infer from a) the unique existence of the sequence $u = (u_i \,|\, i \in \{0, \ldots, n^+\})$ in X satisfying (5.383) – (5.384), where we use the fact that the identity e is an element of X. Since X and $\odot$ were arbitrary, we therefore conclude that the proposition is true. □

Notation 5.13. For any set X, for any binary operation $\odot$ on X such that X contains the neutral element e with respect to $\odot$, for any $n \in \mathbb{N}$ and for any sequence $s = (a_i \,|\, i \in \{1, \ldots, n^+\})$ in X, we will write for the recursively defined terms of the sequence $u = (u_i \,|\, i \in \{0, \ldots, n^+\})$ also

$$\bigodot_{j=1}^{i} a_j = u_i. \tag{5.386}$$

Thus, we may write in particular

$$\bigodot_{j=1}^{0} a_j = u_0 \;=\; e \tag{5.387}$$

$$\bigodot_{j=1}^{n^+} a_j = u_{n^+} \;=\; u_n \odot a_{n^+} \;=\; \left(\bigodot_{j=1}^{n} a_j \right) \odot a_{n^+}. \tag{5.388}$$

Notation 5.14. For any set X, for any binary operation $\odot$ on X such that X contains the neutral element e with respect to $\odot$, for any $m \in \mathbb{N}$ and for any sequence $s = (a_i \,|\, i \in \{1, \ldots, m\})$ in X, we write in case of $m = 0$

$$\bigodot_{i=1}^{0} a_i = e. \tag{5.389}$$

In case of $m \neq 0$, there exists because of (4.39) a particular $n \in \mathbb{N}$ with $m = n^+$, so that we may write $s = (a_i \,|\, i \in \{1, \ldots, n^+\})$ and then (because of Proposition 5.105)

$$\bigodot_{i=1}^{m} a_i = \bigodot_{j=1}^{n^+} a_j. \tag{5.390}$$

Furthermore, we will abbreviate "for any sequence $s = (a_i \,|\, i \in \{1, \ldots, m\})$ in X" by "for any $a_1, \ldots, a_m \in X$".

Exercise 5.44. Verify the following sentences for any set X and any binary operation $\odot$ on X such that X contains the neutral element e w.r.t. $\odot$.

a) For any $a_1 \in X$, it is true that

$$\bigodot_{i=1}^{1} a_i = a_1. \tag{5.391}$$

b) For any $a_1, a_2 \in X$, it is true that

$$\bigodot_{i=1}^{2} a_i = a_1 \odot a_2. \tag{5.392}$$

c) For any $a_1, a_2, a_3 \in X$, it is true that

$$\bigodot_{i=1}^{3} a_i = (a_1 \odot a_2) \odot a_3. \tag{5.393}$$

d) For any $a_1, \ldots, a_{n+1} \in X$, it is true that

$$\bigodot_{i=1}^{n+1} a_i = \left(\bigodot_{i=1}^{n} a_i \right) \odot a_{n+1}. \tag{5.394}$$

(Hint: Use (2.291), (2.292), (2.293), (5.388), (5.387), (5.384), (5.90), and (5.217).)

Proposition 5.106. *For any set X, for any binary operation $\odot$ on X such that X contains the neutral element e with respect to $\odot$, and for any $m \in \mathbb{N}$, it is true that there exists the unique function*

$$\bigodot_{i=1}^{m} : X^{\{1,\ldots,m\}} \to X, \quad (a_i \,|\, i \in \{1, \ldots, m\}) \mapsto \bigodot_{i=1}^{m} a_i. \tag{5.395}$$

Proof. We let X, $\odot$ and m be arbitrary such that $\odot$ is a binary operation on X and such that $m \in \mathbb{N}$ holds. We now apply Function definition by replacement and verify

$$\forall s \, (s = (a_i \,|\, i \in \{1, \ldots, m\}) \in X^{\{1,\ldots,m\}} \Rightarrow \exists! y \, (y = \bigodot_{i=1}^{m} a_i)). \tag{5.396}$$

To do this, we let $s = (a_i \,|\, i \in \{1, \ldots, m\})$ be an arbitrary sequence in X. In case of $m = 0$, we obtain in view of Notation 5.14 the element $\bigodot_{i=1}^{0} a_i = e$ (in X), so that the uniquely existential sentence follows to be true with (1.109). In case of $m \neq 0$, the notation (5.390) shows that $\bigodot_{i=1}^{m} a_i$ is also a uniquely specified element (of X), and therefore the uniquely existential sentence is again true. Since s is arbitrary, we may therefore conclude that the universal sentence (5.396) is true, which implies the existence of a unique function $\bigodot_{i=1}^{m}$ with domain $X^{\{1,\ldots,m\}}$ such that

$$\forall s \, (s = (a_i \,|\, i \in \{1, \ldots, m\}) \in X^{\{1,\ldots,m\}} \Rightarrow \bigodot_{i=1}^{m}(s) = \bigodot_{i=1}^{m} a_i)$$

holds. We already showed that any value of this function is in X, so that we established the mapping (5.395). As X, $\odot$ and m were initially arbitrary, we may therefore infer from this the truth of the proposition. □

Definition 5.21 (n-fold binary operations). For any set X, for any binary operation $\odot$ on X such that the neutral element e of X with respect to $\odot$ exists, and for any $n \in \mathbb{N}$, we call the function

$$\bigodot_{i=1}^{n} : X^{\{1,\ldots,n\}} \to X, \quad (a_i \,|\, i \in \{1, \ldots, n\}) \mapsto \bigodot_{i=1}^{n} a_i. \tag{5.397}$$

the *n-fold repeated binary operation* on X.

The concept of an n-fold binary operation may be applied to the join and meet of a lattice.

Definition 5.22 (n-fold repeated join & meet). For any set X, for any $n \in \mathbb{N}$, and

(1) for any lattice $(X, \sqcup, \sqcap, \leq)$ such that the neutral element of X with respect to $\sqcup$ exists, we call

$$\sqcup_{i=1}^{n} \tag{5.398}$$

the *n-fold repeated join* on X.

(2) for any lattice $(X, \sqcup, \sqcap, \leq)$ such that the neutral element of X with respect to $\sqcap$ exists, we call

$$\sqcap_{i=1}^{n} \tag{5.399}$$

the *n-fold repeated meet* on X.

Proposition 5.107. *For any lattice $(X, \sqcup, \sqcap, \leq)$ such that the neutral elements of X both with respect to $\sqcup$ and $\sqcap$ exist, for any positive natural number n and for any sequence $s = (a_i \,|\, i \in \{1, \ldots, n\})$ it is true that*

a) the n-fold join is identical with the supremum of the range of $(a_i \,|\, i \in \{1, \ldots, n\})$,

b) the n-fold meet is identical with the infimum of the range of $(a_i \,|\, i \in \{1, \ldots, n\})$.

Proof. We let X, $\sqcup$, $\sqcap$ and $\leq$ be arbitrary sets such that $\leq$ is a reflexive partial ordering of X, such that $\sqcup$ is the join and $\sqcap$ the meet on X (with respect to $\sqcup$ and $\sqcap$, respectively), and such that $(X, \sqcup, \sqcap, \leq)$ is a lattice containing the neutral elements with respect to $\sqcup$ and $\sqcap$. To prove a), we verify

$$\forall n\, (n \in \mathbb{N}_+ \Rightarrow \forall s\, (s \in X^{\{1,\ldots,n\}} \Rightarrow \sqcup_{i=1}^{n} s(i) = \sup \operatorname{ran}(s))) \tag{5.400}$$

where we use the usual sequence notation $s = (a_i \,|\, i \in \{1, \ldots, n\})$, so that we write $s(i) = a_i$ for any $i \in \{1, \ldots, n\}$. For this purpose, we carry out a proof by mathematical induction. Concerning the base case ($n = 1$), we let s be arbitrary in $X^{\{1,\ldots,1\}}$, so that the domain of s equals the singleton $\{1\} = \{1, \ldots, 1\}$ (according to Notation 4.4). Therefore, we see in light of Proposition 3.159 that the sequence/function s is the singleton $\{(1, s(1))\} = \{(1, a_1)\}$. Furthermore, s is a bijection with codomain/range $\{a_1\}$ due to Corollary 3.202, so that $\operatorname{ran}(s) = \{a_1\}$ holds. We then obtain the equations

$$\sqcup_{i=1}^{n} s(i) = \sqcup_{i=1}^{1} a_i = a_1 = \sup\{a_1\} = \sup \operatorname{ran}(s)$$

by applying substitution, Exercise 5.44, Corollary 3.106 and finally again substitution. Thus, the proof of the base case is complete; regarding the induction step, we let n be arbitrary in $\mathbb{N}_+$, assume the universal sentence

$$\forall s\,(s \in X^{\{1,\ldots,n\}} \Rightarrow \sqcup_{i=1}^{n} s(i) = \sup \operatorname{ran}(s))) \tag{5.401}$$

to be true, and we show that this induction assumption implies the truth of

$$\forall s\,(s \in X^{\{1,\ldots,n^+\}} \Rightarrow \sqcup_{i=1}^{n^+} s(i) = \sup \operatorname{ran}(s))). \tag{5.402}$$

To prove this universal sentence, we take an arbitrary set s and assume that $s \in X^{\{1,\ldots,n^+\}}$ holds, so that we may write s in sequence notation as $s = (a_i \,|\, i \in \{1,\ldots,n^+\})$. To show that $\sqcup_{i=1}^{n^+} s(i)$ is the supremum of $\operatorname{ran}(s)$, we utilize the Characterization of the supremum and establish first $\sqcup_{i=1}^{n^+} s(i)$ as an upper bound for $\operatorname{ran}(s)$. Thus, our task consists in the verification of the universal sentence

$$\forall y\,(y \in \operatorname{ran}(s) \Rightarrow y \leq \sqcup_{i=1}^{n^+} s(i)). \tag{5.403}$$

We let y be arbitrary such that $y \in \operatorname{ran}(s)$ holds. By definition of a range, there exists then a constant, say $\bar{k}$, satisfying $(\bar{k}, y) \in s$, which we may write also as $y = s(\bar{k}) = a_{\bar{k}}$. Moreover, we obtain $\bar{k} \in \{1,\ldots,n^+\}$ $[= \operatorname{dom}(s)]$ with the definition of a domain, and this finding gives $\bar{k} \in \{1,\ldots,n\} \cup \{n^+\}$ with (4.241). Therefore, the disjunction of $\bar{k} \in \{1,\ldots,n\}$ and $\bar{k} \in \{n^+\}$ is true by definition of the intersection of two sets. Based on this disjunction, we now prove the inequality $y \leq \sqcup_{i=1}^{n^+} s(i)$ by cases. Let us rewrite this inequality as

$$y \leq \sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\} \quad [= (\sqcup_{i=1}^{n} a_i) \sqcup a_{n^+}],$$

according to the definition of the join (and by using Exercise 5.44d)). Here, the supremum $\sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\}$ is evidently an upper bound for the pair $\{\sqcup_{i=1}^{n} a_i, a_{n^+}\}$, so that we may apply the Characterization of upper bounds for pairs to obtain the two inequalities

$$\sqcup_{i=1}^{n} a_i \leq \sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\}, \tag{5.404}$$

$$a_{n^+} \leq \sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\}. \tag{5.405}$$

Let us return to the proof by cases and let us consider first the case of $\bar{k} \in \{1,\ldots,n\}$. Here, we may view $\{1,\ldots,n\}$ as the domain of the sequence $(a_i \,|\, i \in \{1,\ldots,n\})$ in X, so that $y = a_{\bar{k}}$ is evidently a term and thus an element of the range of that sequence. Consequently, the n-ary join $\sqcup_{i=1}^{n} a_i$ follows to be the supremum and thus to be an upper bound for the range of $(a_i \,|\, i \in \{1,\ldots,n\})$ because of the induction assumption (5.401), so that $y \leq \sqcup_{i=1}^{n} a_i$ holds. Together with (5.404), this inequality implies $y \leq \sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\}$ since the partial ordering $\leq$ is transitive. In the other case of $\bar{k} \in \{n^+\}$, we obtain first $\bar{k} = n^+$ with (2.169) and therefore $y = a_{\bar{k}} = a_{n^+}$. Consequently, the inequality (5.405) yields via substitution again $y \leq \sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\}$, completing the proof by cases of $y \leq \sqcup_{i=1}^{n^+} s(i)$. As y was arbitrary, we may therefore conclude that the universal sentence (5.403) is true, which means that we indeed established $\sqcup_{i=1}^{n^+} s(i)$ as an upper bound for $\mathrm{ran}(s)$.

To establish the second part of the Characterization of the supremum, we take an arbitrary S' such that S' is an upper bound for $\mathrm{ran}(s)$, i.e. such that

$$\forall y\,(y \in \mathrm{ran}(s) \Rightarrow y \leq S'), \tag{5.406}$$

and we show that $\sqcup_{i=1}^{n^+} s(i) \leq S'$ follows to be true. Using again the definition of a join and Exercise 5.44d)), we may write the preceding inequality as $\sup\{\sqcup_{i=1}^{n} a_i, a_{n^+}\} \leq S'$, which is also equivalent to the conjunction of $\sqcup_{i=1}^{n} a_i \leq S'$ and $a_{n^+} \leq S'$ in view of Exercise 3.45. To demonstrate the truth of this conjunction, we consider again the sequence $(a_i \,|\, i \in \{1, \ldots, n\})$ (in X). Since $n < n^+$ holds with (4.153), which inequality evidently implies $n \leq n^+$, we see in light of Corollary 4.87 that the range of the sequence $(a_i \,|\, i \in \{1, \ldots, n\})$ is included in the range of the sequence $(a_i \,|\, i \in \{1, \ldots, n^+\})$. Therefore, since the range of the latter sequence is bounded from above by S', we may apply Proposition 3.94 to infer that S' is also an upper bound for the range of the sequence $(a_i \,|\, i \in \{1, \ldots, n\})$. According to the induction assumption, $\sqcup_{i=1}^{n} a_i$ is the least upper bound, so that $\sqcup_{i=1}^{n} a_i \leq S'$ is true, as desired. Furthermore, a_{n^+} is clearly an element of the range of the sequence $s = (a_i \,|\, i \in \{1, \ldots, n^+\})$, so that (5.406) yields also the desired second part $a_{n^+} \leq S'$. We thus proved $\sqcup_{i=1}^{n^+} s(i) \leq S'$ and established therefore $\sqcup_{i=1}^{n^+} s(i)$ as the supremum of $\mathrm{ran}(s)$. Since s was arbitrary, we may infer from this the truth of the universal sentence (5.402); as n is also arbitrary, we may further conclude that the induction step holds, alongside the base case. Finally, because the sets X, $\sqcup$, $\sqcap$ and $\leq$ were initially arbitrary, Part a) of the proposition follows to be true. □

Exercise 5.45. Establish Part b) of Proposition 5.107.

Corollary 5.108. *For any lattice $(X, \sqcup, \sqcap, \leq)$ such that the neutral elements of X both with respect to the join and meet exist, it is true that the supremum and the infimum of any finite subset of X exist.*

Proof. We take arbitrary sets X, $\sqcup$, $\sqcap$, $\leq$ and A be arbitrary sets, assume that $(X, \sqcup, \sqcap, \leq)$ is a lattice such that X contains the neutral elements with respect to $\sqcup$ and $\sqcap$, assume that $A \subseteq X$ holds, and assume moreover that A

is finite. Consequently, there exist a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to A, say $\bar{c}$. Furthermore, the bijection $\bar{c}$ is in particular a surjection, so that $A = \operatorname{ran}(\bar{c})$ holds. Here, we see in view of the initial assumption $A \subseteq X$ that X is a codomain of $\bar{c}$. Thus, we may write the function $\bar{c}$ as the sequence $(a_i \,|\, i \in \{1, \ldots, \bar{n}\})$ in X, so that the preceding proposition gives for the supremum and the infimum of the range of that sequence, that is, for the supremum and the infimum of the set A

$$\begin{aligned} \sup A = \sup \operatorname{ran}(\bar{c}) &= \sqcup_{i=1}^{\bar{n}} a_i, \\ \inf A = \inf \operatorname{ran}(\bar{c}) \ &= \sqcap_{i=1}^{\bar{n}} a_i. \end{aligned}$$

Thus, the supremum and the infimum of A exist, and since X, $\sqcup$, $\sqcap$, $\leq$ and A were arbitrary, we may therefore conclude that the proposition holds, as claimed. $\square$

Definition 5.23 ($\boldsymbol{n}$-fold addition & multiplication, $\boldsymbol{n}$-fold sum & product). For any set X, any $n \in \mathbb{N}$, and

(1) for any addition $+$ on X such that the zero element 0_X exists, we call

$$\sum_{i=1}^{n} \tag{5.407}$$

the *n-fold addition* on X, and any of its values an *n-fold sum*.

(2) for any multiplication $\cdot$ on X such that the unity element 1_X exists, we call

$$\prod_{i=1}^{n} \tag{5.408}$$

the *n-fold multiplication* on X, and any of its values an *n-fold product*.

We now apply these notations to the findings of Exercise 5.44.

Corollary 5.109. *The following sentences hold for any set X, for any addition $+$ on X such that X contains the zero element 0_X, and for any multiplication on X such that X contains the unity element 1_X.*

a) It is true that

$$\sum_{i=1}^{0} a_i = 0_X, \tag{5.409}$$

$$\prod_{i=1}^{0} a_i = 1_X. \tag{5.410}$$

b) For any $a_1 \in X$*, it is true that*

$$\sum_{i=1}^{1} a_i = a_1, \tag{5.411}$$

$$\prod_{i=1}^{1} a_i = a_1. \tag{5.412}$$

c) For any $a_1, a_2 \in X$*, it is true that*

$$\sum_{i=1}^{2} a_i = a_1 + a_2, \tag{5.413}$$

$$\prod_{i=1}^{2} a_i = a_1 \cdot a_2. \tag{5.414}$$

d) For any $a_1, a_2, a_3 \in X$*, it is true that*

$$\sum_{i=1}^{3} a_i = (a_1 + a_2) + a_3, \tag{5.415}$$

$$\prod_{i=1}^{3} a_i = (a_1 \cdot a_2) \cdot a_3. \tag{5.416}$$

e) For any $n \in \mathbb{N}$ *and any* $a_1, \ldots, a_{n+1} \in X$*, it is true that*

$$\sum_{i=1}^{n+1} a_i = \left(\sum_{i=1}^{n} a_i\right) + a_{n+1}, \tag{5.417}$$

$$\prod_{i=1}^{n+1} a_i = \left(\prod_{i=1}^{n} a_i\right) \cdot a_{n+1}. \tag{5.418}$$

As a first important application of n-fold addition, we establish the following kind of function associated with a given matrix and vector.

Theorem 5.110 (Specification of the standard matrix-vector product). *The following sentences are true for any positive natural numbers* m *and* n*, any set* Y*, any addition* $+_Y$ *on* Y *such that the zero element* 0_Y *exists, any multiplication* $\cdot_Y$ *on* Y*, any* m*-by-*n *matrix* $\boldsymbol{A}$ *with values in* Y*, and any* n*-vector* $\boldsymbol{x}$ *in* Y*:*

a) For any $i \in \{1, \ldots, m\}$ the n-tuple

$$h_i = (\boldsymbol{A}((i,k)) \cdot_Y x_k \,|\, k \in \{1, \ldots, n\}) \tag{5.419}$$

exists uniquely in Y.

b) There exists a unique m-vector $\boldsymbol{y}$ in Y whose values are defined by

$$\forall i \, (i \in \{1, \ldots, m\} \Rightarrow y_i = \sum_{k=1}^{n} (\boldsymbol{A}((i,k)) \cdot_Y x_k)). \tag{5.420}$$

Exercise 5.46. Establish Theorem 5.110.
(Hint: Apply Function definition by replacement twice.)

Definition 5.24 (Standard matrix-vector product). For any positive natural numbers m and n, any set Y, any addition $+_Y$ on Y such that the zero element 0_Y exists, any multiplication $\cdot_Y$ on Y, any m-by-n matrix $\boldsymbol{A}$ with values in Y, and any n-vector $\boldsymbol{x}$ in Y, we call the m-vector $\boldsymbol{y}$ defined by (5.420) the *standard matrix-vector product* of $\boldsymbol{A}$ and $\boldsymbol{x}$, symbolically

$$\boldsymbol{y} = \boldsymbol{A}\boldsymbol{x} = \boldsymbol{A} \cdot \boldsymbol{x}. \tag{5.421}$$

Theorem 5.111 (Matrix-vector notation for n-fold sums). *The following equations hold for any positive natural number n, any set Y, any addition $+_Y$ with zero element 0_Y, any multiplication $\cdot_Y$ with identity element 1_Y, and any n-vector $\boldsymbol{x}$ in Y.*

$$\begin{bmatrix} 1_Y & \cdots & 1_Y \end{bmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = \left(\sum_{k=1}^{n} x_k \right). \tag{5.422}$$

Proof. We take an arbitrary positive natural number n, an arbitrary set Y as well as an arbitrary addition $+_Y$ on Y such that the zero element 0_Y in Y exists, an arbitrary multiplication $\cdot_Y$ on Y, and an arbitrary n-vector $\boldsymbol{x}$ in Y. Defining the 1-by-n matrix (i.e., the n-dimensional row vector) $\boldsymbol{a} = \begin{bmatrix} 1_Y & \cdots & 1_Y \end{bmatrix} = g_{1_Y}$ to be the constant function on $\{1\} \times \{1, \ldots, n\}$ with value 1_Y, we obtain for the product of $\boldsymbol{a}$ and $\boldsymbol{x}$ the 1-vector $\boldsymbol{y}$ with the single value

$$y_1 = \sum_{k=1}^{n} (\boldsymbol{a}((1,k)) \cdot_Y x_k) = \sum_{k=1}^{n} (1_Y \cdot_Y x_k) = \sum_{k=1}^{n} x_k$$

using the definition of a unity element. Since n, Y, $+_Y$, $\cdot_Y$ and $\boldsymbol{x}$ were initially all arbitrary, we may therefore conclude that the stated universal sentence holds. $\square$

Recalling the facts (1) that any addition on a set Y with zero element gives rise to a corresponding pointwise addition of functions in a set Y^X also with zero element, we may establish the n-fold addition on such sets of functions, and moreover establish the following compatibility property.

Proposition 5.112. *The n-fold addition of functions in a set Y^X is compatible with the n-fold addition of the corresponding function values, that is,*

$$\forall x \,(x \in X \Rightarrow \left(\sum_{i=1}^{n} f_i\right)(x) = \sum_{i=1}^{n} f_i(x)) \tag{5.423}$$

holds for any $n \in \mathbb{N}$ and any n-tuple $f = (f_i \,|\, i \in \{1,\ldots,n\})$ of functions in Y^X.

Proof. We let X, Y and $+_Y$ be arbitrary sets such that $+_Y$ is an addition on Y and such that the zero element (0_Y) of Y exists. We carry out a proof by mathematical induction. Concerning the base case $(n = 0)$, we let f be an arbitrary 0-tuple $(f_i\, i \in \{1,\ldots,0\})$ and x an arbitrary element of X. We obtain then the equations

$$\left(\sum_{i=1}^{0} f_i\right)(x) = g_{0_Y}(x) = 0_Y = \sum_{i=1}^{0} f_i(x),$$

using (5.409) in connection with the fact that the zero element 0_Y defines the zero element of Y^X with respect to $+_{Y^X}$, which is the constant function g_{0_Y} on X with value 0_Y, according to Proposition 5.19). Since x was arbitrary, we may therefore conclude that the universal sentence (5.423) is true in the base case. To establish the induction step, we let n be an arbitrary natural number, make the induction assumption that (5.423) holds for any any n-tuple $f = (f_i \,|\, i \in \{1,\ldots,n\})$ of functions in Y^X, and we show that

$$\forall x \,(x \in X \Rightarrow \left(\sum_{i=1}^{n+1} f_i\right)(x) = \sum_{i=1}^{n+1} f_i(x))$$

follows to be true for any $(n+1)$-tuple $f = (f_i\, i \in \{1,\ldots,n+1\})$ of functions in Y^X. To do this, we let f be an arbitrary $(n+1)$-tuple of that kind, and x an arbitrary element of X. We note that the f gives rise to the $(n+1)$-tuple of function values $f^{(x)} = (f_i(x)\, i \in \{1,\ldots,n+1\})$ according to Proposition

3.231. We then obtain the equations

$$\left(\sum_{i=1}^{n+1} f_i\right)(x) = \left(\sum_{i=1}^{n} f_i + f_{n+1}\right)(x) = \left(\sum_{i=1}^{n} f_i\right)(x) + f_{n+1}(x)$$
$$= \sum_{i=1}^{n} f_i(x) + f_{n+1}(x) = \sum_{i=1}^{n+1} f_i(x)$$

with (5.417), the definition of the pointwise addition for functions, the induction assumption, and finally again (5.417). As x, f and n were arbitrary, we may therefore conclude that the induction step holds, besides the base case. Then, since X, Y and $+_Y$ were also arbitrary, the proposed universal sentence follows to be true. □

5.6.1. Basic laws for n-fold binary operations

Theorem 5.113 ($\boldsymbol{n}$-fold repeated addition & multiplication of the sum & product of two sequences). *It is true*

a) *for any commutative semigroup $(X, +)$ containing the zero element 0_X, for any $n \in \mathbb{N}$, any $a_1, \ldots, a_n \in X$ and any $b_1, \ldots, b_n \in X$ that*

$$\sum_{i=1}^{n}(a_i + b_i) = \left(\sum_{i=1}^{n} a_i\right) + \left(\sum_{i=1}^{n} b_i\right). \tag{5.424}$$

b) *for any commutative semigroup $(X, \cdot)$ containing the unity element 1_X, for any $n \in \mathbb{N}$, any $a_1, \ldots, a_n \in X$ and any $b_1, \ldots, b_n \in X$ that*

$$\prod_{i=1}^{n}(a_i \cdot b_i) = \left(\prod_{i=1}^{n} a_i\right) \cdot \left(\prod_{i=1}^{n} b_i\right). \tag{5.425}$$

Proof. Concerning a), we let X and $+$ be arbitrary sets and assume that $(X, +)$ is a commutative semigroup which contains the neutral element 0_X with respect to the addition $+$ on X. To establish the equation (5.424) for any $n \in \mathbb{N}$, any $a_1, \ldots, a_n \in X$ and any $b_1, \ldots, b_n \in X$, we prove

$$\begin{aligned} &\forall n\,(n \in \mathbb{N} \Rightarrow \forall s, t\,(s, t \in X^{\{1,\ldots,n\}} \\ &\quad \Rightarrow \sum_{i=1}^{n}(s(i) + t(i)) = \left[\sum_{i=1}^{n} s(i)\right] + \left[\sum_{i=1}^{n} t(i)\right])) \end{aligned} \tag{5.426}$$

by means of mathematical induction. In the base case ($n = 0$), we let s and t be arbitrary sets and assume $s, t \in X^{\{1,\ldots,0\}}$, so that we may write s and t

in sequence notation as $s = (a_i \,|\, i \in \{1,\ldots,0\})$ and $t = (b_i \,|\, i \in \{1,\ldots,0\})$. Furthermore, the preceding assumption allows us to form the new sequence $h = s +_{X^{\{1,\ldots,0\}}} t$ because of Theorem 5.6, which sequence satisfies $h(i) = s(i) + t(i)$ for any $i \in \{1,\ldots,0\}$. Thus, the 0-fold repeated additions are specified for the sequences h, s and t, and we obtain

$$\begin{aligned}\sum_{i=1}^{n}(s(i)+t(i)) &= \sum_{i=1}^{0}[s(i)+t(i)] = 0_X = 0_X + 0_X \\ &= \left[\sum_{i=1}^{0} s(i)\right] + \left[\sum_{i=1}^{0} t(i)\right] = \left[\sum_{i=1}^{n} s(i)\right] + \left[\sum_{i=1}^{n} t(i)\right]\end{aligned}$$

by applying substitution based on the assumed equation $n = 0$, then Corollary 5.109a), the definition of a neutral element, again Corollary 5.109a), and finally again substitution based on $n = 0$. Consequently, the base case holds. To establish the induction step, we take an arbitrary $n \in \mathbb{N}$, make the induction assumption

$$\forall s,t\,(s,t \in X^{\{1,\ldots,n\}} \Rightarrow \sum_{i=1}^{n}(s(i)+t(i)) = \left[\sum_{i=1}^{n} s(i)\right] + \left[\sum_{i=1}^{n} t(i)\right]), \tag{5.427}$$

and show that the universal sentence

$$\forall s,t\,(s,t \in X^{\{1,\ldots,n^+\}} \Rightarrow \sum_{i=1}^{n^+}(s(i)+t(i)) = \left[\sum_{i=1}^{n^+} s(i)\right] + \left[\sum_{i=1}^{n^+} t(i)\right]) \tag{5.428}$$

follows to be true. For this purpose, we take arbitrary sequences s, t in $X^{\{1,\ldots,n^+\}}$, which we may then write also as $s = (a_i \,|\, i \in \{1,\ldots,n^+\})$ and $t = (b_i \,|\, i \in \{1,\ldots,n^+\})$. Therefore, the sequence $h = s +_{X^{\{1,\ldots,n^+\}}} t$ which satisfies $h(i) = s(i) + t(i)$ for any $i \in \{1,\ldots,n^+\}$ is uniquely determined according to Theorem 5.6, so that we obtain

$$\sum_{i=1}^{n^+}(s(i)+t(i)) = \left[\sum_{i=1}^{n}(s(i)+t(i))\right] + (s(n^+)+t(n^+)) \tag{5.429}$$

with Corollary 5.109e). Here, the n-fold addition may be viewed as being applied to the sequences $(a_i + b_i \,|\, i \in \{1,\ldots,n\})$, $(a_i \,|\, i \in \{1,\ldots,n\})$ and $(b_i \,|\, i \in \{1,\ldots,n\})$, so that we may apply substitution in connection with the induction assumption (5.427) to write equation (5.429) as

$$\sum_{i=1}^{n^+}(s(i)+t(i)) = \left(\left[\sum_{i=1}^{n} s(i)\right] + \left[\sum_{i=1}^{n} t(i)\right]\right) + (s(n^+)+t(n^+)).$$

As we assumed $(X, +)$ to be a commutative semigroup, which means that the addition on X is both commutative and associative, we may rewrite the preceding equation also as

$$\begin{aligned}
\sum_{i=1}^{n^+}(s(i)+t(i)) &= \left[\sum_{i=1}^{n} s(i)\right] + \left(\left[\sum_{i=1}^{n} t(i)\right] + (s(n^+)+t(n^+))\right) \\
&= \left[\sum_{i=1}^{n} s(i)\right] + \left(\left(\left[\sum_{i=1}^{n} t(i)\right] + s(n^+)\right) + t(n^+)\right) \\
&= \left[\sum_{i=1}^{n} s(i)\right] + \left(\left(s(n^+) + \left[\sum_{i=1}^{n} t(i)\right]\right) + t(n^+)\right) \\
&= \left[\sum_{i=1}^{n} s(i)\right] + \left(s(n^+) + \left(\left[\sum_{i=1}^{n} t(i)\right] + t(n^+)\right)\right) \\
&= \left(\left[\sum_{i=1}^{n} s(i)\right] + s(n^+)\right) + \left(\left[\sum_{i=1}^{n} t(i)\right] + t(n^+)\right)
\end{aligned}$$

Applying now Corollary 5.109e) to the two summands on the right-hand side of the last equation, we evidently obtain the equation stated in (5.428). Since s and t are arbitrary, we may therefore conclude that the universal sentence (5.428) is true; consequently, because n was also arbitrary, we may further conclude that the induction step also holds, so that the proof of the universal sentence (5.426) via mathematical induction is complete. Finally, as the sets X and $+$ were initially arbitrary as well, we may infer from this finding the truth of Part a) of the stated theorem. □

Exercise 5.47. Establish Part b) of Theorem 5.113.

Our next task is to prepare ourselves for generalizing the associativity of binary operations in semigroups to n-fold binary operations.

Notation 5.15. For any $m, n \in \mathbb{N}$ we write for the intermediate segment of $\mathbb{N}_+$ from the successor of m to n also

$$\{m+1, \ldots, n\} = \{m^+, \ldots, n\}. \tag{5.430}$$

Corollary 5.114. *For any set X, any $m, n \in \mathbb{N}$ and any sequence $s = (a_i \,|\, i \in \{1, \ldots, m+n\})$ in X, it is true that the restriction of s to the intermediate segment of $\mathbb{N}_+$ from $m+1$ to $m+n$ is a function from that intermediate segment to X, i.e.*

$$s \upharpoonright \{m+1, \ldots, m+n\} : \{m+1, \ldots, m+n\} \to X. \tag{5.431}$$

Proof. We let X, m, n and s be arbitrary sets, we assume $m, n \in \mathbb{N}$, and we assume that s is a sequence $(a_i \,|\, i \in \{1, \ldots, m+n\})$ in X. Here, $m, n \in \mathbb{N}$ yields $m + n \in \mathbb{N}$ because $+$ is a binary operation on $\mathbb{N}$. Therefore, the intermediate segment $\{m+1, \ldots, m+n\}$ is included in the initial segment $\{1, \ldots, m+n\}$ according to (4.298). As the sequence s is an element of $X^{\{1,\ldots,m+n\}}$, we may now apply Proposition 3.164 to see that the restriction $s \upharpoonright \{m+1, \ldots, m+n\}$ is an element of $X^{\{m+1,\ldots,m+n\}}$. Consequently, this restriction is a function as stated in (5.431); since X, m, n and s are arbitrary sets, we may therefore conclude that the proposed universal sentence is true. □

Notation 5.16. For any set X, for any $m, n \in \mathbb{N}$ and for any sequence $s = (a_i \,|\, i \in \{1, \ldots, m+n\})$ in X we also write for the restriction of s to the intermediate segment of $\mathbb{N}_+$ from $m+1$ to $m+n$

$$(a_i \,|\, i \in \{m+1, \ldots, m+n\}) = s \upharpoonright \{m+1, \ldots, m+n\}. \tag{5.432}$$

We now come to the important idea of 'translating' the domain of a sequence.

Proposition 5.115. *The following sentences are true for any $m, n \in \mathbb{N}$.*

a) There exists a unique function t with domain $\{1, \ldots, n\}$ such that

$$\forall j\,(j \in \{1, \ldots, n\} \;\Rightarrow\; t(j) = m +_{\mathbb{N}} j) \tag{5.433}$$

b) This function t is a bijection from $\{1, \ldots, n\}$ to $\{m+1, \ldots, m+n\}$, i.e.

$$t : \{1, \ldots, n\} \rightleftarrows \{m+1, \ldots, m+n\}. \tag{5.434}$$

c) Furthermore, the inverse function of t is a bijection

$$t^{-1} : \{m+1, \ldots, m+n\} \rightleftarrows \{1, \ldots, n\} \tag{5.435}$$

satisfying

$$\forall k\,(k \in \{m+1, \ldots, m+n\} \;\Rightarrow\; t^{-1}(k) = k -_{\mathbb{N}} m). \tag{5.436}$$

Proof. We let $m, n \in \mathbb{N}$ be arbitrary and apply within the proof of a) Function definition by replacement, by verifying

$$\forall j\,(j\{1, \ldots, n\} \Rightarrow \exists! y\,(y = m +_{\mathbb{N}} j)). \tag{5.437}$$

To do this, we let j be arbitrary and assume $j \in \{1, \ldots, n\}$ to be true. Since the addition on $\mathbb{N}$ is a binary operation on $\mathbb{N}$, we have that the sum

$m +_{\mathbb{N}} j$ is a natural number, and therefore the uniquely existential sentence follows to be true with (1.109). Because j is arbitrary, we may now conclude that the universal sentence (5.396) is true, which implies the existence of a unique function t with domain $\{1, \ldots, n\}$ such that (5.433) holds. To show that $\{m+1, \ldots, m+n\}$ is a codomain of t, we verify that the range of t is included in that intermediate segment, i.e.

$$\forall y\, (y \in \mathrm{ran}(t) \Rightarrow y \in \{m+1, \ldots, m+n\}). \tag{5.438}$$

For this purpose, we let y be arbitrary and assume $y \in \mathrm{ran}(t)$ to be true. Then, there exists by definition of a range a constant, say $\bar{k}$, such that $(\bar{k}, y) \in t$ holds, which we may write in function notation also as $y = t(\bar{k})$. Consequently, we obtain with the definition of a domain $\bar{k} \in \{1, \ldots, n\}$ [$=$ $\mathrm{dom}(t)$], which yields with (5.433) [$y =$] $t(\bar{k}) = m +_{\mathbb{N}} \bar{k}$. Furthermore, we see that there exists an element in $\{1, \ldots, n\}$, so that this initial segment of $\mathbb{N}_+$ is evidently nonempty. Thus, $\bar{k}, n \in \mathbb{N}_+$ holds by definition of an initial segment of $\mathbb{N}_+$, which yields the inequality $1 \leq_{\mathbb{N}} \bar{k}$ with (4.278). Moreover, the previously established $\bar{k} \in \{1, \ldots, n\}$ yields $\bar{k} \leq_{\mathbb{N}} n$ with (4.275). We may now apply the Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$ to the inequalities $1 \leq_{\mathbb{N}} \bar{k}$ and $\bar{k} \leq_{\mathbb{N}} n$, with the consequence that $1 + m \leq_{\mathbb{N}} \bar{k} + m$ and $\bar{k} + m \leq_{\mathbb{N}} n + m$ hold. In view of the Commutative Law for the addition on $\mathbb{N}$, we may write these inequalities also as $m + 1 \leq_{\mathbb{N}} m + \bar{k} \leq_{\mathbb{N}} m + n$. Thus, [$m + \bar{k} =$] $y \in \{m+1, m+n\}$ holds according to Proposition 4.62, so that the proof of the implication in (5.438) is complete. Since y is arbitrary, we may therefore conclude that (5.438) holds, which universal sentence then implies the truth of the desired inclusion $\mathrm{ran}(t) \subseteq \{m+1, \ldots, m+n\}$ with the definition of a subset. We thus showed that t is a function from $\{1, \ldots, n\}$ to $\{m+1, \ldots, m+n\}$, and because t satisfies (5.433), we now see that t is indeed the mapping (5.434).

Regarding b), we show first that t is an injection by applying the Injection Criterion, i.e. by verifying

$$\forall j, j'\, ([j, j'\{1, \ldots, n\} \wedge j \neq j'] \Rightarrow t(j) \neq t(j')). \tag{5.439}$$

We take arbitrary j and j' and assume $j, j'\{1, \ldots, n\}$ as well as $j \neq j'$ to be true. In view of the connexity of the standard linear ordering $<_{\mathbb{N}}$, the preceding inequality implies the truth of the disjunction $j <_{\mathbb{N}} j' \vee j' <_{\mathbb{N}} j$, which we use to prove $m +_{\mathbb{N}} j \neq m +_{\mathbb{N}} j'$ by cases. The first case $j <_{\mathbb{N}} j'$ implies $j +_{\mathbb{N}} m <_{\mathbb{N}} j' +_{\mathbb{N}} m$ with the Monotony Law for $+_{\mathbb{N}}$ and $<_{\mathbb{N}}$, so that we obtain $m +_{\mathbb{N}} j <_{\mathbb{N}} m +_{\mathbb{N}} j'$ by means of the commutativity of $+_{\mathbb{N}}$. In light of the Characterization of comparability with respect to the linear ordering $<_{\mathbb{N}}$, we now see that the truth of the preceding inequality implies that $m +_{\mathbb{N}} j = m +_{\mathbb{N}} j'$ is false, so that the desired $m +_{\mathbb{N}} j \neq m +_{\mathbb{N}} j'$

is true. Using the same arguments as in the first case, we obtain in the second case $j' <_{\mathbb{N}} j$ first $m +_{\mathbb{N}} j' <_{\mathbb{N}} m +_{\mathbb{N}} j$ and therefore $m +_{\mathbb{N}} j' \neq m +_{\mathbb{N}} j$, which we may write also in the desired form $m +_{\mathbb{N}} j \neq m +_{\mathbb{N}} j'$. Having thus completed the proof by cases, we observe now that the assumed $j, j'\{1, \ldots, n\}$ implies $t(j) = m +_{\mathbb{N}} j$ as well as $t(j') = m +_{\mathbb{N}} j'$ with (5.433), so that the preceding inequality becomes after substitutions $t(j) \neq t(j')$. As j and j' are arbitrary, we may therefore conclude that (5.439) is true, which means that t is indeed an injection.

Next, we show that $\{m + 1, \ldots, m + n\}$ is a codomain of the injection t, i.e. that the inclusion $\mathrm{ran}(t) \subseteq \{m + 1, \ldots, m + n\}$ holds. To do this, we utilize the definition of a subset and establish the equivalent universal sentence

$$\forall k\, (k \in \mathrm{ran}(t) \Rightarrow k \in \{m + 1, \ldots, m + n\}), \tag{5.440}$$

letting k be arbitrary and assuming $k \in \mathrm{ran}(t)$ to be true. By definition of a range, there exists then a particular constant $\bar{J}$ with $(\bar{J}, k) \in t$. On the one hand, this implies with the definition of a domain $\bar{J} \in \{1, \ldots, n\}$ $[= \mathrm{dom}(t)]$; observing that $\{1, \ldots, n\} = [0^+, n]$ holds according to (4.295) and (2.291), we thus have $1 \leq_{\mathbb{N}} \bar{J} \leq_{\mathbb{N}} n$, so that an application of the Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$ in connection with the commutativity of $+_{\mathbb{N}}$ yields

$$m +_{\mathbb{N}} 1 \;\leq_{\mathbb{N}}\; m +_{\mathbb{N}} \bar{J} \;\leq_{\mathbb{N}}\; m +_{\mathbb{N}} n.$$

Since we may write $(\bar{J}, k) \in t$ in function notation as $k = t(\bar{J})$ $[= m +_{\mathbb{N}} \bar{J}]$, the preceding inequalities imply via substitution

$$m +_{\mathbb{N}} 1 \;\leq_{\mathbb{N}}\; t(\bar{J}) \;\leq_{\mathbb{N}}\; m +_{\mathbb{N}} n$$

and therefore $t(\bar{J}) \in \{m +_{\mathbb{N}} 1, \ldots, m +_{\mathbb{N}} n\}$ with (4.290).. This finding proves the implication in (5.440), and as k was arbitrary, we may infer from this the truth of the universal sentence (5.440). Consequently, the inclusion $\mathrm{ran}(t) \subseteq \{m + 1, \ldots, m + n\}$ holds indeed, which shows that t is an injection with codomain $\{m + 1, \ldots, m + n\}$.

To establish the injection $t : \{1, \ldots, n\} \hookrightarrow \{m + 1, \ldots, m + n\}$ as a bijection, we may now apply the Surjection Criterion and verify accordingly

$$\forall k\, (k \in \{m + 1, \ldots, m + n\} \Rightarrow \exists j\, (t(j) = k)). \tag{5.441}$$

For this purpose, we let k be arbitrary and assume $k \in \{m+1, \ldots, m+n\}$, so that $k \in \mathbb{N}$ and

$$m +_{\mathbb{N}} 1 \;\leq_{\mathbb{N}}\; k \;\leq_{\mathbb{N}}\; m +_{\mathbb{N}} n \tag{5.442}$$

are true because of (4.290). Since $m <_{\mathbb{N}} m^+$ is true according to (4.153), we clearly have that $m \leq_{\mathbb{N}} m +_{\mathbb{N}} 1$ $[\leq_{\mathbb{N}} k]$ holds; the transitivity of the standard total ordering $\leq_{\mathbb{N}}$ gives then also $m \leq_{\mathbb{N}} k$. We may therefore apply the Monotony Law for $-_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$ to infer from (5.442) the truth of the inequalities

$$(m +_{\mathbb{N}} 1) -_{\mathbb{N}} m \ \leq_{\mathbb{N}} \ k -_{\mathbb{N}} m \ \leq_{\mathbb{N}} \ (m +_{\mathbb{N}} n) -_{\mathbb{N}} m.$$

Then, twofold application of (5.344) in connection with the commutativity of $+_{\mathbb{N}}$ yields the inequalities $1 \leq_{\mathbb{N}} k -_{\mathbb{N}} m \leq_{\mathbb{N}} n$, so that $k -_{\mathbb{N}} m \in \{1, \ldots, n\}$ [$= \mathrm{dom}(t)$] is evidently true. The corresponding function value of t follows to be

$$t(k -_{\mathbb{N}} m) = m +_{\mathbb{N}} (k -_{\mathbb{N}} m) = k, \tag{5.443}$$

which equations prove the desired existential sentence $\exists j\,(t(j) = k)$. As k was arbitrary, we may therefore conclude that the universal sentence (5.441) holds, completing the proof of the surjectivity of the injection $t : \{1, \ldots, n\} \hookrightarrow \{m+1, \ldots, m+n\}$. Thus, t is a bijection from $\{1, \ldots, n\}$ to $\{m+1, \ldots, m+n\}$, by definition.

Regarding c), we obtain the bijective inverse (5.435) of t immediately with the Bijectivity of inverse functions. To demonstrate that t^{-1} satisfies (5.436), we let $k \in \{m+1, \ldots, m+n\}$ be arbitrary, with the consequence that $k = t(k -_{\mathbb{N}} m)$ holds, according to (5.443). This equation in turn implies $k -_{\mathbb{N}} m = t^{-1}(k)$ with the Characterization of the function values of an inverse function, as desired. Because k was arbitrary, we may now further conclude that t^{-1} satisfies indeed the universal sentence (5.436). As m and n were initially also arbitrary, we may therefore infer from the truth of a) – c) the truth of the proposition. □

Corollary 5.116. *For any set X, for any $m, n \in \mathbb{N}$ and for any sequence $s = (a_i \,|\, i \in \{1, \ldots, m+n\})$ in X, it is true that the composition s' of the restricted sequence $(a_i \,|\, i \in \{m+1, \ldots, m+n\})$ and the function t in (5.434) constitutes the function*

$$[s' =]\ s \restriction \{m+1, \ldots, m+n\} \circ t : \{1, \ldots, n\} \to X, \quad i \mapsto a_{m+i}. \tag{5.444}$$

Proof. Letting X, m, n and s be arbitrary such that m and n are natural numbers and such that s is a sequence $(a_i \,|\, i \in \{1, \ldots, m+n\})$ in X, we may apply Proposition 3.178 to the functions (5.434) and (5.431) to see that the composition s' of $s \restriction \{m+1, \ldots, m+n\}$ and t is a function from $\{1, \ldots, n\}$ to X. Thus, we may consider this function s' to be the sequence $(a'_i \,|\, i \in \{1, \ldots, n\})$ (in X). Next, we verify

$$\forall i\,(i \in \{1, \ldots, n\} \Rightarrow a'_i = a_{m+i}), \tag{5.445}$$

letting i be arbitrary in $\{1, \ldots, n\}$ and observing the truth of the equations

$$\begin{aligned} a'_i &= s'(i) \\ &= [s \restriction \{m+1, \ldots, m+n\} \circ t](i) \\ &= s \restriction \{m+1, \ldots, m+n\}(t(i)) \\ &= s \restriction \{m+1, \ldots, m+n\}(m+i) \\ &= s(m+i) \\ &= a_{m+i} \end{aligned}$$

in light of the definitions of the sequences s' and s, the notation for compositions, and (3.567). As i is arbitrary, we may therefore conclude that the composition s' is indeed the function (5.444); since X, m, n and s were arbitrary, we may then further conclude that the proposed sentence is true. □

Notation 5.17. For any set X, for any binary operation $\odot$ on X such that X contains the neutral element e with respect to $\odot$, for any $m, n \in \mathbb{N}$ and for any sequence $s = (a_i \,|\, i \in \{1, \ldots, m+n\})$ in X, we also write

$$\bigodot_{i=m+1}^{m+n} a_i = \bigodot_{j=1}^{n} a'_j \quad \left[= \bigodot_{j=1}^{n} a_{m+j} \right], \tag{5.446}$$

where $s' = (a'_i \,|\, i \in \{1, \ldots, n\}) = (a_{m+i} \,|\, i \in \{1, \ldots, n\})$.

Lemma 5.117. *For any semigroup $(X, \odot)$ such that X contains the neutral element e with respect to $\odot$ and for any $m \in \mathbb{N}$, it is true that*

$$\forall n \, (n \in \mathbb{N} \Rightarrow \forall s \, (s \in X^{\{1,\ldots,m+n\}} \Rightarrow \left(\bigodot_{i=1}^{m} a_i \right) \odot \left(\bigodot_{i=m+1}^{m+n} a_i \right) = \bigodot_{i=1}^{m+n} a_i)). \tag{5.447}$$

Proof. We let X, $\odot$ and m be arbitrary sets, assume that $(X, \odot)$ is semigroup such that X contains the neutral element e with respect to $\odot$, and we assume that m is a natural number. We now apply a proof by mathematical induction with respect to n. Regarding the base case $(n = 0)$, we let s be an arbitrary set, assume that $s = (a_i \,|\, i \in \{1, \ldots, m+0\})$ is a sequence in X, and observe the truth of the equations

$$\left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+0} a_i\right) = \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{j=1}^{0} a'_j\right) = \left(\bigodot_{i=1}^{m} a_i\right) \odot e$$

$$= \bigodot_{i=1}^{m} a_i = \bigodot_{i=1}^{m+0} a_i,$$

applying (5.446) in connection with (5.432), (5.387), the definition of a neutral element, and substitution based on the equation $m = m + 0$ and the fact that 0 is the neutral element in $\mathbb{N}$ with respect to $+_{\mathbb{N}}$ according to Theorem 5.80. Consequently, we obtain after substitution based on $n = 0$ the desired equation (5.447); since s was initially an arbitrary set, we may therefore conclude that the base case holds.

Regarding the induction step, we let $n \in \mathbb{N}$ be arbitrary, make the induction assumption

$$\forall s\,(s \in X^{\{1,\ldots,m+n\}} \Rightarrow \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+n} a_i\right) = \bigodot_{i=1}^{m+n} a_i), \tag{5.448}$$

and show that this implies

$$\forall s\,(s \in X^{\{1,\ldots,m+(n+1)\}} \Rightarrow \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+(n+1)} a_i\right) = \bigodot_{i=1}^{m+(n+1)} a_i). \tag{5.449}$$

To prove the latter universal sentence, we let s be arbitrary and assume that $s = (a_i \,|\, i \in \{1,\ldots,m+(n+1)\})$ is a sequence in X, so that we obtain the sequence $s' = (a'_i \,|\, i \in \{1,\ldots,n+1\}) = (a_{m+i} \,|\, i \in \{1,\ldots,n+1\})$ and then the equations

$$
\begin{aligned}
\left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+(n+1)} a_i\right) &= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{j=1}^{n+1} a'_j\right) \\
&= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left[\left(\bigodot_{j=1}^{n} a'_j\right) \odot a'_{n+1}\right] \\
&= \left[\left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{j=1}^{n} a'_j\right)\right] \odot a'_{n+1} \\
&= \left[\left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+n} a_i\right)\right] \odot a_{m+(n+1)} \\
&= \left(\bigodot_{i=1}^{m+n} a_i\right) \odot a_{m+(n+1)} \\
&= \left(\bigodot_{i=1}^{m+n} a_i\right) \odot a_{(m+n)+1} \\
&= \bigodot_{i=1}^{(m+n)+1} a_i \\
&= \bigodot_{i=1}^{m+(n+1)} a_i
\end{aligned}
$$

by applying (5.446), (5.388), the associativity of $\odot$, (5.446) together with (5.445), the induction assumption (5.448) based on the evident fact that the restriction $s \upharpoonright \{1, \ldots, m+n\}$ is the sequence $(a_i \,|\, i \in \{1, \ldots, m+n\})$ and thus an element of $X^{\{1,\ldots,m+n\}}$, then the associativity of $+_{\mathbb{N}}$, again (5.388), and finally again the associativity of $+_{\mathbb{N}}$. This proves the implication in (5.449), and since s is arbitrary, we may therefore conclude that the universal sentence (5.449) is true. As n is also arbitrary, we may then further conclude that the induction step holds, so that the proof by mathematical induction is complete. Moreover, X, $\odot$ and m were initially arbitrary sets, so that the proposed universal sentence follows to true. $\square$

Theorem 5.118 (Generalized Associative Law for semigroups). *For any semigroup $(X, \odot)$ such that X contains the neutral element with respect to $\odot$, for any $n \in \mathbb{N}_+$, for any sequence $s = (a_i \,|\, i \in \{1, \ldots, n\})$ in X and for any $m \in \mathbb{N}$ with $m \leq n$, it is true that*

$$\bigodot_{i=1}^{n} a_i = \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{n} a_i\right) \tag{5.450}$$

$$= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{j=1}^{n-m} a_{m+j}\right) \tag{5.451}$$

Proof. We let X, $\odot$, m, n and s be arbitrary sets such that $(X, \odot)$ is a semigroup where X contains the neutral element e with respect to $\odot$, such that m and n are natural number satisfying $m \leq n$, and such that $s = (a_i \,|\, i \in \{1, \ldots, n\})$ is a sequence in X. Here, the assumed inequality implies with Corollary 5.88 that there exists a unique natural number N satisfying $m + N = n$. With this equation and Lemma 5.117 we then obtain

$$\begin{aligned}\bigodot_{i=1}^{n} a_i &= \bigodot_{i=1}^{m+N} a_i \\ &= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+N} a_i\right) \\ &= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{n} a_i\right)\end{aligned}$$

which equations yield the desired equations (5.450). Moreover, the inequality $m \leq n$ and the equation $m + N = n$ imply $N = n - m$ by definition of a difference, so that Lemma 5.117 gives now in connection with (5.446)

$$\begin{aligned}\bigodot_{i=1}^{n} a_i = \bigodot_{i=1}^{m+N} a_i &= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{i=m+1}^{m+N} a_i\right) \\ &= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{j=1}^{N} a_{m+j}\right) \\ &= \left(\bigodot_{i=1}^{m} a_i\right) \odot \left(\bigodot_{j=1}^{n-m} a_{m+j}\right),\end{aligned}$$

so that (5.451) also holds. Since X, $\odot$, m, n and s were initially arbitrary sets, we may therefore infer from this the truth of the stated theorem. □

Corollary 5.119. *It is true for any ordered elementary domain* $(X, +, \cdot, <)$ *that*

$$\forall m, n, s\,([m, n \in \mathbb{N} \,\wedge\, s : \{1, \ldots, n\} \to X] \Rightarrow [m \leq_{\mathbb{N}} n \Rightarrow \sum_{i=1}^{m} s_i \leq \sum_{i=1}^{n} s_i]). \tag{5.452}$$

Proof. We let X, $+$, $\cdot$, $<$, m, n and s be arbitrary sets such that $(X, +, \cdot, <)$ is an ordered elementary domain, such that m and n are natural numbers, and such that s is a function from $\{1, \ldots, n\}$ to X; thus, we may write s in sequence notation as $(s_i \,|\, i \in \{1, \ldots, n\})$. Next, we assume $m \leq_{\mathbb{N}} n$ to be true, so that the Generalized Associative Law for semigroups yields the equation

$$\sum_{i=1}^{n} s_i = \left(\sum_{i=1}^{m} s_i\right) + \left(\sum_{i=m+1}^{n} s_i\right). \tag{5.453}$$

Let us now observe in light of Proposition 5.59b), Theorem 5.62 and the definition of an induced reflexive partial ordering that $0 \leq \sum_{i=m+1}^{n} s_i$ holds. An application of the Monotony Law for $+$ and $\leq$ gives us then

$$0 + \sum_{i=1}^{m} s_i \;\leq\; \sum_{i=m+1}^{n} s_i + \sum_{i=1}^{m} s_i,$$

which inequality we may write also as

$$\sum_{i=1}^{m} s_i \;\leq\; \left(\sum_{i=1}^{m} s_i\right) + \left(\sum_{i=m+1}^{n} s_i\right)$$

by applying the commutativity of the addition on X and the fact that 0 is the zero element of X. Combining the preceding inequality with the previously established equation (5.453) via substitution yields then the desired inequality $\sum_{i=1}^{m} s_i \leq \sum_{i=1}^{n} s_i$. Since X, $+$, $\cdot$, $<$, m, n and s were initially arbitrary, we may therefore conclude that the corollary holds. □

Proposition 5.120. *For any ordered elementary domain* $(X, +, \cdot, <)$*, it is true that*

$$\begin{aligned}&\forall n\,(n \in \mathbb{N}_+ \Rightarrow \forall s, j, k\,([s : \{1, \ldots, n\} \to X \,\wedge\, j, k \in \{1, \ldots, n\}]\\ &\quad \Rightarrow [j \neq k \Rightarrow s_j + s_k \leq \sum_{i=1}^{n} s_i]))\end{aligned} \tag{5.454}$$

Proof. We let $(X, +, \cdot, <)$ be an arbitrary ordered elementary domain, and we prove the universal sentence with respect to n by mathematical induction. In the base case $n = 1$, we let s, j, k be arbitrary such that s is a 1-tuple in X and $j, k \in \{1\}$ (using the definition of an initial segment of $\mathbb{N}_+$). The latter implies $j = k = 1$ with (2.169), so that $j \neq k$ is false. This in turn implies the truth of the implication having that false inequality as the antecedent. Since s, j and k were arbitrary, we may therefore conclude that the base case holds. Regarding the induction step, we let $n \in \mathbb{N}_+$ be arbitrary, we make the induction assumption

$$\begin{aligned} &\forall s, j, k\,([s : \{1, \ldots, n\} \to X \ \wedge\ j, k \in \{1, \ldots, n\}] \\ &\quad \Rightarrow [j \neq k \Rightarrow s_j + s_k \leq \sum_{i=1}^{n} s_i]), \end{aligned} \tag{5.455}$$

and we show that

$$\begin{aligned} &\forall s, j, k\,([s : \{1, \ldots, n+1\} \to X \ \wedge\ j, k \in \{1, \ldots, n+1\}] \\ &\quad \Rightarrow [j \neq k \Rightarrow s_j + s_k \leq \sum_{i=1}^{n+1} s_i]), \end{aligned} \tag{5.456}$$

follows to be true as well. For this purpose, we let s be an arbitrary $(n+1)$-tuple in X and j, k arbitrary elements of the initial segment of $\mathbb{N}_+$ up to $n + 1$. Furthermore, we assume $j \neq k$ to be true. Let us observe here that $n \in \mathbb{N}_+$ implies $1 \leq_{\mathbb{N}} n$ with (4.278), so that the disjunction $1 <_{\mathbb{N}} n \vee 1 = n$ holds in view of the Characterization of induced irreflexive partial orderings. We prove the desired inequality $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$ by two cases, based on this disjunction.

In the first case $1 <_{\mathbb{N}} n$, we note that $n \in \mathbb{N}_+$ implies $i, j \in \{1, \ldots, n\} \cup \{n + 1\}$ with (4.241), so that the disjunctions

$$\begin{aligned} j \in \{1, \ldots, n\} \ \vee\ j \in \{n + 1\}, \\ k \in \{1, \ldots, n\} \ \vee\ k \in \{n + 1\} \end{aligned}$$

follow to be true by definition of the union of two sets. We may prove here by contradiction that $j \in \{n+1\}$ implies $k \notin \{n+1\}$. Assuming $j \in \{n+1\}$ (so that $j = n+1$) and the negation of $k \notin \{n+1\}$ to be true, we find with the Double Negation Law $k \in \{n + 1\}$ (so that $k = n + 1$); consequently, $j = k$, in contradiction to the previous assumption that $j \neq k$ is true. We now use these disjunctions to prove the inequality $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$ by two cases and by two subcases within the first case.

In the first case $j \in \{1, \ldots, n\}$ and the first subcase $k \in \{1, \ldots, n\}$, we evidently have that the restriction of s to $\{1, \ldots, n\}$ is an n-tuple in X_+^0.

Consequently, we obtain the inequality $s_j + s_k \leq \sum_{i=1}^{n} s_i$ with the induction assumption (5.455). Since the term s_{n+1} of the $(n+1)$-tuple s is clearly an element of the codomain X, the inequality $0 \leq s_{n+1}$ holds according to (5.276). Due to the Additivity of $\leq$-inequalities, we may combine the preceding two inequalities to

$$s_j + s_k + 0 \ \leq \ \sum_{i=1}^{n} s_i + s_{n+1},$$

(omitting brackets in view of the associativity of the addition) which yields the desired inequality with the property of a neutral element and (5.417). The second subcase $k \in \{n+1\}$ evidently implies $k = n+1$, so that $s_k = s_{n+1}$. Let us now consider the two further cases $j = n$ and $j \neq n$. If $j = n$ holds, we observe that $n \in \mathbb{N}_+$ implies $1 \in \{1, \ldots, n\}$ with (4.248). Furthermore, the previous case assumption $1 <_{\mathbb{N}} n$ implies $n \neq 1$ with the Characterization of comparability with respect to the linear ordering $<_{\mathbb{N}}$, so that substitution gives $j \neq 1$. These findings and the case assumption $j \in \{1, \ldots, n\}$ imply $s_1 + s_j \leq \sum_{i=1}^{n} s_i$ with the induction assumption. Clearly, the term s_1 is an element of the codomain X, so that $0 \leq s_1$ holds. Recalling now the truth of $s_k = s_{n+1}$, we may apply the Additivity of $\leq$-inequalities and the Monotony Law for $+$ and $\leq$ to the preceding inequality to obtain

$$s_1 + s_j + s_k + 0 \leq \sum_{i=1}^{n} s_i + s_{n+1} + s_1,$$

which inequality we can simplify by means of the Cancellation Law for $+$ (and the commutativity of the addition) to $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$, as desired. If $j \neq n$, then we observe that $n \in \mathbb{N}_+$ implies $n \in \{1, \ldots, n\}$ with (4.247), so that the induction assumption yields $s_n + s_j \leq \sum_{i=1}^{n} s_i$. Using now facts $0 \leq s_n$ and $s_k = s_{n+1}$, we evidently obtain from that inequality

$$s_n + s_j + s_k + 0 \leq \sum_{i=1}^{n} s_i + s_{n+1} + s_n$$

and therefore the desired inequality $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$.

In the second case $j \in \{n+1\}$, which implies $k \notin \{n+1\}$ as shown before and therefore $k \in \{1, \ldots, n\}$, we may evidently proceed in analogy to the preceding second subcase $k \in \{n+1\}$ of the first case $j \in \{1, \ldots, n\}$, if we consider the two possibilities $k = n$ and $k \neq n$. Here $j \in \{n+1\}$ evidently implies $j = n+1$, so that $s_j = s_{n+1}$. Let us now consider the two further cases $k = n$ and $k \neq n$. If $k = n$ holds, we recall the previous findings $1 \in \{1, \ldots, n\}$ and $n \neq 1$, so that $k \neq 1$. These findings and the subcase assumption $k \in \{1,\ldots,n\}$ imply $s_1 + s_k \leq \sum_{i=1}^n s_i$ with the induction assumption. Recalling the facts $0 \leq s_1$ and $s_j = s_{n+1}$, we obtain

$$s_1 + s_k + s_j + 0 \leq \sum_{i=1}^{n} s_i + s_{n+1} + s_1,$$

and therefore $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$, as desired. If $k \neq n$, then we recall $n \in \{1,\ldots,n\}$, so that the induction assumption yields $s_n + s_k \leq \sum_{i=1}^n s_i$. Using now facts $0 \leq s_n$ and $s_j = s_{n+1}$, we evidently obtain from that inequality

$$s_n + s_k + s_j + 0 \leq \sum_{i=1}^{n} s_i + s_{n+1} + s_n$$

and therefore the desired inequality $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$.

We now switch to the other case $1 = n$, which evidently gives $n + 1 = 2$ and therefore $\{1,\ldots,n+1\} = \{1,2\}$ with (4.242). By definition of a pair, the previous assumption $j,k \in \{1,\ldots,n+1\}$ therefore means that the disjunctions $j = 1 \vee j = 2$ and $k = 1 \vee k = 2$ are true. We use the first one to prove the inequality $s_j + s_k \leq \sum_{i=1}^2 s_i$ by cases. On the one hand, $j = 1$ evidently implies with the previous assumption $j \neq k$ that $k = 2$ holds. We then obtain

$$s_j + s_k = s_1 + s_2 = \sum_{i=1}^{2} s_i \quad \left[\leq \sum_{i=1}^{2} s_i\right]$$

applying substitutions, (5.413) and the reflexivity of the total ordering $\leq$; thus, $s_j + s_k \leq \sum_{i=1}^2 s_i$, as desired. On the other hand, $j = 2$ clearly implies $k = 1$ and therefore

$$s_j + s_k = s_2 + s_1 = s_1 + s_2 = \sum_{i=1}^{2} s_i \quad \left[\leq \sum_{i=1}^{2} s_i\right],$$

resulting in the same inequality again. Another substitution based on the equation $n + 1 = 2$ gives us then $s_j + s_k \leq \sum_{i=1}^{n+1} s_i$, completing the proof by cases. Since n was arbitrary, we may infer from the previous findings the truth of the induction step, and thus the truth of the universal sentence (5.454). As $(X,+,\cdot,<)$ was initially also arbitrary, the proposition finally follows to be true. $\square$

Proposition 5.121. *For any ordered integral domain* $(X,+,\cdot,-,<)$ *an* n*-fold sum is zero iff all terms of the* n*-tuple are zero, that is,*

$$\forall n\,(n\in\mathbb{N}\Rightarrow\forall s\,(s\in X^{\{1,\ldots,n\}}$$
$$\Rightarrow\left[\sum_{i=1}^{n}s_i=0_X\Leftrightarrow\forall i\,(i\in\{1,\ldots,n\}\Rightarrow s_i=0_X)\right])). \tag{5.457}$$

Proof. Letting $(X,+,\cdot,<)$ be an arbitrary ordered elementary domain, we apply a proof by mathematical induction. Regarding the base case ($n=0$), we let $s\in X^{\{1,\ldots,n\}}$ be arbitrary, so that $s=\emptyset$ due to (4.239) and (3.120). Let us observe on the one hand that $\sum_{i=1}^{0}s_i=0_X$ holds according to (5.409). On the other hand, letting i be arbitrary, we see that $i\in\{1,\ldots,0\}$ $[=\emptyset]$ is false, so that the implication $i\in\{1,\ldots,n\}\Rightarrow s_i=0_X$ is true. As i is arbitrary, we conclude that the universal sentence $\forall i\,(i\in\{1,\ldots,n\}\Rightarrow s_i=0_X)$ holds, too. Thus, the equivalence in (5.457) is true for $n=0$. Then, because s is arbitrary, we may infer from this finding the truth of the base case. Regarding the induction step, we let $n\in\mathbb{N}$ be arbitrary, make the induction assumption

$$\forall s\,(s\in X^{\{1,\ldots,n\}}\Rightarrow\left[\sum_{i=1}^{n}s_i=0_X\Leftrightarrow\forall i\,(i\in\{1,\ldots,n\}\Rightarrow s_i=0_X)\right]),$$

and show that

$$\forall s\,(s\in X^{\{1,\ldots,n+1\}}\Rightarrow\left[\sum_{i=1}^{n+1}s_i=0_X\Leftrightarrow\forall i\,(i\in\{1,\ldots,n+1\}\Rightarrow s_i=0_X)\right]) \tag{5.458}$$

follows to be true. Letting $s\in X^{\{1,\ldots,n+1\}}$ be arbitrary, we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $\sum_{i=1}^{n+1}s_i=0_X$ to be true and demonstrating the truth of

$$\forall i\,(i\in\{1,\ldots,n+1\}\Rightarrow s_i=0_X). \tag{5.459}$$

Due to the assumed equation, we thus have

$$\sum_{i=1}^{n}s_i+s_{n+1}=0_X. \tag{5.460}$$

in view of (5.417). We may now apply the Law of Contraposition with (5.278) to infer from that equation the truth of $\sum_{i=1}^{n}s_i=0_X$. Rewriting (5.460) by means of the commutativity of the addition as $s_{n+1}+\sum_{i=1}^{n}s_i=$

0_X, we obtain with the same arguments also $s_{n+1} = 0_X$. Here, the former gives us with the induction assumption the true universal sentence

$$\forall i\,(i \in \{1,\ldots,n\} \Rightarrow s_i = 0_X). \tag{5.461}$$

We are now in a position to prove the universal sentence (5.459). To do this, we let $i \in \{1,\ldots,n+1\}$ be arbitrary, so that

$$i \in \{1,\ldots,n\} \cup \{n+1\} \tag{5.462}$$

holds by virtue of (4.241). By definition of the union of two sets, this means that the disjunction

$$i \in \{1,\ldots,n\} \;\vee\; i = n+1 \tag{5.463}$$

is true (using also (2.169)). We now use this true disjunction to prove $s_i = 0_X$ by cases. The first case $i \in \{1,\ldots,n\}$ immediately gives the desired equation with (5.461). The second case $i = n+1$ yields $s_i = 0_X$ via substitution into the previously established equation $s_{n+1} = 0_X$. Thus, $s_i = 0_X$ holds in any case, and since i was arbitrary, we therefore conclude that the universal sentence (5.459) is indeed true. This finding completes the proof of the first part of the equivalence in (5.458) is complete.

To establish the second part ('$\Leftarrow$'), we assume now (5.459) to be true, and we show that $\sum_{i=1}^{n+1} s_i = 0_X$ holds, too. For this purpose, we prove (5.461), letting i be arbitrary and assuming $i \in \{1,\ldots,n\}$ to hold. Then, the disjunction (5.463) is also true, which evidently implies (5.462) and then $i \in \{1,\ldots,n+1\}$. This in turn implies $s_i = 0_X$ with the assumption (5.459). As i was arbitrary, we therefore conclude that (5.461) is true, and this universal sentence gives us now the true equation $\sum_{i=1}^{n} s_i = 0_X$ with the induction assumption. Since the evident fact $n+1 \in \{1,\ldots,n+1\}$ implies also $s_{n+1} = 0_X$ with the assumption (5.459), we evidently obtain the true equation (5.460), which finding completes the proof of the equivalence.

Since s was arbitrary, we may therefore conclude that the universal sentence (5.458) holds. Then, as n was also arbitrary, we may further conclude that the induction step is true. Thus, the proof of (5.121) by mathematical induction is complete. Here, $(X, +, \cdot, <)$ was initially also arbitrary, so that the proposition follows to be true. □

Exercise 5.48. Show for any set X, for any addition $+_X$ such that the zero element of X with respect to $+_X$ exists, and for any element c of X that an n-fold sum equals c if one term of the n-tuple equals c and the other terms are zero, i.e. that

$$\forall n\,(n \in \mathbb{N} \Rightarrow \forall s\,(s \in X^{\{1,\ldots,n\}} \Rightarrow [\exists j\,(j \in \{1,\ldots,n\} \wedge s_j = c$$
$$\wedge\ \forall k\,(k \in \{1,\ldots,n\} \setminus \{j\} \Rightarrow s_k = 0)) \Rightarrow \sum_{i=1}^{n} s_i = c]). \tag{5.464}$$

Proof. To do!

□

Notation 5.18. Equations (5.450) – (5.450) show that the value $\bigodot_{i=1}^{n} a_i$ of the n-fold repeated binary operation is independent of the 'order' (indicated by the brackets) in which the terms of the sequences are processed. We therefore write

$$\bigodot_{i=1}^{n} a_i = a_1 \odot \cdots \odot a_n. \tag{5.465}$$

To give a first example, we recall the n-fold join, based on a lattice $(X, \sqcup, \sqcap, \leq)$ with the semigroup $(X, \sqcup)$ (as established in Proposition 5.33).

Notation 5.19. For any lattice $(X, \sqcup, \sqcap, <)$ such that X contains the neutral element with respect to $\sqcup$, for any $n \in \mathbb{N}$ and for any sequence $(a_i \,|\, i \in \{1, \ldots, n\})$ in X, we also write

$$\sqcup_{i=1}^{n} a_i = a_1 \sqcup \cdots \sqcup a_n = \sup\{a_1, \ldots, a_n\} \tag{5.466}$$

and call this the supremum of $a_1, \ldots, a_n$. We then also say that the n-fold join $\sqcup_{i=1}^{n}$ is the *n-ary join* on X.

Notation 5.20. For any semigroup $(X, +)$ such that X contains the neutral element for the addition $+$, any $n \in \mathbb{N}$ and any sequence $(a_i \,|\, i \in \{1, \ldots, n\})$ in X, we also write

$$\sum_{i=1}^{n} a_i = a_1 + \cdots + a_n \tag{5.467}$$

(read as "the sum as i goes from 1 to n of a_i") and call this the *sum* of $a_1, \ldots, a_n$. We then also say that the n-fold addition $\sum_{i=1}^{n}$ is the *n-ary addition* on X.

In case of $a_i = a$ for all $i \in \{1, \ldots, n\}$ (with $n \in \mathbb{N}$) we also write

$$na \tag{5.468}$$

instead of $\sum_{i=1}^{n} a_i$, which we call a *multiple* of a; here, we call n the *multiplier*.

Notation 5.21. For any semigroup $(X, \cdot)$ such that X contains the neutral element for the multiplication $\cdot$, for any $n \in \mathbb{N}$ and for any sequence $(a_i \mid i \in \{1, \ldots, n\})$ in X, we also write

$$\prod_{i=1}^{n} a_i = a_1 \cdot \ldots \cdot a_n \tag{5.469}$$

(read as "the product as i goes from 1 to n of a_i") and call this the *product* of $a_1, \ldots, a_n$. We then also say that the n-fold multiplication $\prod_{i=1}^{n}$ is the *n-ary multiplication* on X.

In case of $a_i = a$ for all $i \in \{1, \ldots, n\}$ (with $n \in \mathbb{N}$) we also write

$$a^n \tag{5.470}$$

instead of $\prod_{i=1}^{n} a_i$ and speak of the *n-th power* of a; here, we call a the *base* and n the *exponent* (semigroup). We call in particular a^2 the *square* of a.

Let us apply the preceding notations now to the 1-, 2-, 3-, and $(n+1)$-fold iterated additions and multiplications established in Corollary 5.109.

Corollary 5.122. *The following sentences are true.*

a) *For any semigroup $(X, +)$ such that X contains the zero element 0_X and for any $a \in X$, it is true that*

$$0a = 0_X, \tag{5.471}$$

$$1a = a, \tag{5.472}$$

$$2a = a + a, \tag{5.473}$$

$$3a = a + a + a, \tag{5.474}$$

$$(n+1)a = na + a \quad \text{for any } n \in \mathbb{N}. \tag{5.475}$$

b) *For any semigroup $(X, \cdot)$ such that X contains the unity element 1_X and for any $a \in X$, it is true that*

$$a^0 = 1_X, \tag{5.476}$$

$$a^1 = a, \tag{5.477}$$

$$a^2 = a \cdot a, \tag{5.478}$$

$$a^3 = a \cdot a \cdot a, \tag{5.479}$$

$$a^{n+1} = a^n \cdot a \quad \text{for any } n \in \mathbb{N}. \tag{5.480}$$

Proposition 5.123. *It is true for any semigroup $(X, +)$ with zero element 0_X that*

$$\forall a, b\,([a, b \in X \,\wedge\, a + b = b + a] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow a + nb = nb + a)). \quad (5.481)$$

Proof. We let X, $+$, a and b be arbitrary such that $(X, +)$ is a semigroup with zero element 0_X, such that a and b are elements of X, and such that $a + b = b + a$ holds. We now prove the universal sentence with respect to n by mathematical induction. In the base case ($n = 0$), we obtain the equations

$$\begin{aligned} a + nb &= a + 0b \\ &= a + 0^X \\ &= a \\ &= 0_X + a \\ &= 0b + a \\ &= nb + a \end{aligned}$$

by applying substitution, (5.471), the definition of the zero element, again the definition of the zero element, again (5.471), and finally again substitution. In the induction step, we let $n \in \mathbb{N}$ be arbitrary, make the induction assumption $a + nb = nb + a$, and observe the truth of the equations

$$\begin{aligned} a + (n+1)b &= a + (nb + b) \\ &= (a + nb) + b \\ &= (nb + a) + b \\ &= nb + (a + b) \\ &= nb + (b + a) \\ &= (nb + b) + a \\ &= (n+1)b + a \end{aligned}$$

in light of (5.475), the associativity of $+$, the induction assumption, the associativity of $+$, the assumption $a + b = b + a$, the associativity of $+$, and (5.475). Since n was arbitrary, we may therefore conclude that the induction step holds, so that the proof by mathematical induction is complete. As X, $+$, a and b were also arbitrary, we may then further conclude that the proposed universal sentence is true. □

Exercise 5.49. Prove for any semigroup $(X, \cdot)$ with unity element 1_X that

$$\forall a, b\,([a, b \in X \,\wedge\, a \cdot b = b \cdot a] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow a \cdot b^n = b^n \cdot a)). \quad (5.482)$$

(Hint: Proceed similarly as in the proof of Proposition 5.481.)

Proposition 5.124. *It is true for any semigroup $(X,+)$ with zero element 0_X that*

$$\forall a,b\,([a,b\in X\wedge a+b=b+a]\Rightarrow \forall n\,(n\in\mathbb{N}\Rightarrow n(a+b)=na+nb)). \quad (5.483)$$

Proof. We let X, $+$, a and b be arbitrary such that $(X,+)$ is a semigroup with zero element 0_X, such that a and b are elements of X, and such that $a+b=b+a$ holds. We now prove the universal sentence with respect to n by mathematical induction. In the base case ($n=0$), we have

$$n(a+b)^n = 0(a+b) = 0_X = 0_X + 0_X = 0a + 0b = na + nb$$

by applying substitution, (5.471), the definition of the identity element, again (5.471), and then two more substitutions. To prove the induction step, we let $n\in\mathbb{N}$ be arbitrary, make the induction assumption $n(a+b)=na+nb$, and derive the equations

$$\begin{aligned}
(n+1)(a+b) &= n(a+b)+(a+b)\\
&= (na+nb)+(a+b)\\
&= ((na+nb)+a)+b\\
&= (na+(nb+a))+b\\
&= (na+(a+nb))+b\\
&= ((na+a)+nb)+b\\
&= ((n+1)a+nb)+b\\
&= (n+1)a+(nb+b)\\
&= (n+1)a+(n+1)b
\end{aligned}$$

by means of (5.475), the induction assumption, the associativity of $+$, again the associativity of $+$, (5.481), again the associativity of $+$, again (5.475), again the associativity of $+$, and finally again (5.475). Since n is arbitrary, we may infer from the resulting equation $(n+1)(a+b)=(n+1)a+(n+1)b$ the truth of the induction step. As X, $+$, a and b were also arbitrary, we may then further conclude that the proposed universal sentence is true. □

Exercise 5.50. Show for any semigroup $(X,\cdot)$ with unity element 1_X that multiplying two powers with commuting bases and identical exponents corresponds to multiplying the bases, that is,

$$\forall a,b\,([a,b\in X\ \wedge\ a\cdot b=b\cdot a]\Rightarrow \forall n\,(n\in\mathbb{N}\Rightarrow (a\cdot b)^n=a^n\cdot b^n)). \quad (5.484)$$

(Hint: Apply a similar proof as for Proposition 5.124.)

Proposition 5.125. *It is true for any semigroup* $(X, +)$ *with zero element* 0_X *that any multiple of the zero element equals that element, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow n0_X = 0_X). \tag{5.485}$$

Proof. We let X and $+$ be arbitrary sets and assume $(X, +)$ to be a semigroup such that the zero element of X exists. In the base case ($n = 0$), we have

$$n0_X = 00_X = 0_X$$

because of (5.471), as desired. Concerning the induction step, we take an arbitrary natural number n and make the induction assumption $n0_X = 0_X$. Then, we obtain

$$(n+1)0_X = n0_X + 0_X = 0_X + 0_X = 0_X$$

with (5.475), the induction assumption and the definition of the zero element. Since n is arbitrary, we may therefore conclude that the induction step holds (besides the base case), so that the proof of (5.485) is complete. As X and $+$ were also arbitrary, the proposition follows then to be true. □

Exercise 5.51. It is true for any semigroup $(X, \cdot)$ with unity element 1_X that any power of the unity element equals that element, i.e.

$$\forall n\,(n \in \mathbb{N} \Rightarrow [1_X]^n = 1_X). \tag{5.486}$$

(Hint: The proof is similar to that of Proposition 5.125.)

Theorem 5.126 (Addition & Multiplication Rules for multiples & powers in a semigroup). *The following laws hold, respectively, for any semigroup* $(X, +_X)$ *with zero element* 0_X *and for any semigroup* $(X, \cdot_X)$ *with identity element* 1_X*.*

a) **Addition Rule for multiples in a semigroup***:*

$$\forall a, m, n\,([a \in X \wedge m, n \in \mathbb{N}] \Rightarrow (m+n)a = ma +_X na). \tag{5.487}$$

b) **Multiplication Rule for multiples in a semigroup***:*

$$\forall a, m, n\,([a \in X \wedge m, n \in \mathbb{N}] \Rightarrow (m \cdot n)a = n[ma]). \tag{5.488}$$

c) **Addition Rule for powers in a semigroup***:*

$$\forall a, m, n\,([a \in X \wedge m, n \in \mathbb{N}] \Rightarrow a^{m+n} = a^m \cdot_X a^n). \tag{5.489}$$

d) **Multiplication Rule for powers in a semigroup***:*

$$\forall a, m, n\,([a \in X \,\wedge\, m, n \in \mathbb{N}] \Rightarrow a^{m \cdot n} = [a^m]^n). \tag{5.490}$$

Proof. We let X and $\cdot_X$ be arbitrary and $(X, +_X)$ to be a semigroup for which the zero element 0_X exists.

Concerning a), we take an arbitrary constant a and prove

$$\forall m\, \forall n\,([(a \in X \,\wedge\, m \in \mathbb{N}) \,\wedge\, n \in \mathbb{N}] \Rightarrow (m+n)a = ma +_X na), \tag{5.491}$$

which sentence is equivalent to

$$\forall m\,([a \in X \,\wedge\, m \in \mathbb{N}] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow (m+n)a = ma +_X na)), \tag{5.492}$$

because of (1.90). Letting here m also be arbitrary and assuming $a \in X$ as well as $m \in \mathbb{N}$ to be both true, we can now apply a proof by mathematical induction with respect to n. In the base case ($n = 0$), we observe the truth of the equations

$$(m+n)a = (m+0)a = ma = ma +_X 0_X = ma +_X 0a = ma +_X na$$

in light of the equation $n = 0$, the definition of the zero element of $\mathbb{N}$, the definition of the zero element 0_X and (5.471). Thus, the resulting equation $(m+n)a = ma +_X na$ proves the base case. In the induction step, we take an arbitrary natural number n, we make the induction assumption $(m+n)a = ma +_X na$, and we derive the equations

$$\begin{aligned}(m+[n+1])a &= ([m+n]+1)a \\ &= (m+n)a +_X a \\ &= (ma +_X na) +_X a \\ &= ma +_X (na +_X a) \\ &= ma +_X (n+1)a\end{aligned}$$

by using the Associative Law for the addition on $\mathbb{N}$, (5.472), the induction assumption, the associativity of $+_X$, and again (5.472). Since n is arbitrary, the resulting equation $(m+[n+1])a = ma +_X (n+1)a$ evidently proves the induction step, completing the proof by mathematical induction. As m was also arbitrary, we may further conclude that (5.492) and thus the equivalent universal sentence (5.491) hold. Because a was initially arbitrary, the universal sentence (5.487) follows then to be true.

Concerning b), we let a be arbitrary, so that we are required to prove

$$\forall m\, \forall n\,([(a \in X \,\wedge\, m \in \mathbb{N}) \,\wedge\, n \in \mathbb{N}] \Rightarrow (m \cdot n)a = n[ma]), \tag{5.493}$$

which we may write equivalently as

$$\forall m\,([a \in X \,\wedge\, m \in \mathbb{N}] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow (m \cdot n)a = n[ma])) \tag{5.494}$$

by utilizing (1.90). Next, we let m be arbitrary and assume $a \in X$ and $m \in \mathbb{N}$ to be both true, and we prove the universal sentence with respect to n by mathematical induction. The base case ($n = 0$) holds because we obtain the equations

$$(m \cdot n)a = (m \cdot 0)a = 0a = 0 = 0[ma] = n[ma]$$

by applying substitution based on $n = 0$, then the Cancellation Law for 0, (5.471), again (5.471), and finally again substitution based on $n = 0$. Regarding the induction step, we let $n \in \mathbb{N}$ be arbitrary, make the induction assumption $(m \cdot n)a = n[ma]$, and observe the truth of the equations

$$\begin{aligned}
[m \cdot (n+1)]a &= (m \cdot n + m \cdot 1)a \\
&= (m \cdot n)a +_X (m \cdot 1)a \\
&= n[ma] +_X ma \\
&= n[ma] +_X 1[ma] \\
&= (n+1)[ma]
\end{aligned}$$

in view of the distributivity of $\cdot_{\mathbb{N}}$ over $+_{\mathbb{N}}$, the previously established Addition Rule for multiples, the induction assumption as well as the definition of a neutral element, (5.472), and considering the Addition Rule for multiples once again. As n is arbitrary, we may therefore conclude that the induction step holds, so that the proof by mathematical induction is complete. Since m is also arbitrary, we may now further conclude that the universal sentence (5.494) is true. Thus, the equivalent sentence (5.493) also holds, and because a was also arbitrary, we may infer from this finding the truth of b).

Since X and $+_X$ were initially arbitrary, Part a) and Part b) of the stated theorem follow to be true. □

Exercise 5.52. Establish the Addition Rule and the Multiplication Rule for powers.

(Hint: Proceed in analogy to the proofs of the Addition Rule and the Multiplication Rule for multiples.)

Proposition 5.127. *For any ordered elementary domain $(X, +, \cdot, <)$, it is true that any power of an element $a \in X$ is different from the zero element if a is different from the zero element, i.e.*

$$\forall a\,([a \in X \,\wedge\, a \neq 0_X] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow a^n \neq 0_X)). \tag{5.495}$$

Proof. We let X, $+$, $\cdot$, $<$ and a be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain and such that the conjunction of $a \in X$ and $a \neq 0_X$ holds. Next, we apply a proof by mathematical induction, observing first that the base case ($n = 0$) yields

$$a^n = a^0 = 1_X \ (\neq 0_X),$$

where we applied substitution, then (5.476) and Theorem 5.68, so that we obtain $a^n = 0_X$ as desired. Regarding the induction step, we take an arbitrary $n \in \mathbb{N}$, assume $a^n \neq 0_X$, and verify $a^{n+1} \neq 0_X$. Since $a^{n+1} = a^n \cdot a$ is true according to (5.480), where $a^n \neq 0_X$ and $a \neq 0_X$ hold because of the previously made assumptions, it follows with the Criterion for zero-divisor freeness in particular that $a^n \cdot a \neq 0_X$ is true, so that substitution based on the preceding equation yields the desired $a^{n+1} \neq 0_X$. As n is arbitrary, we may therefore conclude that the induction step also holds, which finding completes the proof of the universal sentence with respect to n in (5.495). Since X, $+$, $\cdot$, $<$ and a were initially arbitrary, we may further conclude that the proposition holds, as claimed. □

Corollary 5.128. *It is true for the ordered elementary domain* $(\mathbb{N}, +, \cdot, <)$ *that any power of a natural number k is different from zero if k is different from zero, i.e.*

$$\forall k\,([k \in \mathbb{N} \wedge k \neq 0] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow k^n \neq 0)). \tag{5.496}$$

We now generalize the Distributive Law from binary operations to n-fold binary operations, which task we prepare by means of the following sentence.

Proposition 5.129. *For any set X, any multiplication $\cdot_X$ (on X), any element $c \in X$, any $n \in \mathbb{N}$ and any sequence $s = (a_i \,|\, i \in \{1, \ldots, n\})$ in X, it is true that there exists a unique sequence $t = (b_i \,|\, i \in \{1, \ldots, n\})$ such that every term b_i is the product of c and the term a_i, i.e. such that*

$$\forall i\,(i \in \{1, \ldots, n\} \Rightarrow b_i = c \cdot_X a_i) \tag{5.497}$$

holds. Furthermore, t is a sequence in X.

Proof. Letting X, $\cdot_X$, c, n and s be arbitrary, we assume that $\cdot_X$ is a binary (multiplication) operation on X, that $c \in X$ and $n \in \mathbb{N}$ are true, and moreover that $s = (a_i \,|\, i \in \{1, \ldots, n\})$ is a sequence in X. We now prove the universal sentence

$$\forall i\,(i \in \{1, \ldots, n\} \Rightarrow \exists! y\,(y = c \cdot_X a_i)), \tag{5.498}$$

letting i be arbitrary and assuming $i \in \{1, \ldots, n\}$ to be true. Since $\{1, \ldots, n\}$ is the domain of the sequence $s = (a_i \,|\, i \in \{1, \ldots, n\})$ in X, it follows with the Function Criterion that the term a_i is an element of X. As we assumed c to be an element of X as well, we find the product $c \cdot_X a_i$ to be an element of X, too. Then, the uniquely existential sentence in (5.498) follows to be true with Proposition 1.21, and because i is arbitrary, we may therefore conclude that the universal sentence (5.498) holds. According to Theorem 3.160, there then exists a unique function t with domain $\{1, \ldots, n\}$ such that $t(i) = c \cdot_X a_i$ holds for any $i \in \{1, \ldots, n\}$. Thus, we may write t as the sequence $t = (b_i \,|\, i \in \{1, \ldots, n\})$ whose terms evidently satisfy (5.497). In view of the already established fact that the term $[b_i =]\, c \cdot_X a_i$ is an element of X for any $i \in \{1, \ldots, n\}$, we see in light of the Function Criterion that t is a sequence in X. Since X, $\cdot_X$, c, n and s were initially arbitrary, we may infer from this the truth of the proposed universal sentence. □

Note 5.29. This proposition shows that a sequence $(a_i \,|\, i \in \{1, \ldots, n\})$ in X induces a sequence $(c \cdot a_i \,|\, i \in \{1, \ldots, n\})$ in X. Therefore, if X contains the neutral element with respect to an addition on X, we may form both $\sum_{i=1}^{n} a_i$ and $\sum_{i=1}^{n} (c \cdot a_i)$.

Theorem 5.130 (Generalized Distributive Law for semirings). *The following law holds for any semiring $(X, +, \cdot)$, such that X contains the zero element 0_X, and for any element c in X.*

$$\forall n (n \in \mathbb{N} \Rightarrow \forall s \,(s \in X^{\{1, \ldots, n\}} \Rightarrow c \cdot \sum_{i=1}^{n} a_i = \sum_{i=1}^{n} (c \cdot a_i))). \tag{5.499}$$

Proof. We let X, $+_X$, $\cdot_X$ and c be arbitrary, assume that the ordered triple $(X, +, \cdot)$ is a semiring such that X contains the zero element 0_X (i.e., the neutral element of X with respect to $+_X$), and we assume that $c \in X$ holds. Now we apply a proof by mathematical induction. Regarding the base case $(n = 0)$, we let s be the empty sequence, and we obtain the equations

$$c \cdot \sum_{i=1}^{n} a_i = c \cdot \sum_{i=1}^{0} a_i = c \cdot 0_X = 0_X = \sum_{i=1}^{0} (c \cdot a_i) = \sum_{i=1}^{n} (c \cdot a_i)$$

by applying substitution based on $n = 0$, (5.409), the Cancellation Law for 0_X, again (5.409), and finally again substitution based on $n = 0$. These equations then yield the desired equation in (5.499).

Regarding the induction step, we let $n \in \mathbb{N}$ be arbitrary, make the induction assumption

$$\forall s\,(s \in X^{\{1,\ldots,n\}} \Rightarrow c \cdot \sum_{i=1}^{n} a_i = \sum_{i=1}^{n}(c \cdot a_i)), \tag{5.500}$$

and show that this implies

$$\forall s\,(s \in X^{\{1,\ldots,n^+\}} \Rightarrow c \cdot \sum_{i=1}^{n^+} a_i = \sum_{i=1}^{n^+}(c \cdot a_i)). \tag{5.501}$$

For this purpose, we let s be an arbitrary set and assume that $s = (a_i \,|\, i \in \{1,\ldots,n^+\})$ is a sequence in X. We then obtain the equations

$$\begin{aligned} c \cdot \sum_{i=1}^{n^+} a_i &= c \cdot \left(\sum_{i=1}^{n} a_i + a_{n^+}\right) \\ &= \left(c \cdot \sum_{i=1}^{n} a_i\right) + (c \cdot a_{n^+}) \\ &= \sum_{i=1}^{n}(c \cdot a_i) + (c \cdot a_{n^+}) \\ &= \sum_{i=1}^{n^+}(c \cdot a_i) \end{aligned}$$

applying (5.388) to the sequence $(a_i \,|\, i \in \{1,\ldots,n^+\})$, the distributivity of $\cdot$ over $+$ (according to Property 3 of a semiring), the induction assumption, (5.388) based on the sequence $s \restriction \{1,\ldots,n\}$, and applying (5.388) now to the sequence $(c \cdot a_i \,|\, i \in \{1,\ldots,n^+\})$. Since s is arbitrary, we may therefore conclude that the universal sentence (5.501) is true, and as n was also arbitrary, we may further conclude that the induction step is true (besides the base case). Thus, the proof of (5.499) is complete, and because X, $+_X$, $\cdot_X$ and c were initially arbitrary, we may infer from this the truth of the stated theorem. □

5.6.2. Factorials

Proposition 5.131. *There exists a unique function f with domain $\mathbb{N}$ with*

$$\forall n\,(n \in \mathbb{N} \Rightarrow f(n) = \prod_{i=1}^{n} i) \tag{5.502}$$

holds, and this function is a sequence in $\mathbb{N}$.

Proof. We first apply Function definition by replacement and verify for this purpose

$$\forall n\,(n \in \mathbb{N} \Rightarrow \exists! y\,(y = \prod_{i=1}^{n} i)). \tag{5.503}$$

Letting $n \in \mathbb{N}$ be arbitrary, we may evidently use the semigroup $(\mathbb{N}, \cdot_{\mathbb{N}})$ and the sequence

$$(i \,|\, i \in \{1, \ldots, n\}) = \mathrm{id}_{\mathbb{N}} \upharpoonright \{1, \ldots, n\}$$

to form the natural number $\prod_{i=1}^{n} i$. Then, the uniquely existential sentence follows immediately to be true with (1.109). Since n is arbitrary, we may therefore conclude that the universal sentence (5.503) is true, so that there exists a unique function f with domain $\mathbb{N}$ such that (5.502) holds. Thus, we may write f as the sequence $(f_n)_{n \in \mathbb{N}}$. Furthermore, because $\prod_{i=1}^{n} i$ is an element of $\mathbb{N}$ for any $n \in \mathbb{N}$, we also see in light of the Function Criterion that f is a function/sequence from $\mathbb{N}$ to $\mathbb{N}$. □

Definition 5.25 (Factorial function, factorial). We call the function

$$f : \mathbb{N} \to \mathbb{N}, \quad n \mapsto f(n) = \prod_{i=1}^{n} i \tag{5.504}$$

the *factorial function*, and we call for any $n \in \mathbb{N}$ the corresponding function value $f(n)$ the *factorial* of n, which we symbolize by

$$n! \tag{5.505}$$

Theorem 5.132 (Recurrence Relation for factorials). *The following law applies to factorials.*

$$0! = 1 \,\wedge\, \forall n\,(n \in \mathbb{N}_+ \Rightarrow n! = (n-1)! \cdot n). \tag{5.506}$$

Proof. The first part of the conjunction results from the equations

$$0! = \prod_{i=1}^{0} i = 1, \tag{5.507}$$

using (5.504) and (5.410). Next, we apply a proof by mathematical induction to establish the second part of the proposed conjunction. Regarding the base case $(n = 1)$, we obtain the equations

$$n! \,=\, 1! \,=\, \prod_{i=1}^{1} i \,=\, 1 \,=\, 1 \cdot 1 \,=\, 0! \cdot 1 \,=\, (1-1)! \cdot 1 \,=\, (n-1)! \cdot n$$

by applying substitution, (5.504), (5.412), the definition of a neutral element, then the previously established (5.507), (5.345), and finally again substitution.

Regarding the induction step, we let $n \in \mathbb{N}_+$ be arbitrary, assume that $n! = (n-1)! \cdot n$ holds, and observe the truth of the equations

$$\begin{aligned}(n+1)! &= \prod_{i=1}^{n+1} i \\ &= \left(\prod_{i=1}^{n} i\right) \cdot (n+1) \\ &= \left(\prod_{i=1}^{(n+1)-1} i\right) \cdot (n+1) \\ &= ([n+1]-1)! \cdot (n+1)\end{aligned}$$

in light of (5.504), (5.418) and (5.344). Because n is arbitrary, we may therefore conclude that the induction step holds (which we proved here without using the induction assumption!). Thus, the proof of the universal sentence in (5.506) by mathematical induction is complete, so that the stated conjunction is indeed true. □

Exercise 5.53. Establish the following law for factorials.

$$\forall n\,(n \in \mathbb{N} \Rightarrow (n+1)! = n! \cdot (n+1)). \tag{5.508}$$

5.6.3. Series

Exercise 5.54. Show for any set X, any addition $+$ on X such that X contains the zero element 0_X and any sequence $f = (a_n)_{n \in \mathbb{N}_+}$ in X that there exists a unique sequence $s = (s_n)_{n \in \mathbb{N}_+}$ in X satisfying

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow s_n = \sum_{i=1}^{n} a_i). \tag{5.509}$$

(Hint: Apply Theorem 3.160 in connection with Proposition 5.106 and the restrictions $(a_i \,|\, i \in \{1, \ldots, n\}) = f \upharpoonright \{1, \ldots, n\}$ with $n \in \mathbb{N}_+$.)

Definition 5.26 ((Generated) series, partial sum). For any set X, any addition $+$ on X such that X contains the zero element 0_X and any sequence $f = (a_n)_{n \in \mathbb{N}_+}$ in X, we call the sequence

$$(s_n)_{n \in \mathbb{N}_+} = (\sum_{i=1}^{n} a_i)_{n \in \mathbb{N}_+} \tag{5.510}$$

the *series generated* by $(a_n)_{n\in\mathbb{N}_+}$, and we call for any $n \in \mathbb{N}_+$ the term

$$s_n = \sum_{i=1}^{n} a_i \tag{5.511}$$

the n-th *partial sum* (of the series).

Notation 5.22. For any partially ordered set $(Y, \leq_Y)$ and any sequence $f = (a_n)_{n\in\mathbb{N}_+}$ in Y generating an increasingly or decreasingly convergent series $s = (s_n)_{n\in\mathbb{N}_+} = (\sum_{i=1}^{n} a_i)_{n\in\mathbb{N}_+}$, we write for the limit of s

$$\sum_{i=1}^{\infty} a_i = \lim_{n\to\infty} s_n = \lim_{n\to\infty} \sum_{i=1}^{n} a_i. \tag{5.512}$$

Let us inspect a first example of a series and its tail characteristics.

Proposition 5.133. *For any set X and any addition $+_X$ on X such that X contains the zero element 0_X, as well as for any elements $\bar{a}, \bar{b} \in X$, it is true that*

a) the series $s = (s_n)_{n\in\mathbb{N}_+}$ generated by the sequence $f = (a_n)_{n\in\mathbb{N}_+}$ defined by (5.361) satisfies $s_1 = \bar{a}$ and

$$\forall n\,(n \in \mathbb{N}_+ \setminus \{1\} \Rightarrow s_n = \bar{a} +_X \bar{b}). \tag{5.513}$$

b) the 2nd tail of s is identical with the constant function on $\mathbb{N}_+$ with value $\bar{a} +_X \bar{b}$, i.e.

$$T_2^s = \mathbb{N}_+ \times \{\bar{a} +_X \bar{b}\} \quad [= g_{\bar{a}+_X\bar{b}}]. \tag{5.514}$$

Proof. We let X, $+_X$, $\bar{a}$ and $\bar{b}$ be arbitrary, assume that $+_X$ is an addition on X such that X contains the zero element 0_X, and assume moreover that $\bar{a}, \bar{b} \in X$ holds. Then, the sequence $f = (a_n)_{n\in\mathbb{N}_+}$ defined by (5.361) generates the series $s = (s_n)_{n\in\mathbb{N}_+}$ with $s_n = \sum_{i=1}^{n} a_i$ for any $n \in \mathbb{N}_+$. Concerning a), we first obtain with 5.411)

$$s_1 = \sum_{i=1}^{1} a_i = a_1 = \bar{a},$$

as claimed. Next, we observe in light of Exercise 4.10 that we may apply a proof by mathematical induction to establish (5.513). In the base case $(n = 2)$, we obtain with (5.413)

$$s_2 = \sum_{i=1}^{2} a_i = a_1 +_X a_2 = \bar{a} +_X \bar{b},$$

as desired. Letting now $n \in \mathbb{N}_+ \setminus \{1\}$ be arbitrary, we make the induction assumption $s_n = \bar{a} +_X \bar{b}$ and show that $s_{n^+} = \bar{a} +_X \bar{b}$ also holds. Since 2 is the beginning of the counting set $\mathbb{N}_+ \setminus \{1\}$, we evidently obtain the inequality $2 \leq n$ $[< n+1]$ with (4.184), and therefore $n+1 > 2$ with the Transitivity Formula for $\leq$ and $<$; thus, the definition of the sequence f yields $a_{n+1} = 0_X$. We therefore obtain the true equations

$$s_{n+1} = \sum_{i=1}^{n+1} a_i = \left(\sum_{i=1}^{n} a_i\right) +_X a_{n+1} = (\bar{a} +_X \bar{b}) +_X 0_X = \bar{a} +_X \bar{b}$$

using the definition of a series, (5.417), the induction assumption together with $a_{n+1} = 0_X$, and finally the definition of a neutral element. As n is arbitrary, we may infer from this the truth of the induction step, so that the proof by mathematical induction is complete.

Because X, $+_X$, $\bar{a}$ and $\bar{b}$ were arbitrary, we may further conclude that the proposed universal sentence a) is true. □

Exercise 5.55. Establish Part b) of Proposition 5.133.

(Hint: Proceed as in the proof of Proposition 5.98, using Corollary 4.49.)

Although the constant tail of the preceding series turns out to be an increasing/decreasing sequence, the underlying series is not necessarily monotone. In order for this to happen, we need make some further assumptions.

Proposition 5.134. *For any set X, any commutative addition $+_X$ on X and any reflexive partial ordering $\leq_X$ of X such that the zero element 0_X of X exists, such that $0_X \leq_X a$ holds for any $a \in X$ and such that the Monotony Law for $+$ and $\leq$ is satisfied, it is true that the series $(\sum_{i=1}^n a_i)_{n\in\mathbb{N}_+}$ generated by any sequence $(a_n)_{n\in\mathbb{N}_+}$ in X is increasing.*

Proof. We take an set X, an arbitrary commutative addition $+_X$ on X, an arbitrary reflexive partial ordering $\leq_X$ of X, and an arbitrary sequence $(a_n)_{n\in\mathbb{N}_+}$ in X, where we assume that the inequality $0_X \leq_X a$ concerning the zero element of X holds for any $a \in X$, and where we assume in addition the Monotony Law for $+$ and $\leq$ to apply. Thus, f defines the series $s = (s_n)_{n\in\mathbb{N}_+} = (\sum_{i=1}^n a_i)_{n\in\mathbb{N}_+}$. Next, we apply the Monotony Criterion for increasing sequences in connection with Exercise 4.29 and Proposition 5.48 to prove that the series s is increasing, that is, we verify

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow s_n \leq_X s_{n+1}). \tag{5.515}$$

For this purpose, we let $n \in \mathbb{N}_+$ be arbitrary and consider the restriction $(a_i \,|\, i \in \{1,\ldots,n+1\})$ of f. Since the terms a_{n+1} and $\sum_{i=1}^n a_i$ are both elements of X, they satisfy $0 \leq_X a_{n+1}$ and $0 \leq_X \sum_{i=1}^{n} a_i$ by assumption. Applying now the assumed monotony law, we obtain

$$0_X +_X \sum_{i=1}^{n} a_i \leq_X a_{n+1} +_X \sum_{i=1}^{n} a_i. \tag{5.516}$$

In view of the definition of a neutral element, the commutativity of $+_X$ and Corollary 5.109e), we may now write the preceding inequality as

$$\sum_{i=1}^{n} a_i \leq_X \sum_{i=1}^{n+1} a_i, \tag{5.517}$$

and then also as the desired $s_n \leq_X s_{n+1}$ by using the definition of a series. Since n was arbitrary, we may therefore conclude that (5.515) is true, which implies that the series $(s_n)_{n\in\mathbb{N}_+}$ is increasing. As X, $+_X$, $\leq_X$ and f were initially arbitrary, we may infer from this finding the truth of the proposition. □

Note 5.30. The preceding proposition holds in particular for every ordered elementary domain.

Proposition 5.135. *For any set X, any commutative addition $+_X$ on X and any reflexive partial ordering $\leq_X$ of X such that the zero element 0_X of X exists, such that $0_X \leq_X a$ holds for any $a \in X$ and such that the Monotony Law for $+$ and $\leq$ is satisfied, and for any elements $\bar{a}, \bar{b} \in X$, it is true that the series generated by the sequence $f = (a_n)_{n\in\mathbb{N}}$ in X defined by (5.361) converges increasingly to the sum of $\bar{a}$ and $\bar{b}$, i.e.*

$$\sum_{i=1}^{\infty} a_n = \bar{a} +_X \bar{b}. \tag{5.518}$$

Proof. Letting X, $\leq_X$, $+_X$, $\bar{a}$ and $\bar{b}$ be arbitrary, assuming $+_X$ to be a commutative addition on X where X contains the zero element 0_X, assuming $(X, \leq_X)$ to be a partially ordered set satisfying $0_X \leq_X a$ for any $a \in X$ as well as the Monotony Law for $+$ and $\leq$, and assuming X to contain $\bar{a}$ as well as $\bar{b}$, we may define the sequence $f = (a_n)_{n\in\mathbb{N}_+}$ in X according to (5.361). Then, the series $s = (s_n)_{n\in\mathbb{N}_+}$ with $s_n = \sum_{i=1}^{n}$ for any $n \in \mathbb{N}_+$ is also defined, and this series is increasing in view of Proposition 5.134. Furthermore, the 2nd tail T_2^s of this series is a constant sequence with value $\bar{a} +_X \bar{b}$, as shown in Proposition 5.133. Therefore, the tail T_2^s converges increasingly to the sum $L = \bar{a} +_X \bar{b}$ in view of Proposition 4.76. Because the underlying sequence s is increasing, we may then apply the Tail Criterion for convergence of an increasing sequence to infer from the previous findings that s converges increasingly to the same limit L, i.e. $L = \lim_{n\to\infty} s_n$, which we may then write also as (5.518) by using Notation 5.22. Since X, $\leq_X$, $+_X$, $\bar{a}$ and $\bar{b}$ were initially arbitrary, we may now finally conclude that the proposition holds. $\square$

In case a series does not have a constant tail, convergence of the series can be effected via the assumption of a complete lattice. Combining the findings of the preceding exercise and of Proposition 4.75 immediately gives us the following result.

Corollary 5.136. *For any sets X, $+_X$, $\leq_X$ and f such that*

1. *$+_X$ is a commutative addition on X,*
2. *X contains the zero element 0_X,*
3. *$(X, \leq_X)$ is a complete lattice satisfying $0_X \leq_X a$ for any $a \in X$ as well as the Monotony Law for $+$ and $\leq$,*
4. *f is a sequence $(a_n)_{n\in\mathbb{N}_+}$ in X,*

it is true that the generated series $s = (s_n)_{n\in\mathbb{N}_+} = (\sum_{i=1}^{n} a_i)_{n\in\mathbb{N}_+}$ is increasingly convergent.

5.6.4. Multiples and powers of natural numbers

Proposition 5.137. *Any natural number n is identical with the n-fold sum of the natural number 1, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \sum_{i=1}^{n} 1 = n). \tag{5.519}$$

Proof. We carry out a proof by mathematical induction. In the base case ($n = 0$), we obtain

$$\sum_{i=1}^{n} 1 = \sum_{i=1}^{0} 1 = 0 = n$$

by applying substitution based on $n = 0$, then (5.409), and finally again substitution based on $n = 0$.

Regarding the induction step, we let $n \in \mathbb{N}$ be arbitrary, make the induction assumption $\sum_{i=1}^{n} 1 = n$, and show that this implies $\sum_{i=1}^{n+1} 1 = n + 1$. Indeed, we obtain the equations

$$\sum_{i=1}^{n+1} 1 = \left(\sum_{i=1}^{n} 1\right) + 1 = n + 1$$

with (5.417) and the induction assumption. Since n was arbitrary, we may therefore conclude that the proposed universal sentence (5.519) is true. □

We then obtain the following result immediately with Notation 5.20.

Corollary 5.138. *The following sentence holds for the semigroup* $(\mathbb{N}, +)$.

$$\forall n\,(n \in \mathbb{N} \Rightarrow n1 = n). \tag{5.520}$$

As a first application of the Generalized Distributive Law for semirings, we establish the fact that multiples of natural numbers may be view as products.

Proposition 5.139. *It is true that*

$$\forall k, n\,(k, n \in \mathbb{N} \Rightarrow nk = n \cdot_{\mathbb{N}} k). \tag{5.521}$$

Proof. Letting $k, n \in \mathbb{N}$ be arbitrary, we obtain the true equations

$$nk = \sum_{i=1}^{n} k = \sum_{i=1}^{n} (k \cdot_{\mathbb{N}} 1) = k \cdot_{\mathbb{N}} \sum_{i=1}^{n} 1 = k \cdot_{\mathbb{N}} n = n \cdot_{\mathbb{N}} k$$

by applying Notation 5.20, the fact that the sequences $(k \,|\, i \in \{1, \ldots, n\})$ and $(k \cdot_{\mathbb{N}} 1 \,|\, i \in \{1, \ldots, n\})$ are identical according to the Equality Criterion for functions because $k = k \cdot_{\mathbb{N}} 1$ holds (for any $i \in \{1, \ldots, n\}$) by virtue of the property of the neutral element 1 with respect to the multiplication on $\mathbb{N}$, the Generalized Distributive Law for semirings, (5.519), and the commutativity of $\cdot_{\mathbb{N}}$. Since k and n were initially arbitrary, we may therefore conclude that the proposition holds, as claimed. □

We see now that any natural number may be written as the sum of a multiple and a 'remainder' in a unique way.

Theorem 5.140 (Division of a natural number with remainder). *For any natural number $g \geq 2$ and for any natural number n, it is true that there exist unique natural numbers q and $r < g$ such that n is the sum of the multiple qg and r, i.e.*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \exists! q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = qg + r)). \tag{5.522}$$

Proof. We first let $g \in \mathbb{N}$ be arbitrary and assume $g \geq 2$ to hold. Evidently, we may write (5.522) also as

$$\begin{aligned} \forall n\,(n \in \mathbb{N} \Rightarrow [&\exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = qg + r) \\ &\wedge\, \forall q, r, q', r'\,([q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = qg + r \\ &\quad \wedge\, q', r' \in \mathbb{N} \wedge\, r' < g \,\wedge\, n = q'g + r'] \Rightarrow [q = q' \,\wedge\, r = r'])]). \end{aligned} \tag{5.523}$$

by using Notation 1.4. Next, we observe in light of the Distributive Law for sentences (1.46), the Distributive Law for quantification (1.74) and (5.521) that the preceding sentence is equivalent to the conjunction

$$\begin{aligned} &\forall n\,(n \in \mathbb{N} \Rightarrow \exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = q \cdot g + r)) \\ &\quad \wedge\, \forall n\,(n \in \mathbb{N} \Rightarrow \forall q, r, q', r'\,([q, r \in \mathbb{N} \wedge\, r < g \,\wedge\, n = q \cdot g + r \\ &\qquad \wedge\, q', r' \in \mathbb{N} \wedge\, r' < g \,\wedge\, n = q' \cdot g + r'] \Rightarrow [q = q' \,\wedge\, r = r'])). \end{aligned} \tag{5.524}$$

To verify the first part

$$\forall n\,(n \in \mathbb{N} \Rightarrow \exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = q \cdot g + r)), \tag{5.525}$$

we carry out a proof by mathematical induction. Considering the base case ($n = 0$), we observe the truth of $0 \in \mathbb{N}$, of $0 < (2 \leq) g$ (in view of (4.168) and the Transitivity Formula for $<$ and $\leq$) and of $0 \cdot g + 0 = 0$, so that the existential sentence

$$\exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, 0 = q \cdot g + r)$$

holds. Then, to prove the induction step

$$\begin{aligned} &\forall n\,(n \in \mathbb{N} \Rightarrow [\exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = q \cdot g + r) \\ &\qquad \Rightarrow \exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n + 1 = q \cdot g + r)]), \end{aligned}$$

we let $n \in \mathbb{N}$ be arbitrary, we make the induction assumption

$$\exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n = q \cdot g + r),$$

and we show that this implies

$$\exists q, r\,(q, r \in \mathbb{N} \,\wedge\, r < g \,\wedge\, n + 1 = q \cdot g + r). \tag{5.526}$$

Because of the induction assumption, there are constants, say $\overline{q}$ and $\overline{r}$ which satisfy $\overline{q}, \overline{r} \in \mathbb{N}$, $\overline{r} < g$, and the equation

$$n = \overline{q} \cdot g + \overline{r}. \tag{5.527}$$

We then obtain the equations

$$\begin{aligned} n + 1 &= (\overline{q} \cdot g + \overline{r}) + 1 \\ &= \overline{q} \cdot g + (\overline{r} + 1) \end{aligned} \tag{5.528}$$

by applying substitution based on (5.527) and then the associativity of the addition on $\mathbb{N}$. Because of (4.157) and (5.217), the inequality $\overline{r} < g$ implies

$\overline{r}+1 \leq g$. Consequently, the disjunction $\overline{r}+1 < g \vee \overline{r}+1 = g$ is true by definition of an induced reflexive partial ordering, which we now use to prove the existential sentence (5.526) by cases.

In the first case of $\overline{r}+1 < g$, the constants $\overline{q}$ and $\overline{r}+1$ satisfy the conjunction of $\overline{q}, \overline{r}+1 \in \mathbb{N}$, $\overline{r}+1 < g$ and $n+1 = \overline{q}\cdot g + (\overline{r}+1)$, so that the existential sentence (5.526) is clearly true in the first case.

In the other case of $\overline{r}+1 = g$, we obtain the equations

$$\begin{aligned} n+1 &= \overline{q}\cdot g + (\overline{r}+1) \\ &= \overline{q}\cdot g + g \\ &= g\cdot\overline{q} + g\cdot 1 \\ &= g\cdot(\overline{q}+1) \\ &= (\overline{q}+1)\cdot g \\ &= (\overline{q}+1)\cdot g + 0. \end{aligned}$$

with (5.528), by applying substitution based on the current case assumption, then the commutativity of the multiplication on $\mathbb{N}$ together with the definition of a neutral element, subsequently the distributivity of the multiplication on $\mathbb{N}$ over the addition on $\mathbb{N}$, then again the commutativity of the multiplication on $\mathbb{N}$, and finally again the definition of a neutral element. Thus, the constants $\overline{q}+1$ and 0 evidently satisfy $(\overline{q}+1), 0 \in \mathbb{N}$, $0 < g$ and $n+1 = (\overline{q}+1)\cdot g + 0$, so that the existential sentence (5.526) is true also for the second case. Since n was arbitrary, we may therefore conclude that the induction step holds, besides the base case, so that the proof of (5.525) by mathematical induction is complete.

We now establish the second part

$$\begin{aligned} &\forall n\,(n \in \mathbb{N} \Rightarrow \forall q, r, q', r'\,([q, r \in \mathbb{N} \wedge r < g \,\wedge\, n = q\cdot g + r \\ &\quad \wedge\, q', r' \in \mathbb{N} \wedge r' < g \,\wedge\, n = q'\cdot g + r'] \Rightarrow [q = q' \,\wedge\, r = r'])). \qquad (5.529) \end{aligned}$$

of the conjunction (5.524). For this purpose, we let $n \in \mathbb{N}$ be arbitrary and let then q, r, q' and r' also be arbitrary such that the conjunction of $q, r \in \mathbb{N}$, $r < g$, $n = q\cdot g + r$, $q', r' \in \mathbb{N}$, $r' < g$ and $n = q'\cdot g + r'$ is true. Here, we may write the previous two equations for n also as

$$\begin{aligned} r + q\cdot g &= n, \\ r' + q'\cdot g &= n, \end{aligned}$$

applying the commutativity of the addition on $\mathbb{N}$. These equations in turn show in light of Note 5.28 that the differences

$$q\cdot g = n - r, \qquad (5.530)$$

$$q'\cdot g = n - r' \qquad (5.531)$$

are defined because the inequalities $r \leq n$ and $r' \leq n$ hold.

As the standard linear ordering of $\mathbb{N}$ is in particular connex, we have the true disjunction

$$q < q' \lor q' < q \lor q = q'. \tag{5.532}$$

We now carry out two proofs by contradiction to demonstrate that the negations of the first and second part of that disjunction are true.

Regarding the first part, we assume the negation of $\neg q < q'$ to hold, so that $q < q'$ follows to be true with the Double negation Law. Then, the disjunction $q < q' \lor q = q'$ also holds, which gives $q \leq q'$ by definition of a reflexive partial ordering. Thus, the difference $q' - q$ is defined, so that we may form the product of the natural number $q' - q$ and the natural number g. We then obtain the equations

$$\begin{aligned}(q' - q) \cdot g &= g \cdot (q' - q) \\ &= (g \cdot q') - (g \cdot q) \\ &= (q' \cdot g) - (q \cdot g) \\ &= (n - r') - (n - r)\end{aligned}$$

by applying the commutativity of the multiplication on $\mathbb{N}$, the Distributive Law for the difference of natural numbers, again the commutativity of the multiplication on $\mathbb{N}$, and then substitutions based on the equations (5.530) – (5.531). The last difference shows that $n - r \leq n - r'$ holds, and we may now prove by contradiction that the inequality $r' \leq r$ is also true. For this purpose, we assume $\neg r' \leq r$ to be true, which yields $r < r'$ with the Negation Formula for $\leq$. Together with the previously established inequality $r' \leq n$, this implies $n - r' < n - r$ with (5.354), and therefore $\neg n - r \leq n - r'$ with the Negation Formula for $\leq$. Evidently, we obtained a contradiction, so that $r' \leq r$ is indeed true. Thus, the conjunction $r \leq n \land r' \leq r$ holds, so that we may apply (5.348) to obtain the equation

$$[(q' - q) \cdot g =] \quad (n - r') - (n - r) = r - r'.$$

The previously established inequality $q < q'$ implies $0 < q' - q$ with (5.352) and then $(0^+ =)\ 1 \leq q' - q$ with (4.157). Because of $0 < g$, we may now use the Monotony Law for $\cdot$ and $\leq$ to obtain

$$1 \cdot g \leq (q' - q) \cdot g \quad [= r - r'],$$

that is, $g \leq r - r'$ (in view of the definition of a neutral element). Furthermore, the fact $0 \leq r'$ implies $0 + (r - r') \leq r' + (r - r')$ with the Monotony Law for $+$ and $\leq$, which we may write also as

$$r - r' \leq (r - r') + r'.$$

by applying the definition of a neutral element and the commutativity of the addition on $\mathbb{N}$. Here, $(r - r') + r' = r$ holds according to (5.343), where we initially assumed $r < g$ to be true. Consequently, we obtain the inequalities $r - r' \leq r < g$, which give $r - r' < g$ by means of the Transitivity Formula for $\leq$ and $<$, and then $\neg g \leq r - r'$ with the Negation Formula for $<$. This finding contradicts the previously established inequality $g \leq r - r'$, so that the proof of $\neg q < q'$ is complete.

Regarding the second part of the disjunction (5.532), we now assume the negation of $\neg q' < q$, so that the Double Negation Law yields now $q' < q$. We may actually apply exactly the same line of arguments to obtain a contradiction, where the roles of q and q' as well as the roles of r and r' are interchanged. To begin with, the preceding inequality evidently gives $q' \leq q$, so that the difference $q - q'$ and then the product $(q - q') \cdot g$ are defined. Clearly, we obtain then the true equations

$$\begin{aligned}(q - q') \cdot g &= g \cdot (q - q') \\ &= (g \cdot q) - (g \cdot q') \\ &= (q \cdot g) - (q' \cdot g) \\ &= (n - r) - (n - r').\end{aligned}$$

The difference $(n - r) - (n - r')$ reveals the inequality $n - r' \leq n - r$, and we may show via contradiction also that $r \leq r'$ holds. Indeed, the assumption $\neg r \leq r'$ gives $r' < r$, which implies together with $r \leq n$ the truth of $n - r < n - r'$, so that $\neg n - r' \leq n - r$ holds, in contradiction to the previously obtained $n - r' \leq n - r$. Thus, the proof of $r \leq r'$ is complete, so that the conjunction $r' \leq n \wedge r \leq r'$ is true. Then, we may infer from this finding the truth of the equations

$$[(q - q') \cdot g =] \quad (n - r) - (n - r') = r' - r.$$

Let us now observe that $q' < q$ gives $0 < q - q'$ and subsequently $(0^+ =) \; 1 \leq q - q'$, which further implies (with $0 < g$)

$$1 \cdot g \leq (q - q') \cdot g \quad [= r' - r],$$

that is, $g \leq r' - r$. Moreover, $0 \leq r$ implies $0 + (r' - r) \leq r + (r' - r)$, so that

$$r' - r \leq (r' - r) + r,$$

where $(r' - r) + r = r'$ and $r' < g$ hold. Thus, we have $r' - r \leq r' < g$, which inequalities result in $r' - r < g$, with the consequence that the negation $\neg g \leq r' - r$ is true. We therefore obtained a contradiction, which finding completes the proof of $\neg q' < q$.

We thus showed that the first and the second part of the disjunction (5.532) are false, so that its third part $q = q'$ is true, proving the first part of the desired conjunction $q = q' \wedge r = r'$ in (5.529). Let us now apply substitution based on the equation $q = q'$ to write the initially assumed equation $n = q' \cdot g + r'$ as $n = q \cdot g + r'$, and let us next combine the latter with the other assumed equation $n = q \cdot g + r$ to obtain

$$q \cdot g + r = q \cdot g + r'.$$

Then, an application of the Cancellation Law for $+_{\mathbb{N}}$ yields already the desired equation $r = r'$. Thus, the proof of the conjunction $q = q' \wedge r = r'$, and thus the proof of the second implication in (5.529), is complete. Because q, r, q' and r' are arbitrary, we may therefore conclude that the universal sentence with respect to these variables is true, which proves in turn the implication based in the antecedent $n \in \mathbb{N}$. Since n is arbitrary, we may now further conclude that (5.529) holds, and this completes the proof of the conjunction (5.524). As this sentence is equivalent to (5.522), we may infer from that conjunction the truth of the stated theorem. $\square$

Note 5.31. In the equation $n = qg + r$, we call the natural number

- n the *dividend*,
- g the *divisor*,
- q the *quotient*, and
- r the *remainder*.

We also say that n divides by g with remainder r.

The following result leads to the distinction of 'even' and 'odd' natural numbers.

Proposition 5.141. *It is true that any natural number n divides by 2 either with remainder 0 or with remainder 1, i.e.*

$$\begin{aligned}\forall n\,(n \in \mathbb{N} \Rightarrow ([\exists q\,(q \in \mathbb{N} \wedge n = q2) \vee \exists q\,(q \in \mathbb{N} \wedge n = q2 + 1)]\\ \wedge \neg[\exists q\,(q \in \mathbb{N} \wedge n = q2) \wedge \exists q\,(q \in \mathbb{N} \wedge n = q2 + 1)])).\end{aligned} \tag{5.533}$$

Proof. We let $n \in \mathbb{N}$ be arbitrary, so that there exist because of Theorem 5.140 unique natural numbers $\bar{q}$ and $\bar{r} < 2$ satisfying

$$n = \bar{q}2 + \bar{r}. \tag{5.534}$$

Here, $r \in \mathbb{N}$ implies $0 \leq \bar{r}$ with (4.187), so that the disjunction $0 < \bar{r} \vee 0 = \bar{r}$ follows to be true with the Characterization of an induced irreflexive partial ordering. We use this disjunction to prove the existential sentence in (5.533).

The first case $0 < \bar{r}$ implies $[1 =]\ 0^+ \leq \bar{r}$ with (2.291) and (4.157). Because of (2.292), we may write $\bar{r} < 2$ also as $\bar{r} < 1^+$. Then, the conjunction of $1 \leq \bar{r}$ and $\bar{r} < 1^+$ implies $\bar{r} = 1$ with (4.173). Due to this equation, (5.534) yields $n = \bar{q}2 + 1$ via substitution, which shows in light of $\bar{q} \in \mathbb{N}$ that the existential sentence $\exists q\,(q \in \mathbb{N} \wedge n = q2+1)$ holds. The disjunction

$$\exists q\,(q \in \mathbb{N} \wedge n = q2) \vee \exists q\,(q \in \mathbb{N} \wedge n = q2 + 1) \tag{5.535}$$

is then also true, proving the first part of the conjunction in (5.533) for the first case.

The second case $0 = \bar{r}$ gives us $m = \bar{q}2 + 0$ by means of substitution in (5.534), so that the existential sentence $\exists q\,(q \in \mathbb{N} \wedge n = q2)$ holds now. Consequently, the disjunction (5.535) and thus the first part of the conjunction in (5.533) hold also for the second case.

It now remains for us to establish the negation in (5.533), which we prove by contradiction. Assuming the negation of that negation to be true, it follows with the Double Negation Law that there is a natural number, say q', with $n = q'2$, and that there is a natural number, say q'', satisfying $n = q''2 + 1$. The first of these equations clearly shows that the remainder is $r' = 0$, whereas the remainder in the other equation is $r'' = 1$. Since the quotient for n is unique (according to Theorem 5.140), we obtain $q' = q''$, so that substitution gives $n = q'2 + 1$. Since $n = q'2 + 0$ also holds, and because the remainder for the division of n by 2 is unique, we also obtain $1 = 0$, in contradiction to the fact $0 \neq 1$ shown in (4.165). This finding completes the proof of the negation in (5.533), and as n was arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Note 5.32. By convention, we will write for instance $2q$ instead of $q2$, putting the explicit natural number in front.

The preceding proposition gives rise to the next definition.

Definition 5.27 (Even & odd natural number). We say that a natural number n

(1) is *even* iff n divides by 2 with remainder 0, i.e. iff

$$\exists q\,(q \in \mathbb{N} \wedge n = 2q). \tag{5.536}$$

(2) is *odd* iff n divides by 2 with remainder 1, i.e. iff

$$\exists q\,(q \in \mathbb{N} \wedge n = 2q + 1). \tag{5.537}$$

Proposition 5.142. *Any power of* 3 *is odd, that is,*

$$\forall n\,(n \in \mathbb{N} \Rightarrow \exists q\,(q \in \mathbb{N} \wedge 3^n = 2q+1)). \tag{5.538}$$

Proof. We apply a proof by mathematical induction. We obtain for the base case ($n = 0$) the equations

$$3^n = 3^0 = 1 = 0+1 = 2 \cdot 0 + 1 = 2n+1$$

by applying substitution, (5.476), the definition of a neutral element, the Cancellation Law for 0, and finally again substitution together with (5.521). Thus, the existential sentence in (5.538) is clearly true for $n = 0$.

To establish the induction step, we let $n \in \mathbb{N}$ be arbitrary, assume that there exists a natural number, say $\bar{q}$, such that $3^n = 2\bar{q}+1$ holds, and show that this implies the existential sentence

$$\exists q\,(q \in \mathbb{N} \wedge 3^{n+1} = 2q+1). \tag{5.539}$$

Let us now observe the truth of the equations

$$\begin{aligned}
3^{n+1} &= 3^n + 3 \\
&= (2\bar{q}+1) + 3 \\
&= 3 \cdot 2\bar{q} + 3 \cdot 1 \\
&= 3 \cdot (2 \cdot \bar{q}) + (2+1) \cdot 1 \\
&= 2 \cdot (3 \cdot \bar{q}) + (2 \cdot 1 + 1) \\
&= 2 \cdot (3 \cdot \bar{q} + 1) + 1 \\
&= 2(3 \cdot \bar{q} + 1) + 1
\end{aligned}$$

using (5.480), the induction assumption, the commutativity of $+_{\mathbb{N}}$ together with the distributivity of $\cdot_{\mathbb{N}}$ over $+_{\mathbb{N}}$, (5.521) alongside (2.293) in connection with (5.217), the associativity and commutativity of $\cdot_{\mathbb{N}}$ jointly with (5.475), the associativity of $+_{\mathbb{N}}$ together with the distributivity of $\cdot_{\mathbb{N}}$ over $+_{\mathbb{N}}$, and finally again (5.521). Because $3 \cdot \bar{q} + 1$ is a natural number, the desired existential sentence (5.539) holds, and since n was arbitrary, we may therefore conclude that the induction step is true, besides the base case. We thus completed the proof of the proposed universal sentence (5.538). □

Exercise 5.56. Show for any positive natural number n that the n-th power of 2 is even, that is,

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \exists q\,(q \in \mathbb{N} \wedge 2^n = 2q)). \tag{5.540}$$

(Hint: Use some of the arguments in the proof of Proposition 5.142.)

5.6.5. Laws for powers in ordered elementary domains

Proposition 5.143. *For any ordered elementary domain $(X,+,\cdot,<)$ it is true that any element in X strictly between the zero and the unity element is greater than its square, i.e.*

$$\forall a\,([a \in X \ \wedge\ 1_X < a] \Rightarrow a < a^2). \tag{5.541}$$

Proof. We let X, $+$, $\cdot$ and $<$ be arbitrary sets, assume that $(X,+,\cdot,<)$ is an ordered elementary domain, let a also be arbitrary, and assume moreover $a \in X$ and $1_X < a$ to be true. Recalling the truth of $1_X \neq 0_X$ in view of the Distinctness of the zero element and the unity element in ordered elementary domains, we now obtain with (5.275) the inequality $0_X < 1_X$. Then, we see in light of the Linear ordering of ordered elementary domains that $<$ is transitive, so that $0_X < 1_X$ and $1_X < a$ imply $0_X < a$. Based on the evident fact $0_X, 1_X, a \in X$ and the inequalities $0_X < a$ and $1_X < a$, the Monotony Law for $\cdot$ and $<$ yields $1_X \cdot a < a \cdot a$, which we may write as $a < a^2$ by applying the definition of a neutral element and (5.478). This inequality proves the implication in (5.541), and since a is arbitrary, we may therefore conclude that the universal sentence (5.541) holds. Then, as X, $+$, $\cdot$ and $<$ were initially arbitrary sets, we may further conclude that the proposition is true. □

Exercise 5.57. Prove the following sentences for any ordered elementary domain $(X,+,\cdot,<)$.

$$\forall a\,([a \in X \ \wedge\ 0_X < a < 1_X] \Rightarrow a^2 < a). \tag{5.542}$$

$$\forall a\,([a \in X \ \wedge\ 0_X < a \leq 1_X] \Rightarrow a^2 \leq a). \tag{5.543}$$

$$\forall a\,([a \in X \ \wedge\ 1_X \leq a] \Rightarrow a \leq a^2). \tag{5.544}$$

(Hint: Use similar arguments as in the proof of Proposition 5.143, using also (5.293) and (3.232).)

Lemma 5.144. *The following sentences are true for any ordered elementary domain $(X,+,\cdot,<)$.*

$$\forall a,b\,([a,b \in X \ \wedge\ a < b] \Rightarrow \forall n\,(n \in \mathbb{N}_+ \Rightarrow a^n < b^n)), \tag{5.545}$$

$$\forall a,m\,([a \in X \ \wedge\ 1_X < a \ \wedge\ m \in \mathbb{N}] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow [m <_{\mathbb{N}} n \Rightarrow a^m < a^n])). \tag{5.546}$$

Proof. First we let X, $+$, $\cdot$ and $<$ be arbitrary and assume that $(X,+,\cdot,<)$ is an ordered elementary domain.

Concerning (5.545), we let also a and b be arbitrary and assume moreover that a and b are elements of X satisfying $a < b$. Let us observe that

(5.276) gives the disjunction $0_X < a \lor a = 0_X$ and therefore $0_X \leq a$ by definition of the total ordering $\leq$ induced by the linear ordering $<$ of X; the conjunction of the preceding inequality and the assumed inequality $a < b$ now implies $0_X < b$ with the Transitivity Formula for $\leq$ and $<$. Next, we prove the universal sentence with respect to n by carrying out mathematical induction. Regarding the base case ($n = 1$), we simply observe that we may write the assumed $a < b$ also as $a^1 < b^1$ because of (5.477), so that the desired inequality $a^n < b^n$ holds for $n = 1$.

Concerning the induction step, we let $n \in \mathbb{N}_+$ be arbitrary, make the induction assumption $a^n < b^n$, and show that this implies $a^{n+1} < b^{n+1}$. We prove this inequality by cases based on the disjunction $0_X < a^n \lor a^n = 0_X$, which is true because of (5.276) and the fact that a^n is an element of X by definition of an n-th power/n-fold binary operation (on X).

In the first case $0_X < a^n$, we have in light of the Monotony Law for $\cdot$ and $<$ that $a < b$ implies $a \cdot a^n < b \cdot a^n$, which yields with the commutativity of the multiplication $a^n \cdot a < a^n \cdot b$.

$$a^n \cdot a < a^n \cdot b. \tag{5.547}$$

Then, the previously established inequality $0_X < b$ implies together with the induction assumption $a^n < b^n$ the truth of the inequality

$$a^n \cdot b < b^n \cdot b \tag{5.548}$$

using again the Monotony Law for $\cdot$ and $<$. Since the linear ordering $<$ of X is transitive, the conjunction of the true inequalities (5.547) and (5.548) implies $a^n \cdot a < b^n \cdot b$, and therefore $a^{n+1} < b^{n+1}$ with (5.480), as desired.

In the other case $a^n = 0_X$, we obtain on the one hand the equations

$$\begin{aligned} a^{n+1} &= a^n \cdot a \\ &= 0_X \cdot a \\ &= 0_X \end{aligned} \tag{5.549}$$

by applying (5.480), substitution and the Cancellation Law for 0_X. On the other hand, the induction assumption $a^n < b^n$ gives via substitution $0_X < b^n$. This finding implies with the previously obtained $0_X < b$ and the Monotony Law for $\cdot$ and $<$ the true inequality $0_X \cdot b < b^n \cdot b$ and consequently $0_X < b^{n+1}$ with the Cancellation Law for 0_X and with (5.480). Now, substitution based on the equation (5.549) yields the desired $a^{n+1} < b^{n+1}$ again, so that the proof by cases is complete. As n was arbitrary, we may therefore conclude that the induction step is true (besides the base case), so that the proof by mathematical induction is also complete. Since a and

b were arbitrary, the universal sentence (5.545) follows then to be true.

Concerning (5.546), we take arbitrary a and m, assume $a \in X$, $1_X < a$ and $m \in \mathbb{N}$ to be true, and apply then a proof by mathematical induction. To establish the base case $n = 0$, we observe that $m <_{\mathbb{N}} 0$ is false according to (4.188), so that the implication $m <_{\mathbb{N}} 0 \Rightarrow a^m < a^0$ is true (having a false antecedent). To prove the induction step, we let $n \in \mathbb{N}$ be arbitrary, make the induction assumption

$$m <_{\mathbb{N}} n \Rightarrow a^m < a^n, \tag{5.550}$$

and we show that

$$m <_{\mathbb{N}} n + 1 \Rightarrow a^m < a^{n+1}, \tag{5.551}$$

follows to be true. To do this, we assume $m <_{\mathbb{N}} n + 1$ to be true, which implies $m+1 \leq_{\mathbb{N}} n+1$ with (4.157) and (5.217), so that we obtain $m \leq_{\mathbb{N}} n$ according to (4.159). By definition of an induced reflexive partial ordering, the preceding inequality yields now $m <_{\mathbb{N}} n \vee m = n$, which disjunction we use to prove the desired consequent $a^m < a^{n+1}$ by cases. Before considering the two cases, we observe that the fact $0_X < 1_X$ (see Corollary 5.69) and the assumed $1_X < a$ imply $0_X < a$ with the transitivity of the linear ordering $<$ of X. This inequality in turn implies $0_X \neq a$ with (5.275), which finding gives (with $a \in X$ and $n \in \mathbb{N}$) the inequality $a^n \neq 0_X$ because of (5.495), and therefore $0_X < a^n$ again with (5.275). Consequently, we may apply the Monotony Law for $\cdot$ and $<$ to infer from the assume $1_X < a$ the truth of $1_X \cdot a^n < a \cdot a^n$, which we may write also as $a^n < a^n \cdot a$ by using the definition of a neutral element as well as the commutativity of the multiplication on X. Then, this inequality yields $a^n < a^{n+1}$ with (5.480).

Now, the first case $m <_{\mathbb{N}} n$ implies $a^m < a^n$ with the induction assumption (5.550); since $a^n < a^{n+1}$ also holds, the transitivity of $<$ gives $a^m < a^{n+1}$. In the other case of $m = n$, we obtain via substitution $a^m = a^n$ ($< a^{n+1}$), so that $a^m < a^{n+1}$ is again true. Thus, the proof by cases is already complete, and the truth of $a^m < a^{n+1}$ establishes the truth of the implication (5.551). As n is arbitrary, we may therefore conclude that the induction step holds, completing the proof of the universal sentence with respect to n in (5.546). Since m and a are also arbitrary, we may further conclude that thhe universal sentence (5.546) is true.

Because X, $+$, $\cdot$ and $<$ were initially arbitrary sets, we may now finally conclude that the lemma holds. □

Corollary 5.145. *The following sentence is true for any ordered elementary domain* $(X, +, \cdot, <)$*.*

$$\forall a, b\,([a, b \in X \,\wedge\, a \leq b] \Rightarrow \forall n\,(n \in \mathbb{N}_+ \Rightarrow a^n \leq b^n)). \tag{5.552}$$

Proof. Letting X, $+$, $\cdot$, $<$, a and b be arbitrary such that $(X, +, \cdot, <)$ is an ordered elementary domain and such that $a, b \in X$ as well as $a \leq b$ holds, and letting n be arbitrary such that $n \in \mathbb{N}_+$ is true, we first observe that the assumption $a \leq b$ implies the truth of the disjunction $a < b \lor a = b$. On the one hand, if $a < b$ is true, then we obtain $a^n < b^n$ with Lemma 5.144; consequently, the disjunction $a^n < b^n \lor a^n = b^n$ is also true, which in turn gives the desired inequality $a^n \leq b^n$. On the other hand, if $a = b$ is true, then we obtain $a^n = b^n$ via substitution, so that the disjunction $a^n < b^n \lor a^n = b^n$ is again true. Thus, $a^n \leq b^n$ holds in both cases, and since n is arbitrary, we may therefore conclude that the universal sentence with respect to n holds. Then, as a and b are also arbitrary, we may further conclude that the universal sentence (5.552) is true. Because X, $+$, $\cdot$ and $<$ are arbitrary as well, we may finally conclude that the corollary holds. □

Exercise 5.58. Verify for any ordered elementary domain $(X, +, \cdot, <)$ the following sentence.

$$\forall a, m\,([a \in X \land 1_X \leq a \land m \in \mathbb{N}] \Rightarrow \forall n\,(n \in \mathbb{N} \Rightarrow [m \leq_{\mathbb{N}} n \Rightarrow a^m \leq a^n])). \tag{5.553}$$

(Hint: Proceed in analogy to the proof of Corollary 5.145.)

Theorem 5.146 (Monotony Laws for the base & exponent and for $<$ & $\leq$ in ordered elementary domains). *The following laws hold for any ordered elementary domain $(X, +, \cdot, <)$.*

a) **Monotony Law for the base and $<$:**

$$\forall a, b, n\,([a, b \in X \land n \in \mathbb{N}_+] \Rightarrow [a < b \Leftrightarrow a^n < b^n]). \tag{5.554}$$

b) **Monotony Law for the exponent and $<$:**

$$\forall a, m, n\,([a \in X \land 1_X < a \land m, n \in \mathbb{N}] \Rightarrow [m <_{\mathbb{N}} n \Leftrightarrow a^m < a^n]). \tag{5.555}$$

c) **Monotony Law for the base and $\leq$:**

$$\forall a, b, n\,([a, b \in X \land n \in \mathbb{N}_+] \Rightarrow [a \leq b \Leftrightarrow a^n \leq b^n]). \tag{5.556}$$

d) **Monotony Law for the exponent and $\leq$:**

$$\forall a, m, n\,([a \in X \land 1_X < a \land m, n \in \mathbb{N}] \Rightarrow [m \leq_{\mathbb{N}} n \Leftrightarrow a^m \leq a^n]). \tag{5.557}$$

Exercise 5.59. Prove Theorem 5.146.

(Hint: Apply proofs by contradiction using Lemma 5.144, Corollary 5.145 and Exercise 5.58 in connection with Theorem 3.77.)

Proposition 5.147. *The following law holds for any ordered elementary domain* $(X, +, \cdot, <)$*.*

$$\forall a, m, n\,([a \in X \wedge 1_X < a \wedge m, n \in \mathbb{N}] \Rightarrow [a^m = a^n \Leftrightarrow m = n]). \quad (5.558)$$

Proof. We let $X, +, \cdot, <, a, m$ and n be arbitrary, we assume that $(X, +, \cdot, <)$ is an ordered elementary domain, and we also assume $a \in X$, $1_X < a$ and $m, n \in \mathbb{N}$ to be true. We now prove the first part ('$\Rightarrow$') of the stated equivalence by contraposition, assuming $m \neq n$ to hold. Since the standard linear ordering of $\mathbb{N}$ is in particular connex, the preceding inequality shows that $m <_{\mathbb{N}} n \vee n <_{\mathbb{N}} m$ is true, which disjunction we now use to prove $a^m \neq a^n$ by cases. On the one hand, the case $m <_{\mathbb{N}} n$ gives $a^m < a^n$ with (5.555) in view of the previously made assumptions $a \in X$, $1_X < a$ and $m, n \in \mathbb{N}$. Then, since the linear ordering $<$ of X is comparable and satisfies thus Theorem 3.49, we may infer from $a^m < a^n$ the truth of the desired inequality $a^m \neq a^n$. On the other hand, the case $n <_{\mathbb{N}} m$ evidently yields $a^n < a^m$ and therefore $a^n \neq a^m$ (applying the same arguments as for the first case), so that $a^m \neq a^n$ follows again to be true. Thus, the proof of the implication $a^m = a^n \Rightarrow m = n$ by contraposition is complete.

Regarding the second part ('$\Leftarrow$') of the equivalence in (5.558), we simply observe that assuming $m = n$ to be true yields already the desired $a^m = a^n$ via substitution.

Then, since X, $+$, $\cdot$, $<$, a, m and n were arbitrary, we may therefore conclude that the proposed universal sentence is true. □

Exercise 5.60. Verify the following sentence for any ordered elementary domain $(X, +, \cdot, <)$.

$$\forall a, b, n\,([a, b \in X \wedge n \in \mathbb{N}_+] \Rightarrow [a^n = b^n \Rightarrow a = b]). \quad (5.559)$$

(Hint: Use similar arguments as in the proof of Proposition 5.147.)

Exercise 5.61. Show for any natural number $p > 1$, any natural number m and any function $c : \{1, \ldots, m+1\} \to \mathbb{N}$ that there exists a unique function s with domain $\{1, \ldots, m+1\}$ and values satisfying

$$\forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow s(i) = c_i \cdot p^{i-1}), \quad (5.560)$$

and show that s is a sequence in $\mathbb{N}$.

(Hint: Use Function definition by replacement in connection with (4.276), Corollary 5.88, and (1.109).)

Theorem 5.148 (p-adic expansion of positive natural numbers). *It is true for any for any natural number $p > 1$ that*

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \exists! m, c\,(m \in \mathbb{N} \,\wedge\, c : \{1, \ldots, m+1\} \to \mathbb{N} \tag{5.561}$$
$$\wedge\, \forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow c_i < p) \,\wedge\, c_{m+1} \neq 0 \,\wedge\, n = \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}])).$$

Proof. We take an arbitrary natural number p, assuming $1 < p$ to be true, and we prove

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow [n < p \Rightarrow \exists! m, c\,(m \in \mathbb{N} \,\wedge\, c : \{1, \ldots, m+1\} \to \mathbb{N} \tag{5.562}$$
$$\wedge\, \forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow c_i < p) \,\wedge\, c_{m+1} \neq 0 \,\wedge\, n = \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}])]),$$

taking an arbitrary positive natural number n and assuming then $n < p$ to be true. Let us consider the natural number

$$\bar{m} = 0 \tag{5.563}$$

and the singleton $\bar{c} = \{(1, n)\}$. The latter constitutes a function from

$$\{1\} = \{1, \ldots, 1\} = \{1, \ldots, 0+1\} = \{1, \ldots, \bar{m}+1\}$$

to $\{n\}$ according to Corollary 3.156, using the definition of an initial segment of $\mathbb{N}_+$ and the fact that 0 is the neutral element of $\mathbb{N}$ with respect to the addition on $\mathbb{N}$. Here, we notice that $(1, n) \in \{(1, n)\}$ $[= \bar{c}]$ holds, which we may write in function/sequence notation as $n = \bar{c}_1$. As $n \in \mathbb{N}_+$ implies $\{n\} \subseteq \mathbb{N}+$ with (2.184) and since the inclusion $\mathbb{N}_+ \subseteq \mathbb{N}$ is true according to (2.308), we therefore obtain the inclusion $\{n\} \subseteq \mathbb{N}$ with (2.13), which shows that $\mathbb{N}$ is also a codomain of $\bar{c}$. We thus have

$$\bar{c} : \{1, \ldots, \bar{m}+1\} \to \mathbb{N}. \tag{5.564}$$

Let us verify that $\bar{m}$ and $\bar{c}$ satisfy

$$\forall i\,(i \in \{1, \ldots, \bar{m}+1\} \Rightarrow \bar{c}_i < p). \tag{5.565}$$

We take an arbitrary i and assume $i \in \{1, \ldots, \bar{m}+1\}$ $[= \{1\}]$ to be true, so that we obtain $i = 1$ with (2.169). We therefore have

$$\bar{c}_i = \bar{c}_1 = n\ [< p],$$

and thus the desired consequent of the implication in (5.563). Since i was arbitrary, we may then infer from this indeed the truth of the universal sentence (5.565). Let us also observe the truth of

$$\bar{c}_{\bar{m}+1} = \bar{c}_{0+1} = \bar{c}_1 = n\ [\in \mathbb{N}_+],$$

which shows in light of (2.307) that $\bar{c}_{\bar{m}+1} \notin \{0\}$ holds, so that (2.169) yields

$$\bar{c}_{\bar{m}+1} \neq 0. \tag{5.566}$$

Furthermore, we obtain the equations

$$\begin{aligned}\sum_{i=1}^{\bar{m}+1}[\bar{c}_i \cdot p^{i-1}] = \sum_{i=1}^{0+1}[\bar{c}_i \cdot p^{i-1}] = \sum_{i=1}^{1}[\bar{c}_i \cdot p^{i-1}] = \bar{c}_1 \cdot p^{1-1} = n \cdot p^0 = n \cdot 1 \\ = n\end{aligned}$$

by using (5.563), the fact that 0 is the neutral element with respect to the addition on $\mathbb{N}$, (5.411), (5.345), (5.476), and the fact that 1 is the neutral element with respect to the multiplication on $\mathbb{N}$. Because of (5.563) – (5.566), we now see that the existential part of the uniquely existential sentence in (5.561) holds for the first case $n < p$.

To establish the uniqueness part, we take arbitrary m, c, m', c' satisfying $m, m' \in \mathbb{N}$, $c : \{1, \ldots, m+1\} \to \mathbb{N}$, $c' : \{1, \ldots, m'+1\} \to \mathbb{N}$, the universal sentences

$$\forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow c_i < p), \tag{5.567}$$

$$\forall i\,(i \in \{1, \ldots, m'+1\} \Rightarrow c'_i < p), \tag{5.568}$$

the inequalities $c_{m+1} \neq 0$ and $c'_{m'+1} \neq 0$ and the equations

$$n = \sum_{i=1}^{m+1}[c_i \cdot p^{i-1}] \tag{5.569}$$

$$n = \sum_{i=1}^{m'+1}[c'_i \cdot p^{i-1}] \tag{5.570}$$

hold. According to (1.118), the task is now to show that $m = m'$ and $c = c'$ follow to be true. We first prove $m = 0$ by contradiction, assuming $m \neq 0$ to be true. We may write the sum (5.569) in its recursive form as

$$\begin{aligned}\sum_{i=1}^{m+1}[c_i \cdot p^{i-1}] &= \sum_{i=1}^{m}[c_i \cdot p^{i-1}] + [c_{m+1} \cdot p^{[m+1]-1}] \\ &= \sum_{i=1}^{m}[c_i \cdot p^{i-1}] + [c_{m+1} \cdot p^{m}] \end{aligned} \tag{5.571}$$

according to (5.417) and using also (5.344). Here, the previously assumed $c_{m+1} \neq 0$ implies $0 < c_{m+1}$ with (5.328), because the term c_{m+1} of the sequence $\bar{c}$ in $\mathbb{N}$ is evidently a natural number. We therefore obtain $[0^+ =]\ 1 \leq c_{m+1}$ with (2.291) and (4.157). Furthermore, because $0 < 1$ holds in view of (4.164) and because we initially assumed $1 < p$ to be true, we obtain $0 < p$ with the transitivity of the standard linear ordering of $\mathbb{N}$. Together with $1 \leq c_{m+1}$, this implies now $1 \cdot p \leq c_{m+1} \cdot p$ with the Monotony Law (5.293), and therefore evidently

$$p \leq c_{m+1} \cdot p. \tag{5.572}$$

Moreover, the previous assumption $m \neq 0$ implies $0 < m$ again with (5.328), consequently $[0^+ =]\ 1 \leq m$ with (2.291) and (4.157). Because if $1 < p$, the inequality $1 \leq m$ yields $p^1 \leq p^m$ with the Monotony Law for the exponent and $\leq$, consequently $p \leq p^m$ according to (5.477). Now, the previously established $0 < c_{m+1}$ and $p \leq p^m$ imply $p \cdot c_{m+1} \leq p^m \cdot c_{m+1}$ with the Monotony Law (5.293), and therefore

$$c_{m+1} \cdot p \leq c_{m+1} \cdot p^m \tag{5.573}$$

with the commutativity of the multiplication on $\mathbb{N}$. The conjunction of (5.572) and (5.573) further implies $p \leq c_{m+1} \cdot p^m$ with the transitivity of the standard total ordering of $\mathbb{N}$, and this finding implies in conjunction with the current case assumption $n < p$ that

$$n < c_{m+1} \cdot p^m \tag{5.574}$$

holds, using the Transitivity Formula for $<$ and $\leq$. Next, we observe that the sum $\sum_{i=1}^{m}[c_i \cdot p^{i-1}]$ is a natural number, so that $0 \leq \sum_{i=1}^{m}[c_i \cdot p^{i-1}]$ is true as shown by (4.187). We therefore obtain with the Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$

$$c_{m+1} \cdot p^m \leq \sum_{i=1}^{m}[c_i \cdot p^{i-1}] + [c_{m+1} \cdot p^m] \tag{5.575}$$

Another application of the Transitivity Formula for $<$ and $\leq$ to (5.574) and (5.575) gives us now

$$n < \sum_{i=1}^{m}[c_i \cdot p^{i-1}] + [c_{m+1} \cdot p^m],$$

so that substitution based on (5.571) yields

$$n < \sum_{i=1}^{m+1}[c_i \cdot p^{i-1}].$$

Because the equation (5.569) is also true by assumption, we obtained a contradiction in view of the fact that the conjunction of these two sentences is false, because the standard linear ordering of $\mathbb{N}$ satisfies the Characterization of comparability. We thus completed the proof of $m = 0$ by contradiction. We may now prove also $m' = 0$ by contradiction by simply replacing in the preceding proof of $m = 0$ the constants m and c by m' and c', respectively. We therefore obtain via substitution $m = m'$, as desired. Consequently, the functions c and c' share the same domain

$$\{1, \ldots, m + 1\} = \{1, \ldots, m' + 1\} = \{1, \ldots, 0 + 1\} = \{1, \ldots, 1\} = \{1\},$$

and the assumed equations (5.569) – (5.570) evidently simplify to

$$n = \sum_{i=1}^{0+1}[c_i \cdot p^{i-1}] = \sum_{i=1}^{1}[c_i \cdot p^{i-1}] = c_1 \cdot p^{1-1} = c_1 \cdot p^0 = c_1 \cdot 1 = c_1$$

and

$$n = \sum_{i=1}^{0+1}[c'_i \cdot p^{i-1}] = \sum_{i=1}^{1}[c'_i \cdot p^{i-1}] = c'_1 \cdot p^{1-1} = c'_1 \cdot p^0 = c'_1 \cdot 1 = c'_1.$$

We are now in a position to conveniently prove $c = c'$ by means of the Equality Criterion for functions, letting i be an arbitrary element of their common domain $\{1\}$. We therefore obtain $i = 1$ with (2.169), and then the equations

$$c_i = c_1 = n = c'_1 = c'_i$$

by applying substitutions based on the previously found equations. Since i is arbitrary, we may therefore conclude that the functions c and c' are indeed identical. In conjunction with $m = m'$, this implies now the truth of the uniqueness part because m, c, m' and c' were arbitrary. Thus, the uniquely existential sentence in (5.562) is true, proving the implication based on the antecedent $n < p$. As n was initially arbitrary, we may now further conclude that the universal sentence (5.562) holds.

Next, we demonstrate the truth of the universal sentence

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow [p \leq n \Rightarrow \exists! m, c\,(m \in \mathbb{N} \,\wedge\, c : \{1, \ldots, m + 1\} \to \mathbb{N} \tag{5.576}$$
$$\wedge\, \forall i\,(i \in \{1, \ldots, m + 1\} \Rightarrow c_i < p) \,\wedge\, c_{m+1} \neq 0 \,\wedge\, n = \sum_{i=1}^{m+1}[c_i \cdot p^{i-1}])]),$$

by carrying out a proof by strong induction. For this purpose, we let $n \in \mathbb{N}_+$

be arbitrary, make the induction assumption

$$\forall k\,([k \in \mathbb{N}_+ \wedge k < n] \Rightarrow [p \leq k \Rightarrow \exists! m, c\,(m \in \mathbb{N} \wedge c : \{1, \ldots, m+1\} \to \mathbb{N}$$
$$\wedge\ \forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow c_i < p)\ \wedge\ c_{m+1} \neq 0\ \wedge\ k = \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}])]),$$

and show that this implies the truth of

$$p \leq n \Rightarrow \exists! m, c\,(m \in \mathbb{N}\ \wedge\ c : \{1, \ldots, m+1\} \to \mathbb{N} \qquad (5.577)$$
$$\wedge\ \forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow c_i < p)\ \wedge\ c_{m+1} \neq 0\ \wedge\ n = \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}]).$$

We prove this implication directly, assuming that $p \leq n$ is true. According to the Division of a natural number with remainder, it follows from $n \in \mathbb{N}_+$ (which evidently implies $n \in \mathbb{N}$) that there exist unique natural numbers $\bar{q}$ and $\bar{r}$ satisfying $\bar{r} < p$ and

$$n = \bar{q}p + \bar{r}. \qquad (5.578)$$

We prove now $\bar{q} \neq 0$ by contradiction, assuming the negation $\neg\bar{q} \neq 0$ to be true, so that the Double Negation Law yields the true sentence $\bar{q} = 0$. We then obtain $\bar{q}p = 0$ according to (5.471) and therefore via substitution $n = 0 + \bar{r}$, resulting evidently in $n = \bar{r}$. With this equation, the previously found $\bar{r} < p$ gives $n < p$, which in turn implies $\neg p \leq n$ with the Negation Formula for $\leq$. This finding clearly contradicts the previously made assumption $p \leq n$, so that the proof of $\bar{q} \neq 0$ is complete. Since $\bar{q}$ is a natural number, this inequality implies $0 < \bar{q}$ with (5.328). We may therefore apply the Monotony Law for $\cdot_{\mathbb{N}}$ and $<_{\mathbb{N}}$ to the initially assumed inequality $1 < p$ in order to obtain $1 \cdot \bar{q} < p \cdot \bar{q}$, which evidently yields

$$\bar{q} < \bar{q} \cdot p. \qquad (5.579)$$

Noting that $\bar{r} \in \mathbb{N}$ implies $0 \leq \bar{r}$ with (4.187), we obtain the inequality

$$\bar{q} \cdot p \leq (\bar{q} \cdot p) + \bar{r}$$

by means of the Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$. In conjunction with (5.579), this gives us now $\bar{q} < (\bar{q} \cdot p) + \bar{r}$ with the Transitivity Formula for $<$ and $\leq$, which we may write also in the form

$$\bar{q} < \bar{q}p + \bar{r},$$

according to (5.521). Combining this inequality with the equation (5.578) via substitution results in $\bar{q} < n$. On the one hand, we observe now that the previous findings $\bar{q} \in \mathbb{N}$ and $\bar{q} \neq 0$ imply $\bar{q} \in \mathbb{N}_+$ with (2.310). On the other hand, we notice that the Law of the Excluded Middle yields the true disjunction $\bar{q} < p \lor \neg \bar{q} < p$, which we use now to establish the uniquely existential sentence

$$\exists! m, c\,(m \in \mathbb{N} \land c : \{1, \ldots, m+1\} \to \mathbb{N} \tag{5.580}$$
$$\land\ \forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow c_i < p) \land c_{m+1} \neq 0 \land \bar{q} = \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}])$$

by cases. Indeed, due to $\bar{q} \in \mathbb{N}_+$, the sentence (5.580) is implied in the first case $\bar{q} < p$ in view of the already proved universal sentence (5.562); in the second case $\neg \bar{q} < p$, which yields $p \leq \bar{q}$ with the Negation Formula for $<$, we obtain (5.580) in view of the induction assumption, recalling the truth of $\bar{q} < n$. Thus, there are unique constants m, c such that m is a natural number and c a function $c : \{1, \ldots, m+1\} \to \mathbb{N}$ satisfying $c_i < p$ for any $i \in \{1, \ldots, m+1\}$, the inequality $c_{m+1} \neq 0$, and moreover the equation

$$\bar{q} = \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}]. \tag{5.581}$$

Here, the sum is evaluated for the function $s : \{1, \ldots, m+1\} \to \mathbb{N}$ with values

$$\forall i\,(i \in \{1, \ldots, m+1\} \Rightarrow s(i) = c_i \cdot p^{i-1}), \tag{5.582}$$

according to Exercise 5.61. We then obtain the true equations

$$n = \bar{q} \cdot p + \bar{r} = \left(\sum_{i=1}^{m+1} [c_i \cdot p^{i-1}] \right) \cdot p + \bar{r} = p \cdot \sum_{i=1}^{m+1} [c_i \cdot p^{i-1}] + \bar{r}$$
$$= \sum_{i=1}^{m+1} (p \cdot [c_i \cdot p^{i-1}]) + \bar{r} \tag{5.583}$$

using (5.578) in connection with (5.521), (5.581), the Commutative Law for the multiplication on $\mathbb{N}$ and the Generalized Distributive Law for semirings.

We use now Function definition by replacement to establish a sequence $d = (d_i \,|\, i \in \{1, \ldots, m+2\})$ whose terms satisfy

$$\forall i\,(i \in \{1, \ldots, m+2\} \tag{5.584}$$
$$\Rightarrow ([i = 1 \Rightarrow d_i = \bar{r}] \land [i \in \{2, \ldots, m+2\} \Rightarrow d_i = c_{i-1}])).$$

This task requires the verification of the universal sentence

$$\forall i\,(i \in \{1, \ldots, m+2\} \tag{5.585}$$
$$\Rightarrow \exists! y\,([i = 1 \Rightarrow y = \bar{r}] \land [i \in \{2, \ldots, m+2\} \Rightarrow y = c_{i-1}])).$$

We let i be arbitrary and assume $i \in \{1, \ldots, m+2\}$ to be true. Now, since $m \in \mathbb{N}$ gives the inequality $0 \leq m$ because of (4.187), we obtain $1 \leq m+1$ with the Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$, where $m+1 < (m+1)+1$ is also true according to (5.217) and (4.153). Evidently, the latter inequality implies $m+1 \leq m+2$ and therefore – in conjunction with $1 \leq m+1$ – also $1 \leq m+2$. Consequently, we obtain

$$\{1\} \cup \{2, \ldots, m+2\} = \{1, \ldots, m+2\} \tag{5.586}$$

with (4.299) and the evident facts $\{1\} = \{1, \ldots, 1\}$ and $1^+ = 2$. Here, we note that

$$\{1\} \cap \{2, \ldots, m+2\} = \emptyset \tag{5.587}$$

holds because of (4.302). The preceding assumption $i \in \{1, \ldots, m+2\}$ implies now in view of the disjunction $i \in \{1\} \vee i \in \{2, \ldots, m+2\}$ by definition of the union of two sets, which allows us to prove the existential part of the uniquely existential sentence in (5.585) by cases. The first case $i \in \{1\}$ yields on the one hand evidently $i = 1$; on the other hand, (5.587) shows in light of the definition of the empty set that $\neg i \in \{1\} \cap \{2, \ldots, m+2\}$ holds. Thus,

$$\neg i \in \{1\} \vee \neg i \in \{2, \ldots, m+2\} \tag{5.588}$$

follows to be true with the definition of the intersection of two sets and De Morgan's Law for the conjunction. Due to the current case assumption, we have that $\neg i \in \{1\}$ is false, so that $\neg i \in \{2, \ldots, m+2\}$ is true. Thus, replacing the variable y by the given constant $\bar{r}$ gives us the true implications

$$[i = 1 \Rightarrow \bar{r} = \bar{r}] \wedge [i \in \{2, \ldots, m+2\} \Rightarrow \bar{r} = c_{i-1}],$$

as the antecedent and the consequent of the first implication are both true and as the antecedent of the second implication is false. In the second case $i \in \{2, \ldots, m+2\}$, we have that the second part of the disjunction (5.588) is now false, with the consequence that $\neg i \in \{1\}$ must be true, which we may write equivalently as $i \neq 1$ by means of (2.169) and the Law of Contraposition. Let us observe that the current case assumption implies $2 \leq i \leq m+2$ with (4.290); due to the evident fact $1 \leq 2$ and the evident consequence $1 \leq i$, we may apply the Monotony Law for $-_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$ to the inequalities $2 \leq i \leq m+2$ to obtain $2-1 \leq i-1 \leq (m+2)-1$. Clearly, we have therefore $1 \leq i-1 \leq m+1$, which shows in light of (4.290) that $i-1 \in \{1, \ldots, m+1\}$ is true, i.e. that $i-1$ is in the index set of the sequence c, so that c_{i-1} constitutes a term of that sequence. Thus, replacing the variable y by the given constant c_{i-1} yields the true implications

$$[i = 1 \Rightarrow c_{i-1} = \bar{r}] \wedge [i \in \{2, \ldots, m+2\} \Rightarrow c_{i-1} = c_{i-1}],$$

the antecedent of the implication being false and the antecedent and consequent of the second implication being true. This finding completes the proof of the existential part by cases, and we proceed in a similar way to establish also the uniqueness part. Letting y and y' be arbitrary and assuming the implications

$$[i = 1 \Rightarrow y = \bar{r}] \wedge [i \in \{2, \ldots, m+2\} \Rightarrow y = c_{i-1}]$$
$$[i = 1 \Rightarrow y' = \bar{r}] \wedge [i \in \{2, \ldots, m+2\} \Rightarrow y' = c_{i-1}]$$

to hold, we obtain in case of $i \in \{1\}$ the equation $i = 1$ and therefore $y = \bar{r} = y'$, and in case of $i \in \{2, \ldots, m+2\}$ the equations $y = c_{i-1} = y'$. Because y and y' are arbitrary, we may now infer from the truth of $y = y'$ (in both cases) the truth of the uniqueness part and thus the truth of the uniquely existential sentence in (5.585). Here, i was arbitrary, so that the universal sentence (5.585) follows now also to be true, and this sentence implies the unique existence of a function d with domain $\{1, \ldots, m+2\}$ such that (5.584). Let us verify that $\mathbb{N}$ is a codomain of d, i.e. that the range of d is included in $\mathbb{N}$. We let for this purpose y be arbitrary, and we assume $y \in \mathrm{ran}(d)$ to be true. Due to the definition of a range, there exists then a constant, say $\bar{k}$, such that $(\bar{k}, y) \in d$ holds, where $\bar{k} \in \{1, \ldots, m+2\}$ is true by definition of a domain. In view of (5.584), we obtain then $d(\bar{k}) = \bar{r}$ in case of $\bar{k} \in \{1\}$, and $d(\bar{k}) = c_{\bar{k}-1}$ in case of $\bar{k} \in \{2, \ldots, m+2\}$. Recalling that $\bar{r}$ is a natural number and noting that the function value $c_{\bar{k}-1}$ is an element of the codomain $\mathbb{N}$ of c, we find $\bar{k} \in \mathbb{N}$ to be true in any case. Writing now $(\bar{k}, y) \in d$ in function notation as $y = d_{\bar{k}}$, we arrive at $y \in \mathbb{N}$ through substitution. We thus showed that $y \in \mathrm{ran}(d)$ implies $y \in \mathbb{N}$, and since y was arbitrary, we may infer from the truth of that implication the truth of the inclusion $\mathrm{ran}(d) \subseteq \mathbb{N}$ (according to the definition of a subset). This shows that $\mathbb{N}$ is a codomain of d, that is, we have $d : \{1, \ldots, m+2\} \to \mathbb{N}$, which we can write also in the form $d : \{1, \ldots, (m+1)+1\} \to \mathbb{N}$. According to Exercise 5.61, this function in turn defines the function $S : \{1, \ldots, (m+1)+1\} \to \mathbb{N}$ whose values satisfy

$$\forall i\, (i \in \{1, \ldots, (m+1)+1\} \Rightarrow S(i) = d_i \cdot p^{i-1}). \tag{5.589}$$

We obtain then the equations

$$\begin{aligned}\sum_{i=1}^{m+2} S_i &= \sum_{i=1}^{1} S_i + \sum_{j=1}^{(m+2)-1} S_{1+j} = \sum_{j=1}^{m+1} S_{1+j} + S_1 \\ &= \sum_{j=1}^{m+1} [d_{1+j} \cdot p^{(1+j)-1}] + [d_1 \cdot p^{1-1}] = \sum_{j=1}^{m+1} [d_{j+1} \cdot p^j] + \bar{r}\end{aligned} \tag{5.590}$$

by using the Generalized Associative Law for semigroups, the commutativity of the addition on $\mathbb{N}$, (5.589), and (5.584) based on the evident facts $1 \in \{1, \ldots, m+2\}$ and $p^{1-1} = p^0 = 1$ in connection with (5.476). Concerning the $(m+1)$-fold sums in the preceding equation and in (5.583), we can now prove that the involved sequences

$$(p \cdot [c_i \cdot p^{i-1}] \,|\, i \in \{1, \ldots, m+1\}), \quad (d_{j+1} \cdot p^j \,|\, i \in \{1, \ldots, m+1\}) \tag{5.591}$$

are identical, so that the evaluation of their sums results in the same value. To do this, we apply the Equality Criterion for functions and let i be an arbitrary element of the joint domain $\{1, \ldots, m+1\}$. Evidently, this implies $1 \leq i \leq m+1$ and then $2 \leq i+1 \leq m+2$, so that $i+1 \in \{2, \ldots, m+2\}$ holds. By definition of the function d, we therefore have $d_{i+1} = c_{(i+1)-1} = c_i$. We then obtain

$$\begin{aligned} d_{i+1} \cdot p^i &= c_i \cdot p^i = c_i \cdot p^{(i-1)+1} = c_i \cdot (p^{i-1} \cdot p^1) = c_i \cdot (p^{i-1} \cdot p) \\ &= p \cdot (c_i \cdot p^{i-1}) \end{aligned}$$

by applying substitution, (5.343), the Addition Rule for powers, (5.477), and the associativity as well as commutativity of the multiplication on $\mathbb{N}$. Since i is arbitrary, we may therefore conclude that the two sequences in (5.591) are indeed identical, so that the associated sums are equal, i.e.

$$\sum_{i=1}^{m+1} (p \cdot [c_i \cdot p^{i-1}]) = \sum_{j=1}^{m+1} [d_{j+1} \cdot p^j],$$

recalling that $\sum_{i=1}^{m+1}$ is a function. Applying now a substitution based on this equation to (5.583) leads with (5.590) and (5.589) to

$$\begin{aligned} n &= \sum_{i=1}^{m+1} (p \cdot [c_i \cdot p^{i-1}]) + \overline{r} = \sum_{j=1}^{m+1} [d_{j+1} \cdot p^j] + \overline{r} = \sum_{i=1}^{m+2} S_i \\ &= \sum_{i=1}^{(m+1)+1} [d_i \cdot p^{i-1}]. \end{aligned} \tag{5.592}$$

Let us observe next that the evident fact $m+2 \in \{2, \ldots, m+2\}$ implies with (5.584) $d_{m+2} = c_{(m+2)-1}$ and therefore evidently $d_{(m+1)+1} = c_{m+1}$. Recalling now the truth of $c_{m+1} \neq \emptyset$, we thus find

$$d_{(m+1)+1} \neq \emptyset. \tag{5.593}$$

Furthermore, we may establish the truth of the universal sentence

$$\forall i \, (i \in \{1, \ldots, (m+1)+1\} \Rightarrow d_i < p), \tag{5.594}$$

letting $j \in \{1, \ldots, (m+1)+1\}$ be arbitrary. In case of $j \in \{1\}$, we obtain $d_j = \bar{r}$ in view of (5.584), where $\bar{r} < p$ is true as mentioned earlier, so that $d_j < p$ follows to be true via substitution. The other case $j \in \{2, \ldots, m+2\}$ yields on the one hand $d_j = c_{j-1}$ again with (5.584), and on the other hand $j-1 \in \{1, \ldots, m+1\}$ (as shown previously). We stated before that $c_i < p$ holds for any $i \in \{1, \ldots, m+1\}$, so that $c_{j-1} < p$ is true in particular. Thus, we find $d_j < p$ also for the second case. Here, j was arbitrary, and therefore the universal sentence (5.594) follows to be true.

We thus found a particular number $m+1 \in \mathbb{N}$ and a particular function $d : \{1, \ldots, (m+1)+1\} \to \mathbb{N}$ satisfying the universal sentence (5.594), the inequality (5.593) and the equation (5.592), so that the proof of the existential part of the uniquely existential sentence in (5.577) is now complete.

To prove the uniqueness part (according to Notation 1.4), we let m', c', m'' and c'' be arbitrary such that m' and m'' are natural numbers, such that c' is a function from $\{1, \ldots, m'+1\}$ to $\mathbb{N}$ and c'' a function from $\{1, \ldots, m''+1\}$ to $\mathbb{N}$, such that $c'_i < p$ holds for all $i \in \{1, \ldots, m'+1\}$ and $c''_i < p$ for all $i \in \{1, \ldots, m''+1\}$, such that c'_{m+1} and c''_{m+1} are different from zero, and such that the equations

$$n = \sum_{i=1}^{m+1} [c'_i \cdot p^{i-1}] \tag{5.595}$$

$$n = \sum_{i=1}^{m'+1} [c''_i \cdot p^{i-1}] \tag{5.596}$$

are satisfied. The task is now to establish $m' = m''$ and of $c' = c''$. To begin with, we observe that $m', m'' \in \mathbb{N}$ implies $0 \leq m'$ as well as $0 \leq m''$, so that the disjunctions $0 < m' \vee 0 = m'$ and $0 < m'' \vee 0 = m''$ are true according to the Characterization of an induced irreflexive partial ordering. Here, we can prove by contradiction that $\neg 0 = m' \wedge \neg 0 = m''$ holds. Assuming the negation of that conjunction to be true, we obtain the true disjunction $m' = 0 \vee m'' = 0$ with De Morgan's Law for the conjunction and the Double Negation Law. Let us use this disjunction to prove $n < p$ by cases. Clearly, (5.595) and (5.596) imply in the first and the second case, respectively,

$$n = \sum_{i=1}^{1} [c'_i \cdot p^{i-1}] = c'_1 \cdot p^{1-1} = c'_1 \cdot p^0 = c'_1$$

$$n = \sum_{i=1}^{1} [c''_i \cdot p^{i-1}] = c''_1 \cdot p^{1-1} = c''_1 \cdot p^0 = c''_1$$

and thus $n < p$ (recalling that $c'_i < p$ and $c''_i < p$ are true for any index).

Consequently, $\neg p \leq n$ follows to be true, in contradiction to the previous assumption $p \leq n$. Having established the truth of $\neg m' = 0$ and $\neg m'' = 0$, we can infer from these negations the truth of the first parts $0 < m'$ and $0 < m''$ of the preceding disjunctions. These inequalities further imply $1 \leq m'$ and $1 \leq m''$ with (4.157), which findings evidently allow us to rewrite (5.595) as

$$\begin{aligned}
n &= \sum_{i=1}^{1}[c'_i \cdot p^{i-1}] + \sum_{j=1}^{(m'+1)-1}[c'_{1+j} \cdot p^{(1+j)-1}] \\
&= \sum_{j=1}^{(m'-1)+1}[c'_{1+j} \cdot p^{(j-1)+1}] + c'_1 \cdot p^{1-1} \\
&= \sum_{j=1}^{(m'-1)+1}[c'_{1+j} \cdot p^{j-1} \cdot p^1] + c'_1 \cdot p^0 \\
&= \sum_{j=1}^{(m'-1)+1}[c'_{1+j} \cdot p^{j-1} \cdot p] + c'_1 \cdot 1 \\
&= p \cdot \sum_{j=1}^{(m'-1)+1}[c'_{1+j} \cdot p^{j-1}] + c'_1 \\
&= \left(\sum_{j=1}^{(m'-1)+1}[c'_{1+j} \cdot p^{j-1}]\right) \cdot p + c'_1,
\end{aligned}$$

and in the same way (5.596) as

$$n = \left(\sum_{j=1}^{(m''-1)+1}[c''_{1+j} \cdot p^{j-1}]\right) \cdot p + c''_1.$$

Recalling now from (5.578) that $\bar{q}$ and $\bar{r}$ are the only constants satisfying $n = \bar{q} \cdot p + \bar{r}$, we obtain according to Notation 1.4

$$\sum_{j=1}^{(m'-1)+1}[c'_{1+j} \cdot p^{j-1}] = \bar{q} = \sum_{j=1}^{(m''-1)+1}[c''_{1+j} \cdot p^{j-1}]$$

and $c'_1 = \bar{r} = c''_1$. Furthermore, we noted after proving (5.580) that there is a unique $m \in \mathbb{N}$ as well as a unique $c : \{1, \ldots, m+1\} \to \mathbb{N}$ satisfying

$\bar{q} = \sum_{i=1}^{m+1}[c_i \cdot p^{i-1}]$ in (5.581), so that we obtain $m' - 1 = m = m'' - 1$ and

$$\begin{aligned}(c'_{1+j} \,|\, j \in \{1, \ldots, (m'-1)+1\}) &= (c_i \,|\, i \in \{1, \ldots, m+1\}) \\ &= (c''_{1+j} \,|\, j \in \{1, \ldots, (m''-1)+1\}).\end{aligned}$$

These equations give us (using also the alternative notation according to the Generalized Associative Law for semigroups)

$$(c'_i \,|\, j \in \{2, \ldots, m'+1\}) = (c''_i \,|\, j \in \{2, \ldots, m'+1\}),$$

and the Equality Criterion for functions yields then

$$\forall i\, (i \in \{2, \ldots, m'+1\} \Rightarrow c'_i = c''_i), \tag{5.597}$$

which allows us to complete the proof of $c' = c''$. To do this, we apply again the Equality Criterion for functions and verify accordingly

$$\forall i\, (i \in \{1, \ldots, m'+1\} \Rightarrow c'_i = c''_i), \tag{5.598}$$

letting $i \in \{1, \ldots, m'+1\}$ be arbitrary. We noted previously that $0 \leq m'$ holds, so that $1 \leq m'+1$ follows to be true with the Monotony Law for $+_{\mathbb{N}}$ and $\leq_{\mathbb{N}}$. Consequently, we have $1 \leq i$ according to (4.276), which gives us evidently the true disjunction $1 < i \lor 1 = i$. In case of $1 < i$, it follows that $2 \leq i$ is true, with the consequence that $i \in \{2, \ldots, m'+1\}$ holds (by definition of an intermediate segment). Thus, we obtain with (5.597) $c'_i = c''_i$, as desired. In the other case of $1 = i$, we recall the previously found $c'_1 = \bar{r} = c''_1$, so that substitution yields again the desired consequent $c'_i = c''_i$. Having completed the proof by cases, we may now infer from this the truth of the universal sentence (5.598), and therefore the truth of $c' = c''$. In conjunction with the previously established $m' = m''$, this allows us to conclude that the uniqueness part of the uniquely existential sentence in (5.577) holds, since m', c', m'' and c'' were arbitrary. We thus completed the proof of that uniquely existential sentence, which in turn completes the proof of the implication based on the antecedent $p \leq n$ in (5.577). As n was initially arbitrary, the proof of (5.576) via strong induction is now complete.

We are now in a position to prove (5.561). For this purpose, we let $n \in \mathbb{N}_+$ be arbitrary and consider the two cases $n < p$ and $\neg n < p$. In the first case $n < p$, the desired uniquely existential sentence in (5.561) follows to be true with (5.562). The second case $\neg n < p$ implies $p \leq n$ with the Negation Formula for $<$, and this inequality implies the desired uniquely existential sentence now with (5.576), completing the proof by cases. Because n was arbitrary, the universal sentence (5.576) follows then to be true, and as p was initially also arbitrary, we may finally conclude that the stated theorem holds. $\square$

5.6.6. Countability of Cartesian products

We begin with the construction of two useful injections.

Lemma 5.149. *It is true that there exists the unique function*

$$g : \mathbb{N}_+ \to \mathbb{N}_+ \times \mathbb{N}_+, \qquad n \mapsto (1, n), \tag{5.599}$$

and this function is an injection.

Proof. We apply Function definition by replacement to establish the unique function g with domain $\mathbb{N}_+$ and values satisfying

$$\forall n \, (n \in \mathbb{N}_+ \Rightarrow g(n) = (1, n)) \tag{5.600}$$

To do this, we prove the universal sentence

$$\forall n \, (n \in \mathbb{N}_+ \Rightarrow \exists! Y \, (Y = (1, n))), \tag{5.601}$$

letting $n \in \mathbb{N}_+$ be arbitrary. Then, $(1, n)$ constitutes the (uniquely specified) ordered pair formed by 1 and n, so that we may infer the truth of the uniquely existential sentence $\exists! Y \, (Y = (1, n))$ by means of (1.109). As n was arbitrary, we may therefore conclude that (5.606) holds, and the truth of this universal sentence implies now the unique existence of a function g with domain $\mathbb{N}_+$ such that (5.605).

Let us now verify that $\mathbb{N}_+ \times \mathbb{N}_+$ is a codomain of g, i.e. that the range of g is included in $\mathbb{N}_+ \times \mathbb{N}_+$. We apply for this purpose the definition of a subset and prove the equivalent universal sentence

$$\forall z \, (z \in \mathrm{ran}(g) \Rightarrow z \in \mathbb{N}_+ \times \mathbb{N}_+), \tag{5.602}$$

letting z be arbitrary and assuming $z \in \mathrm{ran}(g)$ to be true. The definition of a range gives us then a particular constant $\bar{n}$ satisfying $(\bar{n}, z) \in g$, where the definition of a domain shows that $\bar{n} \in \mathbb{N}_+$ [$= \mathrm{dom}(g)$] is true. This finding in turn implies $g(\bar{n}) = (1, \bar{n})$ with (5.605). Here, the evident truth of $1 \in \mathbb{N}_+$ and the truth of $\bar{n} \in \mathbb{N}_+$ yields $[g(\bar{n}) =]$ $(1, \bar{n}) \in \mathbb{N}_+ \times \mathbb{N}_+$ with the definition of the Cartesian product of two sets. Since we may write the previously found $(\bar{n}, z) \in g$ in function notation as $z = g(\bar{n})$, we obtain via substitution $z \in \mathbb{N}_+ \times \mathbb{N}_+$, as desired. Because z is arbitrary, we may now infer from this the truth of the universal sentence (5.608), and consequently the truth of the inclusion $\mathrm{ran}(g) \subseteq \mathbb{N}_+ \times \mathbb{N}_+$, which demonstrates that the latter Cartesian product is indeed a codomain of g.

It now remains for us to prove that g constitutes an injection, i.e. that g has the definite property

$$\forall n, n' \, ([n, n' \in \mathbb{N}_+ \wedge g(n) = g(n')] \Rightarrow n = n'). \tag{5.603}$$

We take arbitrary positive natural numbers n and n' such that the corresponding function values $g(n)$ and $g(n')$ are identical. Since $n, n' \in \mathbb{N}_+$ implies $g(n) = (1, n)$ as well as $g(n') = (1, n')$ by definition of the function g, the preceding assumption of $g(n) = g(n')$ yields $(1, n) = (1, n')$ by means of substitution. We then obtain with the Equality Criterion for ordered pairs especially the desired equation $n = n'$, which proves the implication in (5.609). Here, n and n' were arbitrary, so that the universal sentence (5.609) follows to be true, and this means that g is an injection by definition, i.e. $g : \mathbb{N}_+ \hookrightarrow \mathbb{N}_+ \times \mathbb{N}_+$. We thus completed the proof of the lemma. $\square$

Lemma 5.150. *It is true that there exists the unique function*

$$f : \mathbb{N}_+ \times \mathbb{N}_+ \to \mathbb{N}_+, \qquad (m, n) \mapsto 2^m \cdot 3^n, \tag{5.604}$$

and this function is an injection.

Proof. We define the function by replacement, verifying first

$$\forall x \, (x \in \mathbb{N}_+ \times \mathbb{N}_+ \Rightarrow \exists! y \, (\exists m, n \, (x = (m, n) \, \wedge \, y = 2^m \cdot 3^n))). \tag{5.605}$$

For this purpose, we let $x \in \mathbb{N}_+ \times \mathbb{N}_+$ be arbitrary, so that there exist by definition of the Cartesian product of two sets elements of $\mathbb{N}_+$, say $\bar{m}$ and $\bar{n}$, such that $x = (\bar{m}, \bar{n})$ holds. Since $\bar{m}$ and $\bar{n}$ are evidently natural numbers, the powers $2^{\bar{m}}$ and $3^{\bar{n}}$ are clearly specified natural numbers, and their product $\bar{y} = 2^{\bar{m}} \cdot 3^{\bar{n}}$ is also a natural number. Thus, the existential part is true. Regarding the uniqueness part, we let y and y' be arbitrary such that the existential sentences

$$\exists m, n \, (x = (m, n) \, \wedge \, y = 2^m \cdot 3^n)$$
$$\exists m, n \, (x = (m, n) \, \wedge \, y' = 2^m \cdot 3^n)$$

are both true. This means that there are constants, say $\bar{m}$ and $\bar{n}$, with $x = (\bar{m}, \bar{n})$ and $y = 2^{\bar{m}} \cdot 3^{\bar{n}}$, and there are constants, say $\bar{M}$ and $\bar{N}$, with $x = (\bar{M}, \bar{N})$ and $y' = 2^{\bar{M}} \cdot 3^{\bar{N}}$. Combining the two equations for $\bar{x}$ yields $(\bar{m}, \bar{n}) = (\bar{M}, \bar{N})$ and then $\bar{m} = \bar{M}$ as well as $\bar{n} = \bar{N}$ with the Equality Criterion for ordered pairs. Then, we obtain

$$y' = 2^{\bar{M}} \cdot 3^{\bar{N}} = 2^{\bar{m}} \cdot 3^{\bar{n}} = y$$

via substitution, so that $y = y'$ holds. Since y and y' are arbitrary, we may therefore conclude that the uniqueness part of the uniquely existential sentence to be proven is also true. As x was also arbitrary, we may further conclude that (5.605) holds, which implies the existence of a function f with domain $\mathbb{N}_+ \times \mathbb{N}_+$ such that

$$\forall x\,(x \in \mathbb{N}_+ \times \mathbb{N}_+ \Rightarrow \exists m,n\,(x = (m,n) \,\wedge\, f(x) = 2^m \cdot 3^n). \tag{5.606}$$

It is now a simple task to establish

$$\forall m,n\,((m,n) \in \mathbb{N}_+ \times \mathbb{N}_+ \Rightarrow f((m,n)) = 2^m \cdot 3^n). \tag{5.607}$$

Letting m and n be arbitrary such that $(m,n) \in \mathbb{N}_+ \times \mathbb{N}_+$ holds, it follows with (5.606) that there are constants, say $\bar{m}$ and $\bar{n}$, satisfying $(m,n) = (\bar{m},\bar{n})$ and $f((m,n)) = 2^{\bar{m}} \cdot 3^{\bar{n}}$. As the former equation yields $m = \bar{m}$ and $n = \bar{n}$ with the Equality Criterion for ordered pairs, we obtain via substitutions $f((m,n)) = 2^m \cdot 3^n$, as desired. Since m and n are arbitrary, we may therefore conclude that the universal sentence (5.607) is true. Thus, any ordered pair $(m,n) \in \mathbb{N}_+ \times \mathbb{N}_+$ is mapped to $2^m \cdot 3^n$, as indicated in (5.604).

Next, we prove that $\mathbb{N}_+$ is a codomain of the function f. For this purpose, we verify

$$\forall y\,(y \in \operatorname{ran}(f) \Rightarrow y \in \mathbb{N}_+). \tag{5.608}$$

We let y be arbitrary and assume $y \in \operatorname{ran}(f)$ to be true, so that there exists by definition of a range a constant, say $\bar{x}$, such that $(\bar{x}, y) \in f$, i.e. such that $y = f(\bar{x})$ holds. We also see in light of the definition of a domain that $\bar{x} \in \mathbb{N}_+ \times \mathbb{N}_+$ is true, so that there are because of (5.606) constants, say $\bar{m}$ and $\bar{n}$, satisfying $\bar{x} = (\bar{m},\bar{n})$ and

$$[y =]\; f(\bar{x}) = 2^{\bar{m}} \cdot 3^{\bar{n}}.$$

Furthermore, we obtain via substitution $(\bar{m},\bar{n}) \in \mathbb{N}_+ \times \mathbb{N}_+$, which in turn yields $\bar{m} \in \mathbb{N}_+$ and $\bar{n} \in \mathbb{N}_+$ with the definition of the Cartesian product of two sets; thus, $\bar{m}$ and $\bar{n}$ are clearly natural numbers, so that

$$[y =]\; 2^{\bar{m}} \cdot 3^{\bar{n}} \in \mathbb{N} \tag{5.609}$$

holds (using the fact that the multiplication on $\mathbb{N}$ is a binary operation). Since $2 \neq 0$ and $3 \neq 0$ are evidently also true, we may therefore apply Corollary 5.128 to obtain $2^{\bar{m}} \neq 0$ as well as $3^{\bar{n}} \neq 0$. Consequently, the Criterion for zero-divisor freeness yields

$$[y =]\; 2^{\bar{m}} \cdot 3^{\bar{n}} \neq 0$$

and then $y \notin \{0\}$ with (2.169). In view of (5.609), we thus showed that $y \in \mathbb{N}$ and $y \notin \{0\}$ are both true, so that the desired $y \in \mathbb{N}_+$ follows to be true by definition of the set of positive natural numbers. Because y is arbitrary, we may therefore conclude that (5.608) holds, which universal sentence then implies $\mathrm{ran}(f) \subseteq \mathbb{N}_+$ by definition of a subset. Thus, $\mathbb{N}_+$ is indeed a codomain of f, so that f is a function from $\mathbb{N}_+ \times \mathbb{N}_+$ to $\mathbb{N}_+$, as claimed in (5.604).

It finally remains for us to demonstrate that f is an injection. To do this, we verify

$$\forall x, x' \, ([x, x' \in \mathbb{N}_+ \times \mathbb{N}_+ \,\wedge\, f(x) = f(x')] \Rightarrow x = x'), \tag{5.610}$$

letting x and x' be arbitrary and assuming $x, x' \in \mathbb{N}_+ \times \mathbb{N}_+$ as well as $f(x) = f(x')$ to hold. The former assumption implies (by definition of the Cartesian product of two sets) that there are elements of $\mathbb{N}_+$, say $\bar{m}$ and $\bar{n}$, with $(\bar{m}, \bar{n}) = x$, and that there are elements of $\mathbb{N}_+$, say $\bar{m}'$ and $\bar{n}'$, with $(\bar{m}', \bar{n}') = x'$. Thus, we may write for the function values

$$f(x) = f((\bar{m}, \bar{n})) = 2^{\bar{m}} \cdot 3^{\bar{n}},$$
$$f(x') = f((\bar{m}', \bar{n}')) = 2^{\bar{m}'} \cdot 3^{\bar{n}'},$$

which equations allow us to write the assumed $f(x) = f(x')$ as

$$2^{\bar{m}} \cdot 3^{\bar{n}} = 2^{\bar{m}'} \cdot 3^{\bar{n}'}. \tag{5.611}$$

Since $\bar{m}$, $\bar{n}$, $\bar{m}'$ and $\bar{n}'$ are then evidently also elements of $\mathbb{N}$, we obtain with the connexity of the standard linear ordering $<$ of $\mathbb{N}$ the true multiple disjunction

$$\bar{m} < \bar{m}' \,\vee\, \bar{m}' < \bar{m} \,\vee\, \bar{m} = \bar{m}', \tag{5.612}$$

for which it is now possible to prove via contradictions that the negations of the first two parts are true.

Regarding the first part, we assume the negation of $\neg \bar{m} < \bar{m}'$ to be true, so that the Double negation Law yields the true inequality $\bar{m} < \bar{m}'$. According to Property 7 of an ordered elementary domain and the definition of a difference, we then have $\bar{m}' - \bar{m} \neq 0$, and therefore evidently $\bar{m}' - \bar{m} \in \mathbb{N}_+$. Because of (5.540), there exists then a natural number, say $\bar{q}$, such that

$$2^{\bar{m}' - \bar{m}} = 2\bar{q}. \tag{5.613}$$

Furthermore, we obtain the equations

$$2^{\bar{m}'} = 2^{(\bar{m}' - \bar{m}) + \bar{m}} = 2^{\bar{m}' - \bar{m}} \cdot 2^{\bar{m}} = 2\bar{q} \cdot 2^{\bar{m}}$$

with (5.343), the Addition Rule for powers, and with (5.613). Therefore, the equation (5.611) yields

$$2^{\bar{m}} \cdot 3^{\bar{n}} = (2\bar{q} \cdot 2^{\bar{m}}) \cdot 3^{\bar{n}'} = 2^{\bar{m}} \cdot (2\bar{q} \cdot 3^{\bar{n}'}),$$

where we applied also the commutativity and the associativity of $\cdot_{\mathbb{N}}$. Then, we obtain with the Cancellation Rule for $\cdot_{\mathbb{N}}$ the equation $3^{\bar{n}} = 2\bar{q} \cdot 3^{\bar{n}'}$, which we may evidently write as

$$3^{\bar{n}} = 2(\bar{q} \cdot 3^{\bar{n}'}).$$

Let us observe here that the natural number $3^{\bar{n}}$ is odd according to (5.538), so that substitution based on the preceding equation shows that $2(\bar{q} \cdot 3^{\bar{n}'})$ is odd. Since $\bar{q} \cdot 3^{\bar{n}'}$ is a natural number, we also have that $2(\bar{q} \cdot 3^{\bar{n}'})$ is even, by definition. However, Proposition 5.141 shows that it is false that this number is both odd and even, so that we arrived at a contradiction, completing the proof of $\neg \bar{m} < \bar{m}'$.

Regarding the negation of the second part of the multiple disjunction (5.612), we may evidently apply exactly the same line of arguments as for the proof of the negation of the first part, where we simply exchange $\bar{n}$ and $\bar{n}'$ as well as $\bar{m}$ and $\bar{m}'$. We thus obtain the true negation $\neg \bar{m}' < \bar{m}$, so that the third part $\bar{m} = \bar{m}'$ of the multiple disjunction must be true. Consequently, we may apply substitution to (5.611) and write equivalently $2^{\bar{m}} \cdot 3^{\bar{n}} = 2^{\bar{m}} \cdot 3^{\bar{n}'}$, which in turn implies $3^{\bar{n}} = 3^{\bar{n}'}$ with the Cancellation Law for $\cdot_{\mathbb{N}}$. Now, because $3 \in \mathbb{N}$, $1 <_{\mathbb{N}} 3$ and $\bar{n}, \bar{n}'$ are true, we may apply Proposition 5.147 to the ordered elementary domain $(\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, <_{\mathbb{N}})$ to infer from the preceding equation the truth of $\bar{n} = \bar{n}'$.

We thus showed that $\bar{m} = \bar{m}'$ and $\bar{n} = \bar{n}'$ are both true, so that the Equality Criterion for ordered pairs yields

$$[x =] \quad (\bar{m}, \bar{n}) = (\bar{m}', \bar{n}') \quad [= x'],$$

so that we obtain the desired equation $x = x'$, which proves the implication in (5.610). As x and x' are arbitrary, we may therefore conclude that the universal sentence (5.610) is true, so that f follows to be an injection by definition. □

The existence of injections $g : \mathbb{N}_+ \hookrightarrow \mathbb{N}_+ \times \mathbb{N}_+$ and $f : \mathbb{N}_+ \times \mathbb{N}_+ \hookrightarrow \mathbb{N}_+$ (according to Lemma 5.149 and Lemma 5.150) immediately yields the following results by means of the Cantor-Schröder-Bernstein theorem and the symmetry property (4.665) of equinumerosity.

Corollary 5.151. *It is true that the set $\mathbb{N}_+$ and the Cartesian product $\mathbb{N}_+ \times \mathbb{N}_+$ are equinumerous and vice versa, that is,*

$$\mathbb{N}_+ \sim \mathbb{N}_+ \times \mathbb{N}_+, \tag{5.614}$$

$$\mathbb{N}_+ \times \mathbb{N}_+ \sim \mathbb{N}_+. \tag{5.615}$$

Recalling now the truth of $\mathbb{N} \sim \mathbb{N}_+$ and $\mathbb{N}_+ \sim \mathbb{N}$ in view of (4.661) and (4.667), the transitivity property (4.666) equinumerosity gives us:

Corollary 5.152. *It is true that the set* $\mathbb{N}$ *and the Cartesian product* $\mathbb{N}_+ \times \mathbb{N}_+$ *are equinumerous and vice versa, that is,*

$$\mathbb{N} \sim \mathbb{N}_+ \times \mathbb{N}_+, \tag{5.616}$$

$$\mathbb{N}_+ \times \mathbb{N}_+ \sim \mathbb{N}. \tag{5.617}$$

Note 5.33. Since (5.616) means by definition of equinumerous sets that there exists a bijection from $\mathbb{N}$ to $\mathbb{N}_+ \times \mathbb{N}_+$, it means also that $\mathbb{N}_+ \times \mathbb{N}_+$ is a countably infinite set. Thus, $\mathbb{N}_+ \times \mathbb{N}_+$ is more generally a countable set.

Recalling next that $\mathbb{N}_+ \times \mathbb{N}_+ \sim \mathbb{N} \times \mathbb{N}$ and $\mathbb{N} \times \mathbb{N} \sim \mathbb{N}_+ \times \mathbb{N}_+$ are true as shown by (4.679) – (4.680), further applications of the transitivity of '$\sim$' result in:

Corollary 5.153. *It is true that the set* $\mathbb{N}$ *and the Cartesian product* $\mathbb{N} \times \mathbb{N}$ *are equinumerous and vice versa, that is,*

$$\mathbb{N} \sim \mathbb{N} \times \mathbb{N}, \tag{5.618}$$

$$\mathbb{N} \times \mathbb{N} \sim \mathbb{N}. \tag{5.619}$$

Note 5.34. (5.618) shows in light of the definition of equinumerous sets that there is a bijection $d : \mathbb{N} \rightleftarrows \mathbb{N} \times \mathbb{N}$, which means that $\mathbb{N} \times \mathbb{N}$ constitutes a countably infinite set, and thus a countable set.

Corollary 5.154. *It is true that every countably infinite set is equivalent to the Cartesian product of that set with itself, that is,*

$$\forall A\,(A \text{ is countably infinite } \Rightarrow\ A \sim A \times A). \tag{5.620}$$

Proof. Letting A be an arbitrary countably infinite set, we thus have $\mathbb{N} \sim A$ according to Note 4.25. Due to the Idempotent Law for the conjunction, $\mathbb{N} \sim A \wedge \mathbb{N} \sim A$ is then also true, and this conjunction implies $\mathbb{N}\times\mathbb{N} \sim A\times A$ with (4.675). Because $\mathbb{N} \sim A$ yields $A \sim \mathbb{N}$ with the symmetry property (4.665) and since $\mathbb{N} \sim \mathbb{N} \times \mathbb{N}$ is true according to (5.618), we have the cascade of equivalences

$$A\ \sim\ \mathbb{N}\ \sim\ \mathbb{N} \times \mathbb{N}\ \sim\ A \times A.$$

The property of transitivity (4.666) allows us then to infer from these equivalences first

$$\mathbb{N} \sim A \times A \tag{5.621}$$

and then (using $A \sim \mathbb{N}$) the desired consequent $A \sim A\times A$. As the set A was initially arbitrary, we may therefore conclude that the universal sentence (5.620) holds, as claimed. □

Note 5.35. The equivalence (5.621) shows that the Cartesian product of any countably infinite set with itself is again countably infinite.

Corollary 5.155. *It is true that the Cartesian product of any countable set with itself is countable, that is,*

$$\forall A\,(A \text{ is countable } \Rightarrow\; A \times A \text{ is countable}). \tag{5.622}$$

Proof. We take an arbitrary set A and assume A to be countable, so that A is by definition finite or countably infinite. In case A is finite, the Cartesian product $A \times A$ is evidently finite by virtue of the Finiteness of the Cartesian product of two finite sets; thus, $A \times A$ is countable in the first case. In the other case that A is countably infinite, the Cartesian product $A \times A$ is countably infinite, as mentioned in Note 5.35. Thus, $A \times A$ is countable in any case, and since A was initially arbitrary, we may infer from this the truth of the corollary. □

Exercise 5.62. Show that the Cartesian product of two countably infinite sets A and B is itself countably infinite and moreover equivalent to A, i.e.

$$\forall A, B\,([A \text{ is countably infinite } \wedge\; B \text{ is countably infinite}] \Rightarrow\; A \sim A \times B). \tag{5.623}$$

(Hint: Proceed similarly as in the proof of Corollary 5.154, showing now that

$$\mathbb{N} \sim A \times B \tag{5.624}$$

holds.)

Theorem 5.156 (Countability of the Cartesian product of two countable sets). *It is true that the Cartesian product of two countable sets is itself countable, that is,*

$$\forall A, B\,([A \text{ is countable } \wedge\; B \text{ is countable}] \Rightarrow\; A \times B \text{ is countable}). \tag{5.625}$$

Proof. We take arbitrary sets A and B, and we assume both A and B to be countable. To establish the countability of the Cartesian product of these two sets, we consider the two cases $A = \emptyset \vee B = \emptyset$ and $\neg(A = \emptyset \vee B = \emptyset)$. The first case $A = \emptyset \vee B = \emptyset$ implies $A \times B = \emptyset$ with (3.27), where $\emptyset$ is the natural number 0 in view of (2.49) and therefore a finite set due to (4.464). Consequently, we find by means of substitution that $A \times B$ is finite (in the first case).

The second case $\neg(A = \emptyset \vee B = \emptyset)$ implies on the one hand $A \times B \neq \emptyset$ with (3.27), on the other hand $A \neq \emptyset$ and $B \neq \emptyset$ with De Morgan's Law for the disjunction. Since A and B are countable by assumption, we can apply the Countability Criterion (4.653) to infer from the previous findings that there exist particular surjections $f_A : \mathbb{N} \twoheadrightarrow A$ and $f_B : \mathbb{N} \twoheadrightarrow B$. We now use these functions to define a new function g with domain $\mathbb{N} \times \mathbb{N}$ such that

$$\begin{aligned} &\forall x\,(x \in \mathbb{N} \times \mathbb{N} \\ &\quad \Rightarrow [g(x) \in A \times B \,\wedge\, \exists m,n\,(x = (m,n) \,\wedge\, g(x) = (f_A(m), f_B(n)))]). \end{aligned} \tag{5.626}$$

We accomplish this task by means of Function definition by replacement, by verifying the universal sentence

$$\begin{aligned} &\forall x\,(x \in \mathbb{N} \times \mathbb{N} \\ &\quad \Rightarrow \exists! y\,(y \in A \times B \,\wedge\, \exists m,n\,(x = (m,n) \,\wedge\, y = (f_A(m), f_B(n))))). \end{aligned} \tag{5.627}$$

Letting $x \in \mathbb{N} \times \mathbb{N}$ be arbitrary, we see in light of the definition of the Cartesian product of two sets that there exist particular constants $\bar{m} \in \mathbb{N}$ and $\bar{n} \in \mathbb{N}$ with

$$x = (\bar{m}, \bar{n}). \tag{5.628}$$

These constants are thus elements of the domain of the functions f_A and f_B, so that we obtain the uniquely determined function values

$$f_A(\bar{m}) \in A \,\wedge\, f_B(\bar{n}) \in B \tag{5.629}$$

with the Function Criterion. We may then define the ordered pair

$$\bar{y} = (f_A(\bar{m}), f_B(\bar{n})), \tag{5.630}$$

which equation shows in conjunction with (5.628) that the existential sentence

$$\exists m,n\,(x = (m,n) \,\wedge\, y = (f_A(m), f_B(n))) \tag{5.631}$$

is true. Evidently, (5.629) implies that the ordered pair (5.630) is element of the Cartesian product $A \times B$, that is, $\bar{y} \in A \times B$. The conjunction of this finding and the existential sentence (5.631) implies now that the existential part of the uniquely existential sentence in (5.627) holds.

Concerning the uniqueness part, we let y' and y'' be arbitrary such that $y', y'' \in A \times B$ and the existential sentences

$$\begin{aligned} &\exists m,n\,(x = (m,n) \,\wedge\, y' = (f_A(m), f_B(n))) \\ &\exists m,n\,(x = (m,n) \,\wedge\, y'' = (f_A(m), f_B(n))) \end{aligned}$$

are satisfied. Thus, there are particular constants $\bar{m}'$, $\bar{n}'$, $\bar{m}''$ and $\bar{n}''$ such that the equations

$$\begin{aligned} x &= (\bar{m}', \bar{n}') \\ &= (\bar{m}'', \bar{n}'') \end{aligned}$$

and

$$y' = (f_A(\bar{m}'), f_B(\bar{n}'))$$
$$y'' = (f_A(\bar{m}''), f_B(\bar{n}''))$$

are true. On the one hand, the two equations for x imply $(\bar{m}', \bar{n}') = (\bar{m}'', \bar{n}'')$, which equations yields with the Equality Criterion for ordered pairs $\bar{m}' = \bar{m}''$ and $\bar{n}' = \bar{n}''$. On the other hand, the two equations for y' and y'' gives us then through substitutions

$$y' = (f_A(\bar{m}'), f_B(\bar{n}')) = (f_A(\bar{m}''), f_B(\bar{n}'')) = y''.$$

Since y' and y'' are arbitrary, we can infer from the resulting equation $y' = y''$ the truth also of the uniqueness part of the uniquely existential sentence in (5.627). Because x was also arbitrary, the universal sentence (5.627) follows then to be true as well. Consequently, there exists indeed a unique function g with domain $\mathbb{N} \times \mathbb{N}$ whose values are defined by (5.626).

Next, let us apply the Equality Criterion for sets to prove that $A \times B$ is the range of the function g, that is,

$$\forall y\,(y \in \mathrm{ran}(g) \Leftrightarrow y \in A \times B). \tag{5.632}$$

Letting y be arbitrary and assuming first $y \in \mathrm{ran}(g)$ to be true, we have then by definition of a range $(\bar{x}, y) \in g$ for some particular constant $\bar{x}$, which is in $\mathbb{N} \times \mathbb{N}$ by definition of a domain. Therefore, the definition of the function g in (5.626) yields especially $g(\bar{x}) \in A \times B$. Observing that $(\bar{x}, y) \in g$ can be written in function function as $y = g(\bar{x})$, we thus find $y \in A \times B$ to be true via substitution, so that the first part ('$\Rightarrow$') of the equivalence in (5.632) holds.

Concerning the second part ('$\Leftarrow$'), we assume now $y \in A \times B$ to be true. This assumption implies with the definition of the Cartesian product of two sets that there exist particular constants $\bar{a} \in A$ and $\bar{b} \in B$ such that $y = (\bar{a}, \bar{b})$. Recalling the surjectivity of f_A and f_B, we obtain then with the Surjection Criterion also particular constants $\bar{x}_1$ and $\bar{x}_2$ satisfying $f_A(\bar{x}_1) = \bar{a}$ and $f_B(\bar{x}_2) = \bar{b}$. These equations show clearly that $\bar{x}_1$ and $\bar{x}_2$ are in the domain $\mathbb{N}$ of the functions f_A and f_B, with the consequence that the ordered pair $(\bar{x}_1, \bar{x}_2)$ is in the domain $\mathbb{N} \times \mathbb{N}$ of the function g. Therefore, the definition of g gives rise to the existence of particular constants $\bar{m}, \bar{n}$ satisfying the conjunction of $(\bar{x}_1, \bar{x}_2) = (\bar{m}, \bar{n})$ and and $g((\bar{x}_1, \bar{x}_2)) = (f_A(\bar{m}), f_B(\bar{n}))$. The former equation yields with the Equality Criterion for ordered pairs $\bar{x}_1 = \bar{m}$ and $\bar{x}_2 = \bar{n}$, so that the latter equation becomes after substitutions

$$g((\bar{x}_1, \bar{x}_2)) = (f_A(\bar{x}_1), f_B(\bar{x}_2)) = (\bar{a}, \bar{b}) = y.$$

Writing the resulting equation $y = g((\bar{x}_1, \bar{x}_2))$ in the form $((\bar{x}_1, \bar{x}_2), y) \in g$, we now see clearly that y is in the range of g, completing the proof of the implication '$\Leftarrow$' in (5.632).

Since y is arbitrary, we may therefore conclude that the universal sentence (5.632) is true, which then further implies the truth of the equality $\mathrm{ran}(g) = A \times B$. Consequently, the function $g : \mathbb{N} \times \mathbb{N} \to A \times B$ is a surjection. Due to the equivalence $\mathbb{N} \sim \mathbb{N} \times \mathbb{N}$ in (5.618), there exists a bijection from $\mathbb{N}$ to $\mathbb{N} \times \mathbb{N}$, say $\bar{h}$, which thus constitutes in particular a surjection. Then, $g \circ \bar{h}$ is a surjection from $\mathbb{N}$ to $A \times B$ according to the Surjectivity of the composition of two surjections. Recalling here the truth of $A \times B \neq \emptyset$, we see in light of the existence of a surjection from $\mathbb{N}$ to $A \times B$ and in light of the Countability Criterion (4.653) that the Cartesian product $A \times B$ is countable.

We thus completed the proof by cases, and as the sets A and B were initially arbitrary, we may finally conclude that the stated theorem is indeed true. □

Theorem 5.157 (Countability of the union of a countable system of countable sets). *It is true that the union of any countable system of countable sets constitutes a countable set, that is,*

$$\forall \mathcal{S}\,([\mathcal{S} \text{ is countable } \land\ \forall A\,(A \in \mathcal{S} \Rightarrow A \text{ is countable})] \Rightarrow \bigcup \mathcal{S} \text{ is countable}). \tag{5.633}$$

Proof. We establish first the universal sentence

$$\begin{aligned}&\forall \mathcal{S}\,([\mathcal{S} \text{ is countable } \land\ \emptyset \notin \mathcal{S}\ \land\ \forall A\,(A \in \mathcal{S} \Rightarrow A \text{ is countable})]\\ &\quad \Rightarrow \bigcup \mathcal{S} \text{ is countable}),\end{aligned} \tag{5.634}$$

letting $\mathcal{S}$ be an arbitrary set (system). Noting that the Law of the Excluded Middle gives rise to the true disjunction $\mathcal{S} = \emptyset \lor \mathcal{S} \neq \emptyset$, we prove now the implication by cases. In the first case, we assume both the antecedent and $\mathcal{S} = \emptyset$ to be true, which equation yields

$$\bigcup \mathcal{S} = \bigcup \emptyset = \emptyset = 0$$

by means of substitution, (2.205) and (2.49). Recalling that every natural number is a finite set (see Corollary 4.98), we have that $\bigcup \mathcal{S}$ is finite set in the first case.

In the second case, we assume that $\mathcal{S}$ is a nonempty countable set that does not contain the empty set, whose elements are all countable sets. Due to the Countability Criterion (4.653), there exists then a surjection from

$\mathbb{N}$ to $\mathcal{S}$, say $\bar{f} : \mathbb{N} \twoheadrightarrow \mathcal{S}$. Thus, the system $\mathcal{S}$ constitutes the range of $\bar{f}$, that is, $\mathcal{S} = \mathrm{ran}(\bar{f})$, where $\bar{f}$ can in view of its domain be written as the sequence $\bar{f} = (\bar{A}_n)_{n\in\mathbb{N}}$. According to the Function Criterion, every element n in the domain $\mathbb{N}$ of $\bar{f}$ is then associated with the unique value/term A_n in the codomain/range $\mathcal{S}$ of $\bar{f}$, i.e. we have

$$\forall n\,(n \in \mathbb{N} \Rightarrow A_n \in \mathcal{S}). \tag{5.635}$$

Consequently, we have

$$\forall n\,(n \in \mathbb{N} \Rightarrow A_n \text{ is countable}), \tag{5.636}$$

noting that any $n \in \mathbb{N}$ gives with (5.635) the element A_n in $\mathcal{S}$, which is countable by assumption. The preceding assumptions allow us also to choose for each of the countable sets in $\mathcal{S}$ a surjection from $\mathbb{N}$ to that set. To begin with, let us observe that the assumed $\emptyset \notin \mathcal{S}$ implies the universal sentence

$$\forall A\,(A \in \mathcal{S} \Rightarrow A \neq \emptyset) \tag{5.637}$$

with (2.5). This allows us to establish

$$\forall n\,(n \in \mathbb{N} \Rightarrow A_n \neq \emptyset), \tag{5.638}$$

because every $n \in \mathbb{N}$ gives us $A_n \in \mathcal{S}$ with (5.635) and then $A_n \neq \emptyset$ with (5.636). Moreover, we obtain now

$$\forall n\,(n \in \mathbb{N} \Rightarrow \exists g\,(g : \mathbb{N} \twoheadrightarrow A_n)), \tag{5.639}$$

since the assumption $n \in \mathbb{N}$ (for any arbitrary n) implies on the one hand with (5.636) that A_n is countable, and on the other hand with (5.638) that $A \neq \emptyset$ holds, so that the existential sentence in (5.639) follows to be true with the Countability Criterion (4.653). Based on these representation, we collect now for any index $n \in \mathbb{N}$ the surjections from $\mathbb{N}$ to A_n. For this purpose, we prove

$$\forall n\,(n \in \mathbb{N} \Rightarrow \exists! \mathcal{Y}\,\forall g\,(g \in \mathcal{Y} \Leftrightarrow [g \in A_n^{\mathbb{N}} \wedge g : \mathbb{N} \twoheadrightarrow A_n])), \tag{5.640}$$

letting $n \in \mathbb{N}$ be arbitrary and observing the truth of the uniquely existential sentence in light of the Axiom of Specification and the Equality Criterion for sets. According to Function definition by replacement, there exists then a unique function G with domain $\mathbb{N}$, in other words a unique sequence $(G_n)_{n\in\mathbb{N}}$, such that

$$\forall n\,(n \in \mathbb{N} \Rightarrow \forall g\,(g \in G(n) \Leftrightarrow [g \in A_n^{\mathbb{N}} \wedge g : \mathbb{N} \twoheadrightarrow A_n])). \tag{5.641}$$

Here, we can show that the empty set is not an element of the range of G, that is, $\emptyset \notin \mathrm{ran}(G)$. To do this, we apply once again (2.5) and demonstrate the truth of the equivalent universal sentence

$$\forall \mathcal{Y}\,(\mathcal{Y} \in \mathrm{ran}(G) \Rightarrow \mathcal{Y} \neq \emptyset). \tag{5.642}$$

We let $\mathcal{Y}$ be arbitrary and assume $\mathcal{Y} \in \mathrm{ran}(G)$ to be true, so that there exists by definition of a range a constant, say $\bar{n}$, satisfying $(\bar{n}, \mathcal{Y}) \in G$. Then, the definition of a domain yields $\bar{n} \in \mathbb{N}$ $[= \mathrm{dom}(G)]$, which in turn implies with (5.639) that there exists a constant, say $\bar{g}$, such that $\bar{g} : \mathbb{N} \twoheadrightarrow A_{\bar{n}}$. As a function from $\mathbb{N}$ to $A_{\bar{n}}$, $\bar{g}$ is then an element of the set of functions $A_{\bar{n}}^{\mathbb{N}}$, so that the surjection $\bar{g} : \mathbb{N} \twoheadrightarrow A_{\bar{n}}$ turns out to be an element of $G(\bar{n})$ because of (5.641). Noting that we can write the previous finding $(\bar{n}, \mathcal{Y}) \in G$ in function/sequence notation as $\mathcal{Y} = G_{\bar{n}}$, we obtain from $\bar{g} \in G(\bar{n})$ via substitution $\bar{g} \in \mathcal{Y}$, which shows clearly that $\mathcal{Y}$ is nonempty. Thus, the implication in (5.642) is true, in which $\mathcal{Y}$ is arbitrary, so that the universal sentence (5.642) follows to be true. Then, the equivalent negation $\emptyset \notin \mathrm{ran}(G)$ is also true, which allows us to apply the Axiom of Choice to establish the existence of a function, say $\bar{F} : \mathrm{ran}(G) \to \bigcup \mathrm{ran}(G)$, such that

$$\forall \mathcal{Y}\,(\mathcal{Y} \in \mathrm{ran}(G) \Rightarrow \bar{F}(\mathcal{Y}) \in \mathcal{Y})) \tag{5.643}$$

Since the sequence $(G_n)_{n \in \mathbb{N}}$ is evidently a function $G : \mathbb{N} \to \mathrm{ran}(G)$, we obtain the composition $\bar{F} \circ G : \mathbb{N} \to \bigcup \mathrm{ran}(G)$ with Proposition 3.178. Thus, $\bar{F} \circ G$ can be written as the sequence $(\bar{g}_n)_{n \in \mathbb{N}}$. To bring out more clearly the structure of this sequence, we demonstrate that each term $\bar{g}_n$ is a (chosen) surjection from $\mathbb{N}$ to A_n, that is,

$$\forall n\,(n \in \mathbb{N} \Rightarrow \bar{g}_n : \mathbb{N} \twoheadrightarrow A_n). \tag{5.644}$$

Letting $n \in \mathbb{N}$ be arbitrary, we have for the corresponding term $\bar{g}_n = (\bar{F} \circ G)(n) = \bar{F}(G(n))$ (using the notation for compositions), where $G(n)$ is evidently in the range of G, so that (5.643) gives $[\bar{g}_n =]$ $\bar{F}(G(n)) \in G(n)$. The resulting, $\bar{g}_n \in G(n)$ implies now especially $\bar{g}_n : \mathbb{N} \twoheadrightarrow A_n$ with (5.641), which is the desired consequent of the implication to be proven. Since n was arbitrary, we may therefore conclude that (5.644) is indeed true.

Our next task is to establish another function h with domain $\mathbb{N} \times \mathbb{N}$ whose values are defined by

$$\forall z\,(z \in \mathbb{N} \times \mathbb{N} \Rightarrow \exists m, n\,(h(z) \in \bigcup \mathcal{S} \,\wedge\, z = (m, n) \,\wedge\, h(z) = \bar{g}_m(n))). \tag{5.645}$$

We can accomplish this task through Function definition by replacement, by proving

$$\forall z\,(z \in \mathbb{N} \times \mathbb{N} \Rightarrow \exists! y\,(\exists m, n\,(y \in \bigcup \mathcal{S} \wedge z = (m, n) \wedge y = \bar{g}_m(n)))). \tag{5.646}$$

We take an arbitrary element $z \in \mathbb{N} \times \mathbb{N}$, so that there exist by definition of the Cartesian product of two sets particular elements $\bar{m} \in \mathbb{N}$ and $\bar{n} \in \mathbb{N}$ for which $(\bar{m}, \bar{n}) = z$ holds. Thus, the natural number $\bar{m}$ is associated with the term $\bar{g}_{\bar{m}}$ of the sequence $(\bar{g}_n)_{n \in \mathbb{N}}$, which term constitutes a surjection $\bar{g}_{\bar{m}} : \mathbb{N} \twoheadrightarrow A_{\bar{m}}$, as shown by (5.644). Then, the natural number $\bar{n}$ is associated with the value $\bar{y} = \bar{g}_{\bar{m}}(\bar{n})$ in the codomain/range $A_{\bar{m}}$ of that surjection. Because of $\bar{m} \in \mathbb{N}$, we obtain furthermore $A_{\bar{m}} \in \mathcal{S}$ with (5.635), which implies in conjunction with the preceding finding $\bar{y} \in A_{\bar{m}}$ that $\bar{y}$ is an element of the union of the set system $\mathcal{S}$. Having thus established the truth of $\bar{y} \in \bigcup \mathcal{S}$, of $z = (\bar{m}, \bar{n})$ and of $\bar{y} = \bar{g}_{\bar{m}}(\bar{n})$, we now see that the existential part of the uniquely existential sentence in (5.646) holds.

Having already found a particular constant $\bar{y}$ for which the existential sentence with respect to m and n holds, we may prove the uniqueness part by means of Method 1.18. For this purpose, we let y' be arbitrary, assume the existence of particular constants m', n' satisfying $y' \in \bigcup \mathcal{S}$, $z = (m', n')$ and $y' = \bar{g}_{m'}(n')$, and show that $\bar{y} = y'$ is implied. Combining the equations $z = (m', n')$ and $z = (\bar{m}, \bar{n})$ yields $(m', n') = (\bar{m}, \bar{n})$, and the Equality Criterion for ordered pairs gives us therefore $m' = \bar{m}$ as well as $n' = \bar{n}$. Applying now substitutions based on these equations, we obtain

$$y' = \bar{g}_{m'}(n') = \bar{g}_{\bar{m}}(\bar{n}) = \bar{y},$$

resulting in the desired consequent $\bar{y} = y'$. As y' was arbitrary, we may infer from this equation the truth of the uniqueness part and thus the truth of the uniquely existential sentence in (5.646). Because z was arbitrary, we may further conclude that the universal sentence (5.646) holds, so that there exists indeed a unique function h with domain $\mathbb{N} \times \mathbb{N}$ such that (5.645).

Let us check that $\mathcal{S}$ is a codomain of that function, i.e. that the range of h is included in $\bigcup \mathcal{S}$. To do this, we apply the definition of a subset and take accordingly an arbitrary constant y, assuming $y \in \operatorname{ran}(h)$ to be true. Then, the definition of a range gives us a particular constant $\bar{z}$ such that $(\bar{z}, y) \in h$ is true, which we may write in function notation as $y = h(\bar{z})$. Recalling that $\mathbb{N} \times \mathbb{N}$ is the domain of h, we also see that $\bar{z} \in \mathbb{N} \times \mathbb{N}$ holds. Consequently, (5.645) gives us $[y =]\ h(\bar{z}) \in \bigcup \mathcal{S}$. We thus proved that $y \in \operatorname{ran}(h)$ implies $y \in \bigcup \mathcal{S}$, and since y is arbitrary, we may infer from the truth of this implication the truth of the suggested inclusion $\operatorname{ran}(h) \subseteq \bigcup \mathcal{S}$. This demonstrates that h is a function from $\mathbb{N} \times \mathbb{N}$ to the union $\bigcup \mathcal{S}$.

In the next step, we prove conversely that the union $\bigcup \mathcal{S}$ is included in the range of h, letting y be arbitrary and assuming $y \in \bigcup \mathcal{S}$ to hold. By definition of the union of a set system, there exists then a set, say $\bar{X}$, for which $\bar{X} \in \mathcal{S}$ and $y \in \bar{X}$ both hold. Recalling the truth of the equation $\mathcal{S} = \operatorname{ran}(\bar{f})$, it follows with the definition of a range that there exists a constant, say $\bar{m}$, such that $(\bar{m}, \bar{X}) \in \bar{f}$ is true. Since $\bar{f}$ is the sequence $(\bar{A}_n)_{n\in\mathbb{N}}$, we obtain with the definition of a domain $\bar{m} \in \mathbb{N}$, and we can write for the corresponding term $\bar{X} = \bar{f}_{\bar{m}} = \bar{A}_{\bar{m}}$. Thus, $y \in \bar{X}$ implies $y \in \bar{A}_{\bar{m}}$ by means of substitution. In addition, $\bar{m} \in \mathbb{N}$ gives rise to the surjection $\bar{g}_{\bar{m}} : \mathbb{N} \twoheadrightarrow A_{\bar{m}}$ due to (5.644), so that y is in the range of $\bar{g}_{\bar{m}}$. Consequently, there exists a particular constant, say $\bar{n}$, satisfying $(\bar{n}, y) \in \bar{g}_{\bar{m}}$, which finding we can write in the form $y = \bar{g}_{\bar{m}}(\bar{n})$. Defining now the ordered pair $\bar{z} = (\bar{m}, \bar{n})$, we see in light of $y \in \bigcup \mathcal{S}$ and the preceding equations for z and y that the existential sentence

$$\exists m, n\,(y \in \bigcup \mathcal{S} \wedge \bar{z} = (m,n) \wedge y = \bar{g}_m(n)) \tag{5.647}$$

is true. Noting that $(\bar{n}, y) \in \bar{g}_{\bar{m}}$ yields $\bar{n} \in \mathbb{N}$ [$= \mathrm{dom}(\bar{g}_{\bar{m}})$] by definition of a domain, so that both $\bar{m}$ and $\bar{n}$ are natural numbers, we have that the ordered pair $\bar{z}$ is element of the Cartesian product $\mathbb{N} \times \mathbb{N}$. This fact implies with (5.645) that the corresponding function value $h(\bar{z})$ satisfies

$$\exists m, n\,(h(\bar{z}) \in \bigcup \mathcal{S} \wedge \bar{z} = (m,n) \wedge h(\bar{z}) = \bar{g}_m(n)). \tag{5.648}$$

Then, in view of the uniquely existential sentence in (5.646), we obtain the equation $y = h(\bar{z})$, which we can write also in the form $(\bar{z}, y) \in h$. Thus, y is an element of the range of h, so that the proof of the implication $y \in \bigcup \mathcal{S} \Rightarrow y \in \mathrm{ran}(h)$ is complete. Because y was arbitrary, we may therefore conclude (by definition of a subset) that the inclusion $\bigcup \mathcal{S} \subseteq \mathrm{ran}(h)$ holds.

Having thus established the truth of the two inclusions $\mathrm{ran}(h) \subseteq \bigcup \mathcal{S}$ and $\bigcup \mathcal{S} \subseteq \mathrm{ran}(h)$, we can use the Axiom of Extension to infer the truth of the equality $\mathrm{ran}(h) = \bigcup \mathcal{S}$. This shows that h is a surjection from $\mathbb{N} \times \mathbb{N}$ to $\bigcup \mathcal{S}$. As $\mathbb{N}$ and the preceding Cartesian product $\mathbb{N} \times \mathbb{N}$ are equinumerous, as shown by (5.618), there exists a bijection from $\mathbb{N}$ to $\mathbb{N} \times \mathbb{N}$, say $\bar{b}$. This bijection is by definition a surjection, that is, $\bar{b} : \mathbb{N} \twoheadrightarrow \mathbb{N} \times \mathbb{N}$, so that the composition $h \circ \bar{b}$ constitutes a surjection from $\mathbb{N}$ to $\bigcup \mathcal{S}$, according to (3.649). We thus proved the existential sentence $\exists f\,(f : \mathbb{N} \twoheadrightarrow \bigcup \mathcal{S})$, which evidently implies with the Countability Criterion (4.653) that $\bigcup \mathcal{S}$ is a countable set.

This finding completes the proof of the implication in (5.634) by cases. Since $\mathcal{S}$ was initially arbitrary, we may therefore conclude that the universal sentence (5.634) holds.

We are now in a position to prove the proposed universal sentence (5.633), letting $\mathcal{S}$ be an arbitrary set (system) and considering the two cases $\emptyset \in \mathcal{S}$ and $\emptyset \notin \mathcal{S}$. In the first case, we assume $\mathcal{S}$ to be a countable set such that

$$\forall A\,(A \in \mathcal{S} \Rightarrow A \text{ is countable}). \tag{5.649}$$

and $\emptyset \in \mathcal{S}$ hold. We form then the singleton $\{\emptyset\}$ and observe in light of (4.656) that the set difference $\mathcal{S} \setminus \{\emptyset\}$ (being a subset of $\mathcal{S}$) is then also a countable set, for which

$$\emptyset \notin \mathcal{S} \setminus \{\emptyset\} \tag{5.650}$$

is true according to (2.179). The preceding inclusion allows us to establish

$$\forall A\,(A \in \mathcal{S} \setminus \{\emptyset\} \Rightarrow A \text{ is countable}).$$

Indeed, letting A be arbitrary and assuming $A \in \mathcal{S} \setminus \{\emptyset\}$ to be true, the definition of a subset yields $A \in \mathcal{S}$, which in turn implies with the assumed (5.649) that A is countable. Since A is arbitrary, the preceding universal sentence follows therefore to be true. In conjunction with the countability of $\mathcal{S} \setminus \{\emptyset\}$ and with (5.650), this implies with (5.634) that $\bigcup(\mathcal{S} \setminus \{\emptyset\})$ is a countable set. Since this union is identical with the union $\bigcup \mathcal{S}$ according to (2.203), it follows by means of substitution that the latter constitutes a countable set.

In the second case, we assume that $\mathcal{S}$ is a countable set satisfying (5.649) and $\emptyset \notin \mathcal{S}$. Thus, the union $\bigcup \mathcal{S}$ follows immediately to be true with (5.634). Because $\mathcal{S}$ was arbitrary, we can now infer from these findings the truth of the stated theorem. □

Exercise 5.63. Show that the union of any family having a countable index set and countable terms is itself countable, that is,

$$\begin{aligned}&\forall I, f\,([I \text{ is countable } \wedge\ f = (A_i)_{i \in I}\ \wedge\ \forall i\,(i \in I \Rightarrow A_i \text{ is countable})]\\ &\quad \Rightarrow \bigcup_{i \in I} A_i \text{ is countable}).\end{aligned} \tag{5.651}$$

(Hint: Use Proposition 4.141 and Theorem 5.157.)

Corollary 5.158. *It is true that the union of any countably infinite system of countably infinite sets constitutes a countably infinite set, that is,*

$$\begin{aligned}&\forall \mathcal{S}\,([\mathcal{S} \text{ is countably infinite } \wedge\ \forall A\,(A \in \mathcal{S} \Rightarrow A \text{ is countably infinite})]\\ &\quad \Rightarrow \bigcup \mathcal{S} \text{ is countably infinite}).\end{aligned} \tag{5.652}$$

Proof. We let $\mathcal{S}$ be an arbitrary set (system), assuming that $\mathcal{S}$ is a countably infinite set whose elements are all countably infinite sets. Thus, $\mathcal{S}$ is a countable set whose elements are countable, so that the union $\bigcup \mathcal{S}$ follows to be countable with Theorem 5.157. According to the Countability Criterion (4.652), there exists then an injection $g : \bigcup \mathcal{S} \hookrightarrow \mathbb{N}$.

In addition, the assumption that $\mathcal{S}$ is a countably infinite implies the existence of a particular bijective sequence $A : \mathbb{N} \rightleftarrows \mathcal{S}$, for which $A_1 \in \mathcal{S}$

holds in particular according to the Function Criterion. Since we assumed all elements of $\mathcal{S}$ to be countably infinite, there is then also a particular bijection $\bar{f} : \mathbb{N} \rightleftarrows A_1$. Thus, $\bar{f}$ is an injection $\bar{f} : \mathbb{N} \hookrightarrow A_1$, where $A_1 \in \mathcal{S}$ implies the inclusion $A_1 \subseteq \bigcup \mathcal{S}$ because of (2.201), so that we obtain $\bar{f}$ constitutes the injection $\bar{f} : \mathbb{N} \hookrightarrow \bigcup \mathcal{S}$ due to (3.623). This demonstrates the existence of an injection $f : \mathbb{N} \hookrightarrow \bigcup \mathcal{S}$.

The existence of injections $f : \mathbb{N} \hookrightarrow \bigcup \mathcal{S}$ and $g : \bigcup \mathcal{S} \hookrightarrow \mathbb{N}$ implies then with the Cantor-Schröder-Bernstein theorem that $\mathbb{N}$ and $\bigcup \mathcal{S}$ are equinumerous, that is, $\mathbb{N} \sim \bigcup \mathcal{S}$. This means that there exists a bijection from $\mathbb{N}$ to the union $\bigcup \mathcal{S}$, so that $\bigcup \mathcal{S}$ is countably infinite. As the set $\mathcal{S}$ was initially arbitrary, we may therefore conclude that the stated universal sentence is true. □

Exercise 5.64. Show that the union of any family having a countable, nonempty index set and countably infinite terms is itself countably infinite, that is,

$$\forall I, f\,([I \text{ is countable } \wedge\ I \neq \emptyset\ \wedge\ f = (A_i)_{i \in I} \tag{5.653}$$
$$\wedge\ \forall i\,(i \in I \Rightarrow A_i \text{ is countably infinite})] \Rightarrow \bigcup_{i \in I} A_i \text{ is countably infinite}).$$

(Hint: Proceed similarly as in the proof of Corollary 5.158, using here (5.651) and (2.42).)

Theorem 5.159 (Countability of Cartesian powers $\mathbb{N}^n$). *It is true*

a) *for any $n \in \mathbb{N}$ that $\mathbb{N}^n$ is countable.*

b) *for any $n \in \mathbb{N}_+$ that $\mathbb{N}^n$ is countably infinite.*

Proof. Let us begin with the observation that $\mathbb{N}^0$ denotes the Cartesian product of a constant sequence on $\{1, \ldots, 0\} = \emptyset$, i.e. of a family of sets with empty index set. It therefore follows with (3.863) that the Cartesian product $\mathbb{N}^0$ constitutes the singleton $\{\emptyset\}$, which is a finite set according to (4.470), and thus a countable set by definition.

Next, we verify that $\mathbb{N}^n$ is countably infinite for any positive natural number n, proving the universal sentence

$$\forall n\,(n \in \mathbb{N}_+ \Rightarrow \exists d\,(d : \mathbb{N} \rightleftarrows \mathbb{N}^n)) \tag{5.654}$$

by means of mathematical induction. In the base case ($n = 1$), we apply Function definition by replacement to establish a function $\bar{d}$ with domain $\mathbb{N}$ such that

$$\forall m\,(m \in \mathbb{N} \Rightarrow [\bar{d}(m) \in \mathbb{N}^1\ \wedge\ [\bar{d}(m)](1) = m]). \tag{5.655}$$

For this purpose, we prove the universal sentence

$$\forall m\,(m \in \mathbb{N} \Rightarrow \exists! f\,(f \in \mathbb{N}^1 \,\wedge\, f(1) = m)), \tag{5.656}$$

letting $m \in \mathbb{N}$ be arbitrary. Observing that the Cartesian power $\mathbb{N}^1$ denotes the Cartesian product $\bigtimes_{i=1}^{1} \mathbb{N}$, we demonstrate now that the singleton $\bar{f} = \{(1, m)\}$ is an element of that Cartesian power. On the one hand, since the singleton $\{(1, m)\}$ constitutes a function from $\{1\}$ to $\{m\}$ according to Corollary 3.156, we may view it as a family with index set $\{1\} = \{1, \ldots, 1\}$ (recalling the notation for initial segments of $\mathbb{N}_+$). On the other hand, we may establish the universal sentence

$$\forall i\,(i \in \{1\} \Rightarrow \bar{f}(i) \in \mathbb{N}) \tag{5.657}$$

letting $i \in \{1\}$ be arbitrary gives $i = 1$ with (2.169) and therefore the unique value $\bar{f}(i) = \bar{f}(1)$ in $\{m\}$, so that another application of (2.169) gives $\bar{f}(i) = \bar{f}(1) = m$. Furthermore, in view of the assumed $m \in \mathbb{N}$, the preceding equations give $f(i) \in \mathbb{N}$, proving the implication in (5.657). Since i was arbitrary, we may now infer from this the truth of the universal sentence (5.657), which implies – in conjunction with the fact that $\bar{f} = \{(1, m)\}$ is a family with index set $\{1, \ldots, 1\}$ – that $\bar{f} \in \bigtimes_{i=1}^{1} \mathbb{N}$ is indeed true (by definition of the Cartesian product of a family of sets). Thus, we found $\bar{f} \in \mathbb{N}^1$ and $\bar{f}(1) = m$, so that the existential part of the uniquely existential sentence in (5.656) holds.

Regarding the uniqueness part, we let f and f' be arbitrary, assume $f \in \mathbb{N}^1$, $f(1) = m$, $f' \in \mathbb{N}^1$ and $f'(1) = m$ to be true, and show that $f = f'$ is implied. We prove this equation by means of the Equality Criterion for functions, noting that f and f', as elements of the Cartesian product $\mathbb{N}^1 = \bigtimes_{i=1}^{1} \mathbb{N}$, are families with common index set $\{1, \ldots, 1\}$, and constitute thus functions with common domain $\{1\}$. We therefore demonstrate the truth of the universal sentence

$$\forall i\,(i \in \{1\} \Rightarrow f(i) = f'(i)). \tag{5.658}$$

Letting $i \in \{1\}$ be arbitrary, we obtain $i = 1$ with (2.169) and therefore via substitutions

$$f(i) = f(1) = n = f'(1) = f'(i),$$

resulting in the desired $f(i) = f'(i)$. Because i is arbitrary, we may therefore conclude that the universal sentence (5.658) holds, which implies then (with the Equality Criterion for functions) $f = f'$. Here, f and f' were also arbitrary, so that the uniqueness part of the uniquely existential sentence in (5.656) holds as well. Since m was arbitrary, we may now further conclude that the universal sentence (5.656) holds. Consequently, there exists a unique function/sequence $\bar{d}$ with domain $\mathbb{N}$ and terms satisfying (5.655).

Next, we show that $\bar{d} : \mathbb{N} \to \mathbb{N}^1$, i.e. that $\mathbb{N}^1$ is a codomain of $\bar{d}$, which means that the range of $\bar{d}$ is included in $\mathbb{N}^1$. For this purpose, we verify the universal sentence

$$\forall f\,(f \in \mathrm{ran}(\bar{d}) \Rightarrow f \in \mathbb{N}^1), \tag{5.659}$$

taking an arbitrary constant f and assuming $f \in \mathrm{ran}(\bar{d})$ to hold. By definition of a range, there exists then a constant, say $\bar{m}$, such that $(\bar{m}, f) \in \bar{d}$. This shows that $\bar{m}$ is in the domain $\mathbb{N}$ of $\bar{d}$, which fact implies with (5.655) that $\bar{d}(\bar{m}) \in \mathbb{N}^1$ and $[\bar{d}(\bar{m})](1) = \bar{m}$ are both true. As we may write $(\bar{m}, f) \in \bar{d}$ in function notation as $f = \bar{d}(\bar{m})$, we obtain the desired $f \in \mathbb{N}^1$ via substitution. Since f is arbitrary, we may infer from this finding the truth of the universal sentence (5.659), and therefore the truth of the inclusion $\mathrm{ran}(\bar{d}) \subseteq \mathbb{N}^1$ (using the definition of a subset); thus, $\mathbb{N}^1$ is indeed a codomain of $\bar{d}$. We may now move on and prove that the reverse inclusion $\mathbb{N}^1 \subseteq \mathrm{ran}(\bar{d})$ holds, too. To do this, we establish accordingly the universal sentence

$$\forall f\,(f \in \mathbb{N}^1 \Rightarrow f \in \mathrm{ran}(\bar{d})), \tag{5.660}$$

letting $f \in \mathbb{N}^1$ $[= \bigtimes_{i=1}^{1} \mathbb{N}]$ be arbitrary, so that f is evidently a family with index set $\{1, \ldots, 1\}$ and terms satisfying $f_i \in \mathbb{N}$ for any $i \in \{1, \ldots, 1\}$. Since $1 \in \{1\}$ $[= \{1, \ldots, 1\}]$ is clearly true, we therefore have in particular $f_1 \in \mathbb{N}$, so that $\bar{d}(f_1) \in \mathbb{N}^1$ and $[\bar{d}(f_1)](1) = f_1$ follow to be true with (5.655). Let us observe here that $\bar{d}(f_1)$ is thus a family with the same index set $\{1, \ldots, 1\} = \{1\}$ (i.e., a function with the same domain) as the family/function f. We now use this fact and prove $f = \bar{d}(f_1)$ by means of the Equality Criterion for functions, that is, by proving

$$\forall i\,(i \in \{1\} \Rightarrow f_i = [\bar{d}(f_1)](i)). \tag{5.661}$$

Letting $i \in \{1\}$ be arbitrary, we evidently find $i = 1$, giving rise to the truth of the equations

$$f_i = f_1 = [\bar{d}(f_1)](1) = [\bar{d}(f_1)](i).$$

We thus obtain $f_i = [\bar{d}(f_1)](i)$, and as i was arbitrary, we may therefore infer from this equation the truth of (5.661) and consequently the truth of $f = \bar{d}(f_1)$. Writing this equation in the form $(f_1, f) \in \bar{d}$, we now see in light of the definition of a range that $f \in \mathrm{ran}(\bar{d})$ is also true. Because f is arbitrary, the universal sentence (5.660) follows therefore to be true, so that the inclusion $\mathbb{N}^1 \subseteq \mathrm{ran}(\bar{d})$ holds indeed. In conjunction with the reverse inclusion $\mathrm{ran}(\bar{d}) \subseteq \mathbb{N}^1$, this implies with the Axiom of Extension the equation $\mathrm{ran}(\bar{d}) = \mathbb{N}^1$, so that the function $\bar{d} : \mathbb{N} \to \mathbb{N}^1$ is a surjection.

Let us now prove that this surjection is also an injection. We let accordingly $m, m' \in \mathbb{N}$ be arbitrary, and we assume $\bar{d}(m) = \bar{d}(m')$ to be true.

On the one hand, $m, m' \in \mathbb{N}$ implies with (5.655) the truth of $\bar{d}(m) \in \mathbb{N}^1$, $[\bar{d}(m)](1) = m$, $\bar{d}(m') \in \mathbb{N}^1$ and $[\bar{d}(m')](1) = m'$. Thus, $\bar{d}(m)$ and $\bar{d}(m')$ are both families with index set $\{1, \ldots, 1\}$, i.e. functions sharing the same domain $\{1\}$. Because of the Equality Criterion for functions, the assumption $\bar{d}(m) = \bar{d}(m')$ implies the truth of $[\bar{d}(m)](i) = [\bar{d}(m')](i)$ for any $i \in \{1\}$, so that the evident fact $1 \in \{1\}$ implies

$$[m =] \quad [\bar{d}(m)](1) = [\bar{d}(m')](1) \quad [= m'].$$

We therefore find $m = m'$ to be true, and since m and m' are arbitrary, we may now conclude that the surjection $\bar{d} : \mathbb{N} \twoheadrightarrow \mathbb{N}^1$ is an injection from $\mathbb{N}$ to $\mathbb{N}^1$. Thus, $\bar{d}$ constitutes a bijection from $\mathbb{N}$ to $\mathbb{N}^1$, so that the existential sentence

$$\exists d\, (d : \mathbb{N} \rightleftarrows \mathbb{N}^1) \tag{5.662}$$

is true, as required by the base case.

In the induction step, we prove

$$\forall n\, (n \in \mathbb{N}_+ \Rightarrow [\exists d\, (d : \mathbb{N} \rightleftarrows \mathbb{N}^n) \Rightarrow \exists d\, (d : \mathbb{N} \rightleftarrows \mathbb{N}^{n+1})]), \tag{5.663}$$

letting $n \in \mathbb{N}_+$ be arbitrary and making the induction assumption that there exists a particular bijection

$$\bar{d} : \mathbb{N} \rightleftarrows \mathbb{N}^n,$$

so that the Bijectivity of inverse functions yields

$$\bar{d}^{-1} : \mathbb{N}^n \rightleftarrows \mathbb{N}.$$

Recalling that $\mathbb{N}$ and $\mathbb{N} \times \mathbb{N}$ are equinumerous, as shown in (5.619), there is also a particular bijection

$$\bar{D} : \mathbb{N} \rightleftarrows \mathbb{N} \times \mathbb{N},$$

and the Bijectivity of inverse functions gives us

$$\bar{D}^{-1} : \mathbb{N} \times \mathbb{N} \rightleftarrows \mathbb{N}.$$

To prove of the existence of a bijection $d : \mathbb{N} \rightleftarrows \mathbb{N}^{n+1}$, we use in the following Function definition by replacement to establish a function e with domain $\mathbb{N}^{n+1}$ such that

$$\forall g\, (g \in \mathbb{N}^{n+1} \Rightarrow \exists k, m\, (e(g) = \bar{D}^{-1}((k, m)) \wedge g = \bar{d}(k) \cup \{(n+1, m)\})), \tag{5.664}$$

and we will also show that this defines a bijection from $\mathbb{N}^{n+1}$ to $\mathbb{N}$, whose inverse will then be a bijection from $\mathbb{N}$ to $\mathbb{N}^{n+1}$, proving thereby the desired existential sentence. According to this method, we are required to prove the universal sentence

$$\forall g\,(g \in \mathbb{N}^{n+1} \Rightarrow \exists! y\,(\exists k, m\,(y = \bar{D}^{-1}((k,m)) \,\wedge\, g = \bar{d}(k) \cup \{(n+1, m)\}))). \tag{5.665}$$

We let $g \in \mathbb{N}^{n+1}$ be arbitrary, so that g constitutes a family with index set $\{1, \ldots, n+1\}$ whose terms satisfy

$$\forall i\,(i \in \{1, \ldots, n+1\} \Rightarrow g_i \in \mathbb{N}). \tag{5.666}$$

Evidently, the fact $n < n+1$ implies the inclusion $\{1, \ldots, n\} \subseteq \{1, \ldots, n+1\}$ with (4.260), giving rise to the restriction

$$g \restriction \{1, \ldots, n\} : \{1, \ldots, n\} \to \mathbb{N}$$

because of (3.566). This restriction is thus a family with index set $\{1, \ldots, n\}$, whose terms satisfy

$$\forall i\,(i \in \{1, \ldots, n\} \Rightarrow [g \restriction \{1, \ldots, n\}]_i \in \mathbb{N}), \tag{5.667}$$

since any $i \in \{1, \ldots, n\}$ is associated with the unique function value $[g \restriction \{1, \ldots, n\}]_i$ in the codomain $\mathbb{N}$, according to the Function Criterion. This finding demonstrates that $g \restriction \{1, \ldots, n\} \in \mathbb{N}^n$ holds, which Cartesian power is the domain of the inverse $\bar{d}^{-1}$, so that the function value

$$\bar{k} = \bar{d}^{-1}(g \restriction \{1, \ldots, n\}) \tag{5.668}$$

is a uniquely determined element of the codomain $\mathbb{N}$ of the inverse. This equation implies furthermore

$$\bar{d}(\bar{k}) = g \restriction \{1, \ldots, n\}. \tag{5.669}$$

with (3.678). As $n+1$ is clearly an element of the index set $\{1, \ldots, n+1\}$ of the family g, we can denote the corresponding term by

$$\bar{m} = g_{n+1}. \tag{5.670}$$

Having thus established the particular constants $\bar{k}$ and $\bar{m}$, we define now

$$\bar{y} = \bar{D}^{-1}((\bar{k}, \bar{m})) \tag{5.671}$$

and prove in addition that $\bar{k}$ and $\bar{m}$ satisfy the required equation

$$g = \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\}, \tag{5.672}$$

using the Equality Criterion for sets. For this purpose, we establish the universal sentence

$$\forall z \, (z \in g \Leftrightarrow z \in \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\}), \tag{5.673}$$

letting z be arbitrary. Regarding the first part ('$\Rightarrow$') of the equivalence, we assume $z \in g$ to be true. Being a family, g is a binary relation, so that the preceding assumption implies the existence of particular constants $\bar{a}, \bar{b}$ such that $(\bar{a}, \bar{b}) = z$ holds. Then, substitution yields $(\bar{a}, \bar{b}) \in g$, which shows that $\bar{a}$ is in the domain $\{1, \ldots, n+1\}$ of g. Here, we note that $\{1, \ldots, n+1\} = \{1, \ldots, n\} \cup \{n+1\}$ holds according to (4.241), so that the definition of the union of two sets gives us the true disjunction

$$\bar{a} \in \{1, \ldots, n\} \lor \bar{a} \in \{n+1\}.$$

We use this disjunction to prove the disjunction

$$z \in \bar{d}(\bar{k}) \lor z \in \{(n+1, \bar{m})\}, \tag{5.674}$$

by cases. The first case $\bar{a} \in \{1, \ldots, n\}$ implies in conjunction with $(\bar{a}, \bar{b}) \in g$ – by definition of a restriction – that $(\bar{a}, \bar{b}) \in g \restriction \{1, \ldots, n\}$ holds. Consequently, substitution based on (5.669) gives us $[z =]$ $(\bar{a}, \bar{b}) \in \bar{d}(\bar{k})$, and the disjunction (5.674) is then also true. The second case $\bar{a} \in \{n+1\}$ implies $\bar{a} = n+1$ with (2.169), which allows us to rewrite $(\bar{a}, \bar{b}) \in g$ as $\bar{b} = g(\bar{a}) = g_{n+1} = \bar{m}$. Thus, the two equations $\bar{a} = n+1$ and $\bar{b} = \bar{m}$ are true, so that $[z =]$ $(\bar{a}, \bar{b}) = (n+1, \bar{m})$ holds according to the Equality Criterion for ordered pairs. The resulting equation $z = (n+1, \bar{m})$ in turn implies $z \in \{(n+1, \bar{m})\}$ with (2.169), so that the disjunction (5.674) is again true. Having thus completed the proof by cases, we may infer from the truth of that disjunction the truth of $z \in \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\}$ by definition of the union of two sets, which finding proves the first part of the equivalence in (5.673).

Regarding the second part ('$\Leftarrow$'), we assume $z \in \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\}$ to be true, which evidently implies the truth of the disjunction (5.674). Based on this disjunction, we prove $z \in g$ by cases. In case of $z \in \bar{d}(\bar{k})$, we obtain $z \in g \restriction \{1, \ldots, n\}$ with (5.669) and therefore $z \in g$ by definition of a restriction, as desired. In the other case $z \in \{(n+1, \bar{m})\}$, which evidently implies $z = (n+1, \bar{m})$, we observe that (5.670) can be written as $(n+1, \bar{m}) \in g$, so that the desired consequent $z \in g$ follows to be true via substitution. Thus, the proof by cases is complete, and the finding $z \in g$ shows us then that the second part of the equivalence in (5.673) holds, too.

Since z was arbitrary, we may therefore conclude that the universal sentence (5.673) is true, which in turn implies the truth of the equation (5.672).

In conjunction with (5.671), this demonstrates the truth of the existential sentence

$$\exists k, m\,(\bar{y} = \bar{D}^{-1}((k,m)) \,\wedge\, g = \bar{d}(k) \cup \{(n+1,m)\}),$$

and this in turn shows that the existential part of the uniquely existential sentence in (5.665) holds.

To prove the uniqueness part, we let y and y' be arbitrary, assume the existential sentences

$$\exists k, m\,(y = \bar{D}^{-1}((k,m)) \,\wedge\, g = \bar{d}(k) \cup \{(n+1,m)\})$$
$$\exists k, m\,(y' = \bar{D}^{-1}((k,m)) \,\wedge\, g = \bar{d}(k) \cup \{(n+1,m)\})$$

to be true, and show that $y = y'$ is implied. Thus, the preceding assumptions give us particular constants $\bar{k}, \bar{m}$ and $\bar{k}', \bar{m}'$ satisfying

$$y = \bar{D}^{-1}((\bar{k}, \bar{m})) \,\wedge\, g = \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\}, \tag{5.675}$$
$$y' = \bar{D}^{-1}((\bar{k}', \bar{m}')) \,\wedge\, g = \bar{d}(\bar{k}') \cup \{(n+1, \bar{m}')\}. \tag{5.676}$$

The second parts of these conjunctions show in light of the definition of the union of a set system that $(n+1, \bar{m}) \in g$ and $(n+1, \bar{m}') \in g$ hold, which findings imply $\bar{m} = \bar{m}'$ due to the fact that g is a function. Furthermore, noting that the values $\bar{d}(\bar{k})$ and $\bar{d}(\bar{k}')$ are elements of the range/codomain $\mathbb{N}^n$ of the bijection $\bar{d}$ and constitute therefore families with common index set $\{1, \ldots, n\}$, we prove $\bar{d}(\bar{k}) = \bar{d}(\bar{k}')$ by means of the Equality Criterion for functions. To do this, we verify the universal sentence

$$\forall i\,(i \in \{1, \ldots, n\} \Rightarrow [\bar{d}(\bar{k})](i) = [\bar{d}(\bar{k}')](i)), \tag{5.677}$$

letting $i \in \{1, \ldots, n\}$ be arbitrary. Observing that $[\bar{d}(\bar{k})]_i = [\bar{d}(\bar{k})](i)$ and $[\bar{d}(\bar{k}')]_i = [\bar{d}(\bar{k}')](i)$ constitute terms/values of families/functions $\bar{d}(\bar{k})$ and $\bar{d}(\bar{k}')$, respectively, we can write the equations also as $(i, [\bar{d}(\bar{k})]_i) \in \bar{d}(\bar{k})$ and $(i, [\bar{d}(\bar{k}')]_i) \in \bar{d}(\bar{k}')$. Consequently, we obtain with the second parts of the conjunctions in (5.675) and (5.676), by definition of the union of a set system, $(i, [\bar{d}(\bar{k})]_i) \in g$ as well as $(i, [\bar{d}(\bar{k}')]_i) \in g$. These findings imply then $[\bar{d}(\bar{k})]_i = [\bar{d}(\bar{k}')]_i$ by definition of a function, so that the equation in (5.677) follows to be true via substitutions. Since i is arbitrary, we may now infer from this the truth of the universal sentence (5.677) and therefore the truth of the equality $\bar{d}(\bar{k}) = \bar{d}(\bar{k}')$. Then, being a bijection, $\bar{d}$ is an injection by definition, so that the preceding equation implies $\bar{k} = \bar{k}'$. In conjunction with the previously found equation $\bar{m} = \bar{m}'$, this gives us $(\bar{k}, \bar{m}) = (\bar{k}', \bar{m}')$ with the Equality Criterion for ordered pairs. Applying now substitution based on this equation, we obtain with the first parts of the conjunctions (5.675) and (5.676)

$$y = \bar{D}^{-1}((\bar{k}, \bar{m})) = \bar{D}^{-1}((\bar{k}', \bar{m}')) = y',$$

resulting in the desired equation $y = y'$. As y and y' were arbitrary, we may therefore conclude that the uniqueness part holds as well (besides the existential part), so that the proof of the uniquely existential sentence in (5.665) is complete. Since g was also arbitrary, the universal sentence (5.665) follows then to be true. We thus proved that there exists indeed a unique function e with domain $\mathbb{N}^{n+1}$ and values defined according to (5.664).

Our next task is to verify that $\mathbb{N}$ is a codomain of the function e, which means $\mathrm{ran}(e) \subseteq \mathbb{N}$. To prove this inclusion, we apply the definition of a subset and establish the equivalent universal sentence

$$\forall y\,(y \in \mathrm{ran}(e) \Rightarrow y \in \mathbb{N}). \tag{5.678}$$

We take an arbitrary y and assume that $y \in \mathrm{ran}(e)$ holds. By definition of a range, there exists then a constant, say $\bar{g}$, such that $(\bar{g}, y) \in e$ is true. This implies with the definition of a domain $\bar{g} \in \mathbb{N}^{n+1}$, so that the definition of e in (5.664) yields the true existential sentence

$$\exists k, m\,(e(\bar{g}) = \bar{D}^{-1}((k, m)) \wedge \bar{g} = \bar{d}(k) \cup \{(n+1, m)\}).$$

This means that there are constants, say $\bar{k}$ and $\bar{m}$, for which the equations $e(\bar{g}) = \bar{D}^{-1}((\bar{k}, \bar{m}))$ and $\bar{g} = \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\}$ are satisfied. Since we can use function notation to write $(\bar{g}, y) \in e$ in the form $y = e(\bar{g})$, we obtain $y = \bar{D}^{-1}((\bar{k}, \bar{m}))$ by means of substitution. Thus, y is a value in the codomain/range $\mathbb{N}$ of the bijection $\bar{D}^{-1}$, so that the implication in (5.678) is true. Here, y is arbitrary, so that the universal sentence (5.678) holds as well, and this means that the inclusion $\mathrm{ran}(e) \subseteq \mathbb{N}$ is true. We thus proved that $\mathbb{N}$ is indeed a codomain of the function e.

We can establish also the converse inclusion $\mathbb{N} \subseteq \mathrm{ran}(e)$, which will prove that e is a surjection. For this purpose, we verify

$$\forall y\,(y \in \mathbb{N} \Rightarrow y \in \mathrm{ran}(e)), \tag{5.679}$$

taking an arbitrary natural number y. Being thus an element of the domain of $\bar{D}$, the associated function value $\bar{D}(y)$ is then in the codomain $\mathbb{N} \times \mathbb{N}$ of $\bar{D}$. By definition of the Cartesian product of two sets, there are then particular elements $\bar{k} \in \mathbb{N}$ and $\bar{m} \in \mathbb{N}$ with $(\bar{k}, \bar{m}) = \bar{D}(y)$. Here, we note that the latter equation implies

$$y = \bar{D}^{-1}((\bar{k}, \bar{m})). \tag{5.680}$$

Moreover $\bar{k} \in \mathbb{N}$ shows that $\bar{k}$ is in the domain of $\bar{d}$, so that the corresponding function value $\bar{d}(\bar{k})$ is in the codomain $\mathbb{N}^n$ of $\bar{d}$. Consequently, $\bar{d}(\bar{k})$ constitutes a family with index set $\{1, \ldots, n\}$, i.e. a function with domain $\{1, \ldots, n\}$. Clearly, it is true that $n + 1 \notin \{1, \ldots, n\}$, which fact allows us to apply Concatenation of functions, where Proposition 3.177 shows then that

$$\bar{g} = \bar{d}(\bar{k}) \cup \{(n + 1, \bar{m})\} \tag{5.681}$$

constitutes a function with domain $\{1, \ldots, n\} \cup \{n + 1\}$. This domain is identical with $\{1, \ldots, n + 1\}$ according to (4.241), which means that $\bar{g}$ is a family with index set $\{1, \ldots, n + 1\}$. We can readily show that

$$\forall i \, (i \in \{1, \ldots, n + 1\} \Rightarrow \bar{g}_i \in \mathbb{N}) \tag{5.682}$$

also holds. We let

$$i \in \{1, \ldots, n + 1\} \quad [= \{1, \ldots, n\} \cup \{n + 1\}]$$

be arbitrary, so that $i \in \{1, \ldots, n\}$ or $i \in \{n + 1\}$ holds by definition of the union of two sets. In case of

$$i \in \{1, \ldots, n\} \quad [= \mathrm{dom}(\bar{d}(\bar{k}))],$$

we take the corresponding term $[\bar{d}(\bar{k})]_i = [\bar{d}(\bar{k})](i)$ and write for this equation $(i, [\bar{d}(\bar{k})]_i) \in \bar{d}(\bar{k})$. This implies $(i, [\bar{d}(\bar{k})]_i) \in \bar{g}$ with (5.681), which we can write in function notation as $[\bar{d}(\bar{k})]_i = \bar{g}(i)$. Using the notation for families, we can write this also in the form $g_i = [\bar{d}(\bar{k})]_i$. Recalling that $\bar{d}(\bar{k})$ is element the Cartesian product $\mathbb{N}^n$, we thus have in particular $[\bar{d}(\bar{k})]_i \in \mathbb{N}$, so that substitution based on the preceding equation yields $g_i \in \mathbb{N}$, as desired. In the other case of $i \in \{n + 1\}$, we evidently have $i = n + 1$, so that the ordered pair $(n + 1, \bar{m})$ is equal to the ordered pair $(i, \bar{m})$. Because $(n + 1, \bar{m})$ is an element of the union $\bar{g}$ in (5.681), we therefore find $(i, \bar{m}) \in \bar{g}$ to be true, which we can write as $\bar{m} = \bar{g}_i$. Recalling now the truth of $\bar{m} \in \mathbb{N}$, we obtain the desired $\bar{g}_i \in \mathbb{N}$ also in the second case. We thus proved the implication in (5.682), in which i is arbitrary, so that the universal sentence (5.682) follows to be true. In connection with the previously mentioned fact that $\bar{g}$ is a family with index set $\{1, \ldots, n + 1\}$, this means that $\bar{g}$ is element of the Cartesian power $\mathbb{N}^{n+1}$. Consequently,

$$\exists k, m \, (e(\bar{g}) = \bar{D}^{-1}((k, m)) \wedge \bar{g} = \bar{d}(k) \cup \{(n + 1, m)\})$$

follows to be true with (5.664). Because the equations (5.680) and (5.681) demonstrate the truth of the existential sentence

$$\exists k, m \, (y = \bar{D}^{-1}((k, m)) \wedge \bar{g} = \bar{d}(k) \cup \{(n + 1, m)\}),$$

which is satisfied by a unique constant y according to (5.665), it follows with the Criterion for unique existence that $y = e(\bar{g})$. Writing this in the form $(\bar{g}, y) \in e$, we now clearly see that y is in the range of e, which finding completes the proof of the implication in (5.679). Since y was arbitrary, the universal sentence (5.679) follows therefore to be true, and this implies the truth of the inclusion $\mathbb{N} \subseteq \mathrm{ran}(e)$ by definition of a subset. Together with the previously established converse inclusion $\mathrm{ran}(e) \subseteq \mathbb{N}$, this further implies $\mathrm{ran}(e) = \mathbb{N}$ with the Axiom of Extension, so that the function $e : \mathbb{N}^{n+1} \to \mathbb{N}$ is a surjection, by definition.

Next, we prove that the surjection $e : \mathbb{N}^{n+1} \twoheadrightarrow \mathbb{N}$ is also an injection. Letting g and g' be arbitrary and assuming $g, g' \in \mathbb{N}^{n+1}$ as well as $e(g) = e(g')$ to be true, we demonstrate in the following the truth of $g = g'$. By definition of the function e, the former assumption implies the truth of the existential sentences

$$\exists k, m\,(e(g) = \bar{D}^{-1}((k,m)) \,\wedge\, g = \bar{d}(k) \cup \{(n+1, m)\}),$$
$$\exists k, m\,(e(g') = \bar{D}^{-1}((k,m)) \,\wedge\, g' = \bar{d}(k) \cup \{(n+1, m)\}),$$

so that there are particular constants $\bar{k}, \bar{m}$ and $\bar{k}', \bar{m}'$ such that

$$e(g) = \bar{D}^{-1}((\bar{k}, \bar{m})) \,\wedge\, g = \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\},$$
$$e(g') = \bar{D}^{-1}((\bar{k}', \bar{m}')) \,\wedge\, g' = \bar{d}(\bar{k}') \cup \{(n+1, \bar{m}')\}.$$

In view of the first parts of these conjunctions and the assumed equation $e(g) = e(g')$, we obtain by means of substitutions

$$\bar{D}^{-1}((\bar{k}, \bar{m})) = \bar{D}^{-1}((\bar{k}', \bar{m}')),$$

and therefore $(\bar{k}, \bar{m}) = (\bar{k}', \bar{m}')$ with the injectivity of the bijection $\bar{D}^{-1}$. The Equality Criterion for ordered pairs gives us then the two equations $\bar{k} = \bar{k}'$ and $\bar{m} = \bar{m}'$, which allow us to perform further substitutions to the second parts of the preceding conjunctions, with the consequence that

$$g = \bar{d}(\bar{k}) \cup \{(n+1, \bar{m})\} = \bar{d}(\bar{k}') \cup \{(n+1, \bar{m}') = g'.$$

Consequently, we find $g = g'$ indeed to be true, and as g and g' are arbitrary, we may now conclude that the function $e : \mathbb{N}^{n+1} \twoheadrightarrow \mathbb{N}$ is an injection, and thus a bijection. Applying now once more the Bijectivity of inverse functions, we obtain the bijection

$$e^{-1} : \mathbb{N} \rightleftarrows \mathbb{N}^{n+1},$$

so that the existential sentence $\exists d\,(d : \mathbb{N} \rightleftarrows \mathbb{N}^{n+1})$ is true. Because n is arbitrary, we can therefore conclude that the induction step (5.663) holds, besides the base case, and this completes the proof of the universal sentence (5.654). Thus, $\mathbb{N}^n$ is by definition a countably infinite set for any positive natural number, as claimed in b).

Moreover, this implies that $\mathbb{N}^n$ is a countable set for any $n \in \mathbb{N}_+$. Recalling our previous finding that $\mathbb{N}^0$ is also countable and observing the truth of the disjunction $n = 0 \vee n \in \mathbb{N}_+]$ for an arbitrary $n \in \mathbb{N}$ in light of (2.310), we see that $\mathbb{N}^n$ is a countable set both in the case of $n = 0$ and in the case of $\mathbb{N}_+$. We may therefore conclude that Part a) of the theorem is also true. □

Exercise 5.65. Prove that every countably infinite set A and any of its Cartesian powers A^n for $n \in \mathbb{N}_+$ are equinumerous, that is,

$$\forall A, n\,([A \text{ is countably infinite } \wedge\ n \in \mathbb{N}_+] \Rightarrow A \sim A^n). \tag{5.683}$$

(Hint: Proceed similarly as in the proof of Theorem 5.159b), using now a particular bijection $\bar{D} : A \rightleftarrows A \times A$ based on (5.620).)

Corollary 5.160. *It is true for any countably infinite set A and for any positive natural number n that the n-th Cartesian power of A is itself countably infinite, that is,*

$$\forall A, n\,([A \text{ is countably infinite } \wedge\ n \in \mathbb{N}_+] \Rightarrow A^n \text{ is countably infinite}). \tag{5.684}$$

Proof. Letting A and n be arbitrary sets such that A is countably infinite and such that n is a positive natural number, we obtain on the one hand $\mathbb{N} \sim A$ according to Note 4.25, and on the other hand $A \sim A^n$ with (5.683). Then,

$$\mathbb{N} \sim A^n \tag{5.685}$$

follows to be true with the transitivity property (4.666), which finding shows that A^n is countably infinite (in light of Note 4.25). Here, A and n were both arbitrary, so that the stated universal sentence holds indeed. □

Exercise 5.66. Show for any countably infinite set A and for any natural number n that the n-th Cartesian power of A is countable, that is,

$$\forall A, n\,([A \text{ is countably infinite } \wedge\ n \in \mathbb{N}] \Rightarrow A^n \text{ is countable}). \tag{5.686}$$

(Hint: Use (2.310) and recall the beginning of the proof of Theorem 5.159)

The preceding results can be extended to more general forms of Cartesian products.

Theorem 5.161 (Countability of the Cartesian product of a finite sequence of countable sets). *It is true for any natural number n and for any sequence $A = (A_i \,|\, i \in \{1, \ldots, n\})$ of countable sets that the Cartesian product $\bigtimes_{i=1}^{n} A_i$ is countable, that is,*

$$\forall n \, (n \in \mathbb{N} \Rightarrow \forall A \, ([A = (A_i \,|\, i \in \{1, \ldots, n\}) \\ \wedge \, \forall i \, (i \in \{1, \ldots, n\} \Rightarrow A_i \text{ is countable})] \Rightarrow \bigtimes_{i=1}^{n} A_i \text{ is countable})). \tag{5.687}$$

Proof. We prove the theorem by means of mathematical induction. In the base case $n = 0$, the index set $\{1, \ldots, n\}$ is empty because of (4.239), so that so that we obtain for an arbitrary sequence $(A_i \,|\, i \in \{1, \ldots, n\})$ with (3.863) the true equation $\bigtimes_{i=1}^{n} A_i = \{\emptyset\}$. Being thus a singleton, the Cartesian product $\bigtimes_{i=1}^{n} A_i$ is finite (see Corollary 4.100) and therefore countable. In the induction step, we take an arbitrary natural number n and make the induction assumption that the Cartesian product $\bigtimes_{i=1}^{n} A_i$ is countable for any sequence $A = (A_i \,|\, i \in \{1, \ldots, n\})$ of countable sets. We then take an arbitrary sequence $A = (A_i \,|\, i \in \{1, \ldots, n+1\})$ such that A_i is countable for every index $i \in \{1, \ldots, n+1\}$. Consequently, we obtain the equivalence

$$\bigtimes_{i=1}^{n+1} A_i \sim \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}$$

with (4.681), so that there exists a bijection from the Cartesian product $\bigtimes_{i=1}^{n+1} A_i$ to the Cartesian product $\left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}$, say $\bar{f}$. This bijection constitutes then in particular an injection, that is,

$$\bar{f} : \bigtimes_{i=1}^{n+1} A_i \hookrightarrow \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}.$$

Since all terms of the restricted sequence

$$A \upharpoonright \{1, \ldots, n\} = (A_i \,|\, i \in \{1, \ldots, n\})$$

are evidently terms of the sequence A and thus countable, it follows with the induction assumption that the Cartesian product $\bigtimes_{i=1}^{n} A_i$ is countable. Since the term A_{n+1} of the sequence A is also countable, we have by virtue of the Countability of the Cartesian product of two countable sets that $\left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1}$ is countable. According the Countability Criterion (4.652), there is then an injection from that Cartesian product to $\mathbb{N}$, say

$$\bar{g} : \left[\bigtimes_{i=1}^{n} A_i\right] \times A_{n+1} \hookrightarrow \mathbb{N}.$$

Due to the Injectivity of the composition of two injections, it follows that

$$\bar{g} \circ \bar{f} : \bigtimes_{i=1}^{n+1} A_i \hookrightarrow \mathbb{N},$$

demonstrating the existence of an injection from $\bigtimes_{i=1}^{n+1} A_i$ to $\mathbb{N}$. We therefore see in light of the Countability Criterion (4.652) that the Cartesian product $\bigtimes_{i=1}^{n+1} A_i$ is countable. Since the sequence A and the natural number n are arbitrary, we can now infer from the preceding finding that the induction step holds (besides the base case), so that the proof of the theorem via mathematical induction is complete. □

Corollary 5.162. *It is true for any countable set A and for any natural number n that the n-th Cartesian power of A is also countable, that is,*

$$\forall A, n\,([A \text{ is countable } \wedge\ n \in \mathbb{N}] \Rightarrow A^n \text{ is countable}). \tag{5.688}$$

Proof. Letting A and n be arbitrary sets such that A is countable and such that n is a natural number, we have that A defines the constant sequence

$$\{1, \ldots, n\} \times \{A\} = (A_i \,|\, i \in \{1, \ldots, n\}),$$

for which $A_i = A$ holds for every $i \in \{1, \ldots, n\}$ according to Corollary 3.154. Evidently, the countability of A implies then the countability of A_i for all $i \in \{1, \ldots, n\}$ via substitution, so that we can apply the preceding Theorem 5.161 to infer from this the countability of the Cartesian product $\bigtimes_{i=1}^{n} A_i$. Thus, the Cartesian power A^n is countable, where A and n are arbitrary, so that the universal sentence (5.688) follows now to be true. □

Before continuing our study concerning the countability of Cartesian products, we use the preceding corollary to establish the following corollary, which in turn serves as a basis for the subsequent theorem.

Corollary 5.163. *It is true for any countable set Y that the set $Y^{<\mathbb{N}_+}$ of all sequences in Y with domain $\{1, \ldots, n\}$ for some $n \in \mathbb{N}$ constitutes a countable set.*

Proof. Letting Y be an arbitrary countable set, we recall from Exercise 4.32 that the set $Y^{<\mathbb{N}_+}$ is identical with the union $\bigcup_{n=0}^{\infty} Y^n$ of the sequence $(Y^n)_{n \in \mathbb{N}}$ of Cartesian powers of Y. Here, we observe that the index set $\mathbb{N}$ is countably infinite (see Corollary 4.137) and thus countable. Furthermore, (5.688) shows for the given countable set Y that $n \in \mathbb{N}$ implies the countability of Y^n for any $n \in \mathbb{N}$. We may therefore use (5.651) to infer from these findings that the union $Y^{<\mathbb{N}_+} = \bigcup_{n=0}^{\infty} Y^n$ is countable. Since Y was initially arbitrary, we may then conclude that the corollary holds. □

Theorem 5.164 (Countability of the set of all finite subsets of a countable set). *It is true for any countable set Y that there exists a unique set (system)*

$$\mathcal{X} = \{X : X \subseteq Y \,\wedge\, X \text{ is finite}\} \tag{5.689}$$

consisting of all finite subsets of Y, and this set is countable.

Proof. We take an arbitrary set Y and assume it to be countable. We then see in light of the Axiom of Specification and the Equality Criterion for sets that there exists a unique set $\mathcal{X}$ such that

$$\forall X\,(X \in \mathcal{X} \Leftrightarrow [X \in \mathcal{P}(Y) \,\wedge\, X \text{ is finite}]). \tag{5.690}$$

By definition of a power set, $X \in \mathcal{P}(Y)$ is equivalent to $X \subseteq Y$ for any X, so that $\mathcal{X}$ represents the set (5.689) consisting of all finite subsets of Y. Next, we apply Function definition by replacement to establish a unique function f with domain $Y^{<\mathbb{N}_+}$ such that

$$\forall s\,(s \in Y^{<\mathbb{N}_+} \Rightarrow f(s) = \mathrm{ran}(s)). \tag{5.691}$$

For this purpose, we verify the universal sentence

$$\forall s\,(s \in Y^{<\mathbb{N}_+} \Rightarrow \exists! y\,(y = \mathrm{ran}(s))). \tag{5.692}$$

Letting s be arbitrary in $Y^{<\mathbb{N}_+}$, the range of s is a uniquely specified set, so that the uniquely existential sentence is true according to (1.109). Since s is arbitrary, (5.692) follows to be true, so that there exists indeed a unique function function with domain $Y^{<\mathbb{N}_+}$ satisfying (5.691).

We now prove that the set (5.689) constitutes the range of the function f. To do this, we apply the Equality Criterion for sets and establish the equivalent universal sentence

$$\forall y\,(y \in \mathrm{ran}(f) \Leftrightarrow y \in \mathcal{X}). \tag{5.693}$$

We let y be arbitrary, and we prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in \mathrm{ran}(f)$ to be true. By definition of a range, there is then a constant, say $\bar{s}$, such that $(\bar{s}, y) \in f$. This yields with the definition of a domain $\bar{s} \in Y^{<\mathbb{N}_+}$, so that $\bar{s}$ is a sequence in Y. Thus, Y is a codomain of $\bar{s}$, which means that the inclusion $\mathrm{ran}(\bar{s}) \subseteq Y$ holds. Because $\bar{s} \in Y^{<\mathbb{N}_+}$ implies $f(\bar{s}) = \mathrm{ran}(\bar{s})$ with (5.691), we obtain from the preceding inclusion by means of substitution $f(\bar{s}) \subseteq Y$. Writing the previous finding $(\bar{s}, y) \in f$ now in function notation, we obtain $y = f(\bar{s})$ and therefore $y \subseteq Y$, so that $y \in \mathcal{P}(Y)$ follows to be true by definition of a power set. Moreover, $\bar{s} \in Y^{<\mathbb{N}_+}$ implies that $\mathrm{ran}(\bar{s})$ is finite due to (4.605). Applying now substitutions based on the equations $y = f(\bar{s}) = \mathrm{ran}(\bar{s})$, we thus have that y is finite, which implies in conjunction with $y \in \mathcal{P}(Y)$ that y is an element of $\mathcal{X}$, according to (5.690). This finding completes the proof of the first part of the equivalence in (5.693).

Concerning the second part ('$\Leftarrow$'), we conversely assume $y \in \mathcal{X}$ to hold, so that y is evidently a finite subset of Y. By definition of a finite set, there exist then a natural number, say $\bar{n}$, and a bijection from $\{1, \ldots, \bar{n}\}$ to y, say $\bar{c}$. Thus, $\bar{c}$ is a surjection, so that the codomain y equals the range of $\bar{c}$. The truth of the preceding inclusion $y \subseteq Y$ implies now via substitution the inclusion $\mathrm{ran}(\bar{c}) \subseteq Y$, which demonstrates that Y is also a codomain of $\bar{c}$. Consequently, the function $\bar{c}: \{1, \ldots, \bar{n}\} \to Y$ is an element of $Y^{\{1,\ldots,\bar{n}\}}$, which fact evidently implies $\bar{c} \in Y^{<\mathbb{N}_+}$ with the specification of that set in (4.395). This sequence $\bar{c}$ is associated with the function value $f(\bar{c}) = \mathrm{ran}(\bar{c})$ according to (5.691), so that the previously found equality $y = \mathrm{ran}(\bar{c})$ yields $y = f(\bar{c})$. We can write this also in the form $(\bar{c}, y) \in f$, which gives us with the definition of a range the desired consequent $y \in \mathrm{ran}(f)$ of the implication '$\Leftarrow$' in (5.693).

We thus completed the proof of the equivalence in (5.693), in which y is arbitrary, so that the universal sentence (5.693) follows now to be true. This in turn completes the proof of the equality $\mathrm{ran}(f) = \mathcal{X}$, which shows that the function f is a surjection from $Y^{<\mathbb{N}_+}$ to $\mathcal{X}$, that is,

$$f : Y^{<\mathbb{N}_+} \twoheadrightarrow \{X : X \subseteq Y \wedge X \text{ is finite}\}.$$

Let us observe now that the assumed countability of Y implies the countability of the set $Y^{<\mathbb{N}_+}$, according to Corollary 5.163. Since Exercise 4.32d) shows that $Y^{<\mathbb{N}_+}$ is nonempty even for $Y = \emptyset$, it follows with the Countability Criterion (4.653) that there exists a surjection from $\mathbb{N}$ to $Y^{<\mathbb{N}_+}$, say

$$g : \mathbb{N} \twoheadrightarrow Y^{<\mathbb{N}_+}.$$

Due to the Surjectivity of the composition of two surjections, we obtain therefore from f and g the surjection

$$f \circ g : \mathbb{N} \twoheadrightarrow \{X : X \subseteq Y \wedge X \text{ is finite}\}.$$

In view of the Countability Criterion (4.653), the existence of such a surjection implies that the set (5.689) of all finite subsets of the countable set Y is countable. Since Y was arbitrary, we may therefore conclude that the stated theorem is true. □

The following theorem generalizes the Countability of the Cartesian product of a finite sequence of countable sets, by allowing the index set to be any finite set rather than a specific initial segment of $\mathbb{N}_+$.

Theorem 5.165 (Countability of the Cartesian product of a family of countable sets with finite index set). *It is true that*

a) the Cartesian product of any family of sets $A = (A_j)_{j\in J}$ having a finite index set J is equivalent to the Cartesian product of the sequence $([A \circ c]_i \,|\, i \in \{1, \dots, n\})$ for some natural number n and for some bijection c from $\{1, \dots, n\}$ to J, that is,

$$\forall J, A\,([J \text{ is finite } \wedge\ A = (A_j)_{j\in J}] \tag{5.694}$$
$$\Rightarrow \exists n, c\,(n \in \mathbb{N} \wedge c : \{1, \dots, n\} \rightleftarrows J \wedge \bigtimes_{j\in J} A_j \sim \bigtimes_{i=1}^{n} [A \circ c]_i)).$$

b) if all terms of a family of sets $(A_j)_{j\in J}$ having a finite index set are countable, then the Cartesian product of this family is countable, that is,

$$\forall J, A\,([J \text{ is finite } \wedge\ A = (A_j)_{j\in J} \tag{5.695}$$
$$\wedge\ \forall j\,(j \in J \Rightarrow A_j \text{ is countable})] \Rightarrow \bigtimes_{j\in J} A_j \text{ is countable}).$$

Proof. We let J and A be arbitrary sets, assume J to be finite, and assume moreover that A is a family of sets $(A_j)_{j\in J}$ with index set J. By definition of a finite sets, there are then constants, say $\bar{n}$ and $\bar{c}$, such that $\bar{n}$ is a natural number and $\bar{c}$ a bijection from $\{1, \dots, \bar{n}\}$ to J. Since we may view the family A as being a function $A : J \to \text{ran}(A)$, we have that the composition of A and $\bar{c}$ constitutes the function $A \circ \bar{c} : \{1, \dots, \bar{n}\} \to \text{ran}(A)$, according to Proposition 3.178. Thus, we can write this composition as the sequence $([A \circ \bar{c}]_i \,|\, i \in \{1, \dots, \bar{n}\})$. It remains for us to establish the equivalence $\bigtimes_{j\in J} A_j \sim \bigtimes_{i=1}^{\bar{n}} [A \circ \bar{c}]_i$, that is, to demonstrate the existence of a bijection from the former to the latter Cartesian product.

For this purpose, we apply first Function definition by replacement to establish a unique function F with domain $\bigtimes_{j\in J} A_j$ such that

$$\forall f\,(f \in \bigtimes_{j\in J} A_j \Rightarrow F(f) = f \circ \bar{c}), \tag{5.696}$$

which task requires the verification of the universal sentence

$$\forall f\,(f \in \bigtimes_{j\in J} A_j \Rightarrow \exists! y\,(y = f \circ \bar{c})). \tag{5.697}$$

Letting f be arbitrary and assuming $f \in \bigtimes_{j\in J} A_j$, we have by definition of the Cartesian product of a family of sets that f is a family with index set J, which is a function with domain J (and codomain, say, $\mathrm{ran}(f)$). Consequently, the composition of f and the bijection $\bar{c} : \{1, \ldots, \bar{n}\} \to J$ constitutes the function $f \circ \bar{c} : \{1, \ldots, \bar{n}\} \to \mathrm{ran}(f)$ (using again Proposition 3.178). This is a uniquely specified set, so that the uniquely existential sentence in (5.697) follows to be true with (1.109). Since f is arbitrary, we may therefore conclude that the universal sentence (5.697) also holds, which in turn implies the existence of a unique function F with domain $\bigtimes_{j \in J} A_j$ and values defined by (5.696).

Next, we establish the Cartesian product $\bigtimes_{i=1}^{\bar{n}} [A \circ \bar{c}]_i$ as the range of that function. To do this, we apply the Equality Criterion for sets and prove

$$\forall y \, (y \in \mathrm{ran}(F) \Leftrightarrow y \in \bigtimes_{i=1}^{\bar{n}} [A \circ \bar{c}]_i), \tag{5.698}$$

taking an arbitrary set y. We prove the first part ('$\Rightarrow$') of the equivalence directly, assuming $y \in \mathrm{ran}(F)$ to be true. By definition of a range, there exists then a particular constant $\bar{f}$ such that $(\bar{f}, y) \in F$. By definition of a domain, we thus have $\bar{f} \in \bigtimes_{j \in J} A_j$ [$= \mathrm{dom}(F)$], so that the definition of the function F in (5.696) yields $F(\bar{f}) = \bar{f} \circ \bar{c}$. Furthermore, $\bar{f} \in \bigtimes_{j \in J} A_j$ evidently means that $\bar{f}$ is a family with index set J and terms satisfying

$$\forall j \, (j \in J \Rightarrow \bar{f}_j \in A_j). \tag{5.699}$$

Thus, $\bar{f}$ is a function from J to $\mathrm{ran}(\bar{f})$, so that the composition $F(\bar{f})$ is a function from $\{1, \ldots, \bar{n}\}$ to $\mathrm{ran}(\bar{f})$, and this is a family/sequence with index set $\{1, \ldots, \bar{n}\}$. Noting that we can write the previous finding $(\bar{f}, y) \in F$ in function notation as $y = F(\bar{f})$, we thus have that y is a family with index set $\{1, \ldots, \bar{n}\}$. We can also show that the terms of y satisfy

$$\forall i \, (i \in \{1, \ldots, \bar{n}\} \Rightarrow y_i \in [A \circ \bar{c}]_i). \tag{5.700}$$

Letting i be arbitrary and assuming $i \in \{1, \ldots, \bar{n}\}$, it is true that i is in the domain of $\bar{c} : \{1, \ldots, \bar{n}\} \to J$, so that the associated function value $\bar{c}(i)$ is in the codomain J (according to the Function Criterion). Thus, $\bar{c}(i)$ is an element of the domain J of the function $\bar{f}$, which fact gives us the value $\bar{f}(\bar{c}(i)) \in A_{\bar{c}(i)}$ with (5.699). In view of the previously established equations, we can write on the one hand

$$\bar{f}(\bar{c}(i)) = [\bar{f} \circ \bar{c}](i) = [F(\bar{f})]_i = y_i,$$

and on the other hand

$$A_{\bar{c}(i)} = A(\bar{c}(i)) = [A \circ \bar{c}]_i,$$

allowing us to infer from $\bar{f}(\bar{c}(i)) \in A_{\bar{c}(i)}$ the truth of the desired consequent $y_i \in [A \circ \bar{c}]_i$ of the implication in (5.700). Here, i was arbitrary, so that the universal sentence (5.700) follows to be true. In conjunction with the fact that y is a family with index set $\{1, \ldots, \bar{n}\}$, this implies now that y is in the Cartesian product $\bigtimes_{i=1}^{\bar{n}} [A \circ \bar{c}]_i$, proving the implication '$\Rightarrow$' in (5.698).
